The captain submits quietly to all the preparations, shrugging his shoulders without articulating a word. In a few minutes his irons were removed, and he was left alone in his cell, the door of which, for the first time, was wide open. Several times the unfortunate man rises up and falls again on the ground; the confinement of nearly fifty years in a sitting posture has nearly deprived him of the use of his limbs: at length, after a quarter of an hour spent in useless efforts, he succeeded in sustaining himself upright, and, with a faltering step, advances from the bottom of his dungcon towards the door. His first movement is to look up to the heavens: he cries out with an ecstasy of joy, "Oh, how beautiful!" During the whole day he is constantly in motion, running up stairs and descending immediately afterwards; the same expression constantly on his lips, "Oh, how beautiful! how com-fortable!" Towards evening he enters quibecomes useful in the establishment, exercising a certain degree of authority over rible delusions so common in our days. Endowed with a feeble intelligence, and easily seduced by fanatical impressions, he had conceived, in his severe and mystic meditations, that God had chosen him for " the baptism of blood;" that is to say, "for the duty of killing his Christian brethren on this earth, in order to send them more speedily to enjoy the pleasures eternally reserved for the select of God." This burlesque idea gave rise to an atrocious crime. He commenced his homicidal mission by plunging a knife into the heart of one of his own children. Declared mad by a court of justice, and conducted to Bicetre, he was tormented by the same frantic delirium for a long series of year. At length came calm, but without reason. He is now dull and silent; a fleshless spectre seated on a stone; his emaciated limbs are still loaded with the same chains which he formerly bore, and which he is now unable to sustain; they were left on, perhaps, as much through forgetfulness as with a desire to punish the cruel actions which brought bim to the house of the mad. For him there was no hope of amelioration. Pinel had him transported into one of the beds of the infirmary. His legs are so stiff and contracted that he for repeated excesses and is unable even to extend them. However, sipated his feeble resource

The third presents a striking contrast. He is a man in the flower of his age; his eyes are sparkling, his language is elevated, and his manners are dramatic. In his youth he was a man of letters. Endowed with a sweet and gay temper, and a brillian Imagination, he spun many a web of love and honour, which he transferred to his impassioned romances. He wrote without ceasing; and in order to bestow more time on his literary occupations, he at length shut himself up completely in his chamber, passing often the day without food and the night without sleep. In this state an unfortunate passion intervened to exalt his ideas still further, and finish what a too vivid imagination had already commenced. He became desperately in love with a young girl in the neighbourhood, good and virtuous, as they are all, in the beginning, but who soon became fatigued of the unhappy author. She was faithless, and did not even leave the consolation which might arise ctly into his cell; sleeps on a better bed, from a doubt. During a year his soul was expressly prepared for him. During a lapse a prey to bitter concentrated grief; when of two years more, spent at Bicetre, he even suddenly struck with the ridicule of weening for one so unworthy of his love, he passed from one extremity to another, and gave the other patients, who willingly submit himself up, without hounds, to every excess, themselves to his orders. His companion in It was in the midst of one of these orgies captivity is almost equally worthy of com- that reason broke down; and, conducted to passion; an old French officer who has been Bicetre in a state of furious mania, he was confined in irons for thirty-six years, during thrown, about twelve years ago, into his which he laboured under one of those ter-dungeon, where he still vainly endeavours to rend asunder the irons that bind him down.

> This patient was rather turbulent than dangerous; muchle to comprehend the good he was about to receive, nothing but force compelled him to leave his chains; once liberated, he commenced running in a circle round the court, until he fell exhausted and breathless to the ground; the care of Pinel, and the fastering attention which he bestowed on this patient in particular, soon brought back his reason; but unfortunately he must return to the bosom of society, at that time so agitated; the event was not long doubtful; he cast himself iato political agitations with all the ardour of his youthful passion, and on the eighth Thermidor his head fell upon the scaffold.

Pinel now enters the fourth cell; it is that of Chevigné, whose release from captivity is perhaps the most memorable fact of this remarkable day. Chevigné was a soldier in the French guards, and had only a single fault, that of being too much addicted to drunkenness: once elevated by wine he became quarrelsome, violent, and was the more dangerous, that his strength me prodigious. He was dismissed for

the a state of shame and poverty, which soon [89. During the period of famine he leaves overcame reason. This madness he thought Bicetre every morning, and returns with himself a general officer, and would strike an abundant supply of provisions which every one that did not immediately recognise his rank. It was at the termination of one of these quarrels, that he was brought to Bicilre in the most furious state of excitement; there he remained ironed for ten year more carefully so than his companions, as he had more than once broken his chains by the simple force of his arms; once, it is said, having procured a few minutes liberty, he defied all the guardians united together to replace him in his cell, before he had made them pass under his leg; and actually performed this inconceivable feat upon eight men who attempted to make themselves master of his person; from that day his strength became a proverb at Biectre.

Pinel had already discovered in this man the germ of a good disposition, concealed beneath an excitement which was constantly kept up by the cruel treatment he was submitted to. He promised to ameliorate his condition in a short time, and these few words of comfort at once rendered him more calor. Pivel announced to him the joyful news that he was about to leave his irons. "To prove that I have confidence in you," said he, " and regard you as one unhappy strangers. born to do good, you shall lend your assistance in delivering these unfortunate creaso tures, who have not their reason as you have, and if you conduct yours, if as I expeet and hope, I will take you into my own service, and promise to protect you for the rest of your life.

Never was a more sadden or complete revolution seen in the formun intellect. The guardians themselves are scized with asto-; nishment and respect at the example of thirty-five years before the publication of Chevigne. His chains are yet scarcely removed from his limbs, and behold him careful, respectful, following with an attentive eye all the movements of Pinel, and executing his orders with promptitude and address. Behold him pouring forth words of peace, consolation, and reason, to his nufortunate fellow sufferers,- he, who a few minutes back was sunk below their level. but now stands before them elevated by the proud consciou ness of liberty. This man, whom chains had demoralized during the fairest portion of his manhood, and who, doubtless, would have dragged along the whole course of his existence in this fearful agony of intellectual suffering, this man becomes henceforward a model of good conduct and gratitude; more than once, in the most dangerous storms of the revolution, he saved the life of his protector; on one occasion, particularly, he rescued him from the bands of a band of malefactors, who were wing him to the lamp* as an elector of in the cost pats of the lamps—

gold could not purchase at that moment of universal want; in a word, his whole life is a series of acts of devotion to his liberator.

Chevigné is more than a grand and sublime lesson for the science; he is a conquest made to humanity of an honest and faithful mind from the infamous barbarity under

which it had given way.

Next to Chevigné, in the neighbouring cell, are three unfortunate Prussian soldiers, chained there for a long series of years: no one knows the motive in which such rigorous treatment has originated; they are commonly inoffensive and calm, becoming animated from time to time in a language which nobody understands. The moment they perceive round them any strange assemblage of persons or things, they imagine themselves the object of hostile intentions, and oppose the removal of their irons with the utmost violence; when freed, they are nawilling to quit their prison, and remain fixed in the position to which they have been so long accustomed. The sentiment of liberty, so cherished by everything human, seems totally extinct in the bosom of these

[What a lesson in some of these facts!]

Die Erscheinungen und Gesetzen des Organischen, Lenens Von Gottfried Rien-HOLD TREVIRANUS. 2 B. (The Phenosiena and Laws of Organic Life, Se.)

The Biology of Treviranus was commenced the present work; and volume after volume slowly appeared, unfolding the fruits of persevering research, of continued experiments. and of genius such as has rarely been engaged in studying Life. The productions of the human intellect, in their development, -unlike the growth of trees, where the operation of every successive year makes natural additions to each part, and helps to carry out the perfect idea of their form .do not constitute the permanent materials of ultimate maturity; for the mind in its progressive investigation of phenomena, after endl as essays, and innumerable observations, at last discovers one point of view, before which all former conceptions are rendered imperfect, and are at once broken up and superseded. In the process of generalization, the last principle includes the former, as one serpent swallows up another. that serpent being itself swallowed by a later and a mightier. Hence, Treviranus found

that the investigations which he made in she progress of his own work, as well as the indicates, we must an attem in beings, discoveries of others, rendered changes newhere they lie haver to the large." cessary in the early volumes, before the last were begun. This consideration led him at last to abandon the attempt to complete the "Biology," which is instinct with genius, and, so far as it extends, is the most comprehensive, scientific, and profound investigation of vital phenomena, which has been published since the days of Aristotle. In the present two volumes he has presented the entire circle of physiological laws and their phenomena in a compressed form ;-

"The Biology," he remarks, "contains the history of the distribution of organic far if all the obscurities of these questions my labours, a too distant goal."

eulogizing the genius of the Germans, de- But to proceed with our translation :clares that nothing but the difficulty of protheir language has prevented many of their stition and unbelief. What is the earth, their language has prevented many of their with all its treasures, for the great mass of best works from becoming known to us, mankind, but a stage filled with forms withand shut out from this country some of their out any earnest signification? They pass Blumenbach had not been written in Laun, and if the work of Tiedemann had not been their language. He dies in abundance, sight translated into French, we might have sighing over the emptiness of existence and should not only hold the "Biology" of Treviranus in less esteem than it deserves, but should hardly know of its existence.

With what enthusiasm Treviranus has devoted his time to the study of life the introduction will show : -

" If," he exclaims, "the study of nature generally is one of the noblest occupations of man, the subject of our investigations especially deserves the attention of every educated person. To know himself, is the sage's first law. But no man can know himself.-can know either his mind or his body,-who does not compare himself with kindred beings. For ourselves, only single parts are susceptible of thorough investi-

Treviranus is evidently one of those men who think that nothing can be more pitiable than the observance of that severity of language which some practical writers desire to maintain by avoiding all expressions of feeling, and cautiously excluding all indulgence in the power of the imagination, not only in the formation of their style, but in their modes of thinking. None are too exact, though a few may be too cold. By referring to the Greek writers, to Bacon, and to Cuvier, it may be seen that nature is not exposed to view only in the form of anatomical prebeings, and of the revolutions of living na. parations. Simply to analyze is to leave ture. I have excluded this from the present, our work imperfect. The machine may be work, because it would have extended too advantageously taken to pieces; but to perhad been critically examined, and because ceive its operations the parts must be rein this department I had no personal obser- joined, when the contemplation of its evovations to add. Besides, the sun which was lutions will often excite the philosopher to with me in the morning, when I went to my renewed efforts, and may usefully imbue earlier work, now hastens to its setting. It him with a highly poetic feeling. The vois not the time for me to fix, as the aim of lumes of Treviranus combine a mathematical accuracy of reasoning, with the finest Byron, in an address to Goethe, while sense of what is animating in philosophy.

them from immortality. Certain it is that elevated and ennobled, preserved from onethe difficulties of acquiring a knowledge of sidedness," and restrained alike from superbrightest thoughts. If the Physiology of before their eyes without touching the in-Blumenbach had not been written in Latin, ward sense. They speak, but man is insenremained ignorant of those valuable works the monotony of day. The student and unto this day. It is not, therefore, astonish- lover of nature is in a world ever presenting ing that the profession in this kingdom him with fresh views, which would never let him grow weary though he lived through centuries All in it has for him a signification. He is no where a stranger, and no part of the earth is for him without charms, since he ever meets with nature. So did Stetter, caraptured with the study of the sciences, feel as happy in the desert Kamschatka as in a Paradise. He wished himself banished to Siberia, in order to quench his thirst for discovery.

"Such a spiritual life in the bosom of nature, cannot but nourish and sharpen the sense of truth and simplicity. Therefore was the natural philosopher J. Aug

^{* &}quot; Einseitigkeit" has been trans English before. Prejudice," @: ness," does not exactly east

his brother, the late Melchior, raised agents every interlandout thinker. An eld poet says, 'He who makes verses, thinks only on them, not on lying and deceit." This may be true. But it is not the same, to think of no unworthy things because the attention is withdrawn by other objects, or became the moral sense is elevated by constant occupation on noble subjects. can be no great poet, but there are many superficial natural philosophers, without nobility of thought. Yet he who attains to the heights of Parnassus, was already a great man ere he climbed. He who is not made morally better by the study of nature, has not been impelled thereto by an inward tendency and constraint. This does not hold of the study of living nature only, but of that more emphatically. A man may possess profound knowledge in mineralogy, chemistry, and physics, without reflecting on the great questions, what and whence are we ourselves? Whither go we? But he can never arrive at any certainty as to the origin of the infusoria without stumbling on principles connected with those questions. Furthermore, no science is more intimately connected with other sciences than the science of life, therefore no one is less likely to fall into narrow mindedness, than he who Vision, seeks to fathout this in all its parts. with all its various modifications in the various animals, can only be completely comprehended by him who is a proficient in optics, nor hearing without a profound know-The explanation of the ledge of acoustics processes of respiration, digestion, nutrition, and the development of animal heat, rests on chemical grounds. The doctrine of the geographical distribution of plants and ani mals, is strictly connected with physical geography and meteorology, as is the history of the former changes of living nature, with geology and archeology. And he who is master of these and many more collateral sciences, cannot proceed far in the knowledge of life unless he he a philosopher.

"In every living thing there may be recognised a forming and working of every single part for all the rest, and for the whole; also proximately for the species, and for other species. This design is only possessed by the living. Yet it betrays itself in the smallest of these, only by the magnifying-glass of perceptible parts. In all external movements of animals, and even of many plants, there is likewise an appearance of voluntary, and on the other hand, of necessary destination to action. We find this combination of freemm and necessity, especially in the exercise of the instincts of animals. All observations of that design, and of this appaat spontaneity in endlessly various modiand all reflection thereupon, lead tion."

What follows is somewhat obscure, yet it will be received with respect from the lips of one who has devoted a long life to the study of physiology; who has been a fearless champion of truth; who never wrote a Bridgewater Treatise; and who would never sing a hired hymn even to the Creator .-

"Therefore," says this enthusiastic man, "were all who have investigated the phenomena of nature, men of deep religious feeling. I will only recal to memory Swammerdam, Bonnet, and Linnæus. Their piety indeed wore the costume of their education and their age. But if Swammerdam appears doating in the theological applications which he made of his great zootomical discoveries, and worthy of pity when sitting at the feet of Bourignona, gloomy enthusizet: if Bonnet and many other naturalists of the last century, mistook their own wisdom for that of the Creator, they nevertheless sought, although mistakenly, that higher light whose reflection they had caught. He who fails to recognise this light in nature, sees unconsolable nothing in it, but an eternal circle of rising and setting. who in dreams, or in poesy, seeks words which answer to the light, finds not truth but a phantasm of his own brain. But to him who enters on the right paths by the study of living nature, its muse herself will be a conductress, who remains true when all abandon him; and like Leucothea to the shipwrecked, will reach a holy veil when the waves of destiny threaten to swallow him up.

The whole of this introduction sounds rather like the solemn chorus to a Greek drama, than the opening of a work on physiology, where the scene is the world, over which human beings and other living forms, interwoven like the Hours, move in endless procession, while their nature and relations are declared by one whose lips had been "touched with living coal from the altar."

The division of the animal kingdom. adopted by Treviranus, deserves attention.

"According to my view," he says, "there are two great divisions of the animal kingdom; the one consists in animals that possess a real spinal marrow enclosed in a vertebral column, which is wanting in the other class. In the first, the entire brain always lies over the mouth, enclosed in a proper bony covering, the skull. In the last there is always a ring round the mouth, formed either of one brainlike mass, or of several knots connected by nervous filaments; the brain-like substance lies partly over, partly under the last; it has no special, bony, or definal reason, which can horny capsule by which it is separated from the other internal parts of the head, and no

e nosterier part which process goes. the spinal marrow of can be compa mimals. This agrees with Lamark's division into vertebrate and invertebrate animals. They may be denominated animals with skulls, and animals without skulls.

" In all vertebrate animals, the anterior postion of the spinal marrow enclosed in the skull - the medulla oblongata - is of the same form as in man, and, in comparison with the brain, diminishes from man to the lowest degrees of this series of animals, in mass and in volume. According to the mimerical differences of this relation, four classes of these animals may be distinguished. I found the limits of the relative weight of the medulla oblongata and the brain, to be. -

In the	1st Class	between	1	:	85.0	and	1	:	6,5
	2nd ditto		1	:	24.3	and	1	:	6.7
	3rd ditto		1	:	3 6	and	1	:	3.2
	4th ditto		1		3.5	and	1	į	1.0

"On the other hand the lower animals possess, by virtue of their vital tenacity, the power, already mentioned, of absorbing more exygen, from a given amount of atmospheric air in which they are enclosed, than the higher animals, who die long before they have consumed the same amount of oxygen. The energy of their respiration is, at the same time, entirely dependent on the exist.

"The relation of the greatest diameter of the medulla oblongata, to the greatest di- lowing is a copy) from Dr. Stewart, prinameter of the brain, extends,

ln	the	1st Class from	1:6.85	to	1	:	1.20
		2nd ditto	1:445	to	1	:	1.1:
		3rd ditto	1:2.55	to	ı	:	1.57
		4th ditto	1 - 144	to	1		1 95

The first class embraces mammalia, including man; the second, birds; the third, amphibious animals; and the fourth, fishes.

The table at page 456 presents the results of his own, and of all other researches, on the respiration of animals, calculated on the supposition that the English is to the Parisian inch, as 0.938 to 1; that the temperature of the inspired air is 71%; the barometer at 30 carbonic acid = 1 per cent.

Treviranus gives a new, and certainly the only accurate method, for determining the He observes .-

restable organization, there be a higher larger degree of respiration. But there

atmospheric air is employed, and more carbonic acid is excreted. The mammalia, and birds in a perfect state, withdraw more oxygen from the atmosphere than amphibia and fishes in similar circumstances; birds more than mammalia; animals of aerial respiration more than those which live under water; many insects not only more than the molbiscæ and worms, but also than many amphibia, and when the temperature of the air is high, and they are in active movement, more than even mammalia and birds; an animal in the full bloom of age, more than the new-born, and the latter more than the embryo."

These researches are of the highest importance, and this is the only method of determining the relative intensity of respiration in different animals in different states of activity.

PHRENOLOGICAL SOCIETY OF LONDON.

SKILLS FROM THE MAURITIUS. - TESTS FOR PHRENOLOGY.

This Society recommenced its meetings for the season on Monday, the 2nd of November. Dr. Elliorson, the president, in temperature of the medium in which they the chair. At the preceding meeting the president had read a letter from Sir James M Grigor, inclosing one (of which the folcipal medical officer of the army in the Manritius: -

" Medical Department, Mauritius, Dec. 27, 1834

" Sir,-I am commissioned to forward to England, and to your care, the skulls of four human subjects, which are considered of sufficient interest to claim the attention of all lovers of phrenological science. This I am directed to do upon condition that they shall be presented to the Phrenological Society of London, upon an engagement to furnish a copy of the result of their examination. Should they decline agreeing to this condition, it is requested that they may be forwarded to the cultivators of the same inches; and oxygen in the atmosphere =21; seience in Edinburgh, and with the like injunction. The enclosed scaled packet contains matter relating to these skulls. This packet is to be retained in your possession unopened, until the report of the proportional force of respiration in animals. Society to which they are presented shall have been received; it is then to be opened, "We have yet no experiments by which it and the contents to be at your disposa, the can be determined, if, in the various stages observations of the Society, or a certified copy thereof, to be transmitted hither for the information of all concerned in this island. the facts which show, that in the The heads are numbered, and the remarks upon them, contained in the enclosed packet, bear corresponding numbers. With the as-

The foregoing account of the developments of religion. He confes of these skulls having been transmitted to kill, but maintained to Sir James M'Grigor, the packet mentioned innocent of the murder. in Dr. Stewart's letter was transmitted to the Society, containing accounts of the characters of two of the individuals to whom the skulls had belonged; these characters having been furnished by the Chief Judge of the Mauritius, Edward Blackburn, Esq. a zealous phrenologist. Upon the characters of the other two individuals it appears that no particular observations had been made. The following were the details of the names and occupations of Nos. 1 and 3; and the same with the addition of the characters of Nos. 2 and 4 :-

(

No. 1. The skull of Parillon, a native of Mozambique; a Government apprentice; and who died of phthisis on the 1st of Dec.,

No. 2. The skull of Pierre Gaya, or the Stutterer. This man, a negro slave, was tried on the charge of having murdered one of his comrades, and tried and convicted of a barbarous attempt to murder another, a female, upon the very slight provocation of accusing him of having stolen a pair of scissors. The latter crime was brought fully home to him, and the proof of fracturing his skull. He escaped on the the former only failed because the body of trial through an informality. He was afterthe deceased was never found, though dili- wards convicted and executed for a murder, gent search was made on the spot where supposed to be committed in revenge for an Pierre once declared that he had cast it; a moult offered to the family of the culprit, declaration which he afterwards retracted; who was of a high caste. His behavior im-and which, from its having been made under mediately after condemnation was brutally coercion, could not be admitted as full legal | savage, but heafterwards became more quiet, evidence. It is supposed that the budy was and died courageously. He seemed irritated curried into the sea by a flood. The description at his seatence, because no one saw him tion given of his character by his master and commit the act. He endeavoured to escape, other witnesses, his companions, and as it and severely stabled two persons who were was illustrated by examples which they i employed to take him. quoted, went to show that he was a man of | It thus appears, as Dr. Elliotson stated, great desterity in all matters of handicraft, that there were two skulls of ordinary and a clever and skilful workman, but of persons, and two of very depraved persons, desaltory and roving habits; that he was sly and cunning, and constantly stealing from his companions; that he was extraordinarily jealous, and while under the influence of jealousy, quickly rendered ferociously irritable, most abusive in language, and violent in acts. The attack on his first victim was caused by slight attentions shown to his comrade, by his master, for good conduct. He was most libidinous in tempera- cated each the character that was given of ment; two examples of the disposition are the other, in the MS., hy which they were striking. He made indecent propositions to a person in a class very highly above there was no possibility of mistaking the him; and only a few hours before his execution, on being kindly asked by his spi- being true, he had no doubt that the skull ritual attendant whether he wished to have marked 4 should have been marked 3, age any thing, he answered "Yes, a woman." any thing, he answered "105, a woman. that skull 3 should have been maked by His intrepidity amounted nearly to insensible. He added that he had written to the Man. hey at the place of execution; he mounted the ritius to this effect, confident that scaffold holdly, examined the axe, talked be discovered, either that a min freely to the executioner, and laid his head been made there, or the on the block without a sign of fear. Yet wrongly marked, it w he seemed to be impressed with some sense test phrenology. A

ittempt to that he was pected that he imagined, that as death had not ensued in the former case, he had a chance of escape if he could remove the impression of his guilt in the latter. On the plantation he was strongly suspected of frequently firing the sugar canes and buildings; certain it was, that from the time he was imprisoned to the present period, the burnings have ceased. He willed some money, which he had concealed in the ground, to one of his relations.

No. 3 is the skull of Jean Malay, or Malgachi, a slave who died of atrophy on the 1st of December, 1834.

No. 4 is the skull of Rhugoburg-Sing, an Indian, who was convicted in India of killing one man and wounding two others, under circumstances unknown to the writer of this note. He was transported to Mauritius, and was for some years employed there as a convict. He was violently ferocious, and had a strong propensity to destroy. Sometime back he was tried, for having, almost without provocation, knocked down two men with a staff, nearly killing one of them by

and that the phrenological characters perfeetly agreed with the biographical; the two former having probably been sent merely to occasion difficulty and put phrenology to a severer test.

While, however, one ordinary skull and one bad skull answered to the characters respectively given of them in the MS., it is remarkable that the other two skulls indiaccompanied. Dr. Elliotson remarked that character of the skulls, and that, phrenology that skull 3 should have been make.

LONDO

Monday, Dec. 7, 1835.

Dr. WHITING, President.

PLAN OF TREATING PRACTURES ADVO-CATED BY MR. RADLEY.

Ma. DENDY laid before the Society this evening, a specimen of badly united fracture, occurring below the cervix femoris; the head of the femur appearing to be almost twisted round, probably from the action of the muscles, so as to require some care in deciding from which side of the body the fractured bone was removed. The accident had occurred to a lady aged sixty-five years, from falling down six or seven stairs. A surgeon was immediately sent for, but he failed in detecting the exact nature of the injury, supposing, as no crepitus could be fractured. She was put to bed, and nature was left to accomplish the cure, the attendsuch accidents. This was what he Mr. D. would call, following Mr. Radley's plan of freely upon it. He considered that Mr. tageous method. Radley had only given an ex-parte statement. they gave pain; but this was reasoning from the abuse, and not from the use of splints; he (Mr. D.) had seen cases, and so must every practical surgeon, in which splints often relieved pain. And how? Why, by preventing spasms: and he was convinced that many cases occurred, in which the attempt to procure union without the aid of splints, would result in deformity of the limbs, and uselessness of those parts, as i in the specimen now before the Society, where, although union had taken place, full three inches were taken from the stature of the patient, who was crippled for life. The surgeon had failed to detect crepitus, because some portion of synovia interposed between the fractured extremities of the bone.

Mr. BRYANT thought that as the fracture was below the trochauter minor, the action of the muscles contributing to the badness of the union, this case was not a fair one to forward against the plan of treatment by Mr. Radley, who spoke not of

ment generally in the terms he had cmployed.

A GENTLEMAN observed, that Mr. Radley did not mention any cases of fracture about the neck of the thigh-bone, and thought that his plan was a good one, as Mr. Radley had lost only two cases out of a considerable number thus treated, and those would have been incurable under any treatment. Nor did Mr. Radley object to the use of splints, simply because they produced pain, but rather because, when they were dispensed with, leeches and the local applications could be most beneficially employed, and this he believed was the chief source of benefit derivable from Mr. Radley's plan of treatment. It was useless, perhaps, to omit the use of splints, if the other treatment were not employed.

Mr. CLIPTON believed that every new plan of treatment should be cautiously received, especially if the future welfare of the patient was likely to be affected if it did not succeed. In fractures, to bring and mainheard, that the neck of the hone might be tain the disunited hones in close apposition with little pain, was the object to be sought, but how this was to be effected by the simant stating his inability to afford help in ple use of pillows, he knew not. In the majority of cases the simple position would not do this; and without splints, ligamenttreatment, the doing nothing at all, and our union would result. If the splints were thus, by the specimen showed, doing worse properly adjusted, leeches and lotions might than nothing. Mr. Radley had put forth readily be applied; but on the whole, in his plan in so decided a manner, that he fractures of the lower extremities, he thought (Mr. D.) thought it justifiable to comment the double-inclined plane the most advan-

Mr. Hooven agreed with Mr. Dendy, that and, therefore, one that was not to be noticed splints rather prevented pain than caused it. and acted on. Mr. Radley objected to in a case of fracture of the tibia and fibula. splints in every case, because, as one reason, in which he had removed the splints, he found on the following morning that the woman herself had reapplied them, because she did not suffer when they were on, while without them the pain was considerable. He (Mr. H. was also quite satisfied that it was impossible to keep the fractured portions in apposition without splints.

Mr. ROBARTS mentioned a case of fracture of the tibia and fibula in both legs, that would set the question at rest. It first came under the treatment of a dresser at St. Burtholomen's Hospital, and fell under his (Mr. Roberts's) observation, producing at the time considerable impression on his mind, as to the great utility of splints in fractures. When the accident was admitted, great inflammation and tumefaction prevailed, and leeches were ordered. Excessive pain, however, continued, and was not relieved until the following morning, when one of the surgeons of the institution recommended the limb to be put into splints. Half an hour afterwards the pain was entirely gone : pretty tight pressure being used!

Mr. Criss regarded the last case as not bearing on the question at all. Would Mr. Robarts adopt the same kind of treatment

in all cases of fracture? He must confess | connection did exist | that he could not tell how pain, inflammation, and tumefaction, were to be relieved

by pressure.

Mr. DENDY wished that Mr. Radley's and for preventing the fractured extremities mercury, which might be relied on. wards attended the use of Mr. Amesbury's Mr. DENUY believed that rheumatism apparatus.

ley's plan of treatment was recommended, the muscles. nothing of fractures if it were true that all this form of disease, ends of fractured bones could be kept in Mr. Robarts be apposition only by splints and tight bandnges.

Mr. CRISP recommended that Mr. Radley's plan should be tried before it was condemned; for he had observed, and many others must have seen cases in hospitals, which would have done as well, if not better, without the confinement of splints, than

they did with them.

CONORRHOLAL RHEUMATISM.

Mr Hughes, after a closing word on the subject of fractures, requested the members' opinion respecting rheumatism when occurring in conjunction with generahea. He had lately had under his care an unusually obstinate case, inducing him to think that the two diseases might be peculiarly complicated one with the other. His patient first had gonorrhoea, and on exposure to cold an acute attack of rheumatism supervened, affecting the shoulders, the knees, and the muscles of the back, but most severely affecting the small joints of the feet. He treated it as rheumatic gout, with colchicum and small doses of mercury. Auother surgeon, however, was consulted, who immediately designated it as a case of gonorrhosal rheumatism, and ordered the patient to drink porter and take sarsaparilla, and apply iodine to the feet, but as yet without benefit. The rheumatism followed about a week after the appearance of the gonorrhoea, and the two had now been under medical treatment for nearly two months.

Mr. Pinchen said that he had met with so many cases of rheumatism occurring in conjunction with gonorrheen, that he had not the least hesitation in affirming that a and an enema syria

e two dis enses, hat what was the nection he was incapable f that conointing out, though he had observed it to manifest itself mostly in the joints of the lower extremiplan might ultimately be found to succeed. ties Bleeding and parging, as in common An apology was perhaps due to Mr. Radley inflammation, were the frequency be mostly from him, for speaking sharply of his pro-resorted to, calling in the aid of colchicum, posals, and now therefore he begged to offer but small doses of opium, as in the form of one. However splints might prevent pain, the Dover's powder, he had found exceedhe would answer for their preventing spasm, ingly beneficial. When these failed be gave of bones from grating the one over the other. answer to several queries he replied that he Mr. Dendy then related two cases, which in had frequently seen the disease prevailing the first instance were treated without in summer, and had found the patient resplints, and in which perfect success after-! cover without the aid of specific medicines.

prevailed at present very generally, but the Mr. Bryant observed that the more he disease assumed a neuralgic type. He said on the subject of fractures, the more begged to ask whether colchicum had been Mr. Dendy misunderstood him, and this found so effectual when it attacked the arose from Mr. Dendy's not bearing in mind 'neurilema or the substance of the nerves, as the seat of the fracture in which Mr. Rad | when it seized on the fascize and tendons of For his own part, he had He (Mr. Bryant) must confess that he knew found it quite an indifferent remedy under

Mr. Robarts believed that gonorrheal rheumatism, as it was termed, was confined to the joints. He had found an ointment composed of equal parts of strong mercurial ointment, and the ointment of spermaceti (aa. 388), and camphor (5j), the most effectual in protracted cases.

Mr HEADLAND did not doubt that a perfeet form of rhenmatism existed, induced by gonorrhora. He had a patient who never suffered from an attack of the one without experiencing the other, following each other apparently as a necessary consequence. There was this phenomenon attending such cases, that the swelling of the joints was less, in proportion to the pain that existed, when the attack was one of ordinary rhenmatism. He had not found colchicum under these circumstances an effectual remedy, but caloniel and opium had proved invaluable in his practice.

The PRESIDENT said he believed that rheumatism following gonorrhum, was totally distinct from any other species of theumatism, and that it certainly was a specific disease, requiring a specific remedy. Colchicum only afforded relief by lowering the circulation in the treatment of rhenmatism; he would say, that for muscular rheumatism colchicum was the best remedy; in neuralgie rhemnatism the antiphlogistic treatment was demanded; and in gonorrhoal rheamatism, or that form which affected the joints, he considered calomel and opium to be the most effectual remedy. So fully be the most effectual remedy. satisfied was be of the great efficiency of colchicum in muscular rheumatiem, did not fear to say that ninetelin of twenty would yield to the

Dr. Appraga President.

ECZEMA.

MR. HALE THOMPSON exhibited some specimens of cuticle exfoliated from the hand, so entire as to bear an analogy to a kid-glove. The patient was affected with eczema. The man was a carpenter, aged twenty four, pale, tall, and deeply marked with cicatrices of small-pox. He was admitted into the Westminster Hospital, 17th November 1835. The surface of the body in various places exhibits the cuticle in a state of desquamation, especially the thighs, the nammillæ, and the soles of the feet. The palmar surfaces of the hands and fingers have only recently parted with their enticle, and are extremely red and tender. The years ago he had small-pox very severely not add to the sensible properties of the after vaccination. He remained well for materials, combined with the liquor potasse, four years, when an eruption of vesicles which gave to the mixture a putty-like subguments being of a deep red; the red rash to Mr. Morson of Southampton-street. preceded the vesicles by a day or two, with preceded the vesicles by a day or two, with severe pain, heat, pricking, and itching; the of quinine were decomposed by the presence in a mixed desquamation of the cuticle, magnesia. With the local disease, there was consider- Dr. Johnson said he was not in the habit after, a second attack, precisely similar to therefore could not speak as to the result, the first, appeared; and searcely six months had clapsed, when symptoms of a third attack manifested themselves, followed by a general feeling of coldness. The man state.

time, as the symptoms were not ameliorated, he was ordered to return to the previous forms of medicines. The patient had not at either attack shed the nails, but they presented three distinct marks, showing thereby the degrees of growth during each attack; nor had the whole of the hair fallen off, but it was covered with an abundant scurf, and emitted a peculiar odour. The desquamation commenced where the vesicles were first observed, viz. at the upper part of the back, and about the axilla. He (Mr. T.) regarded the novelty of the case to consist in the periodical form it assumed, and he concluded by asking, whether this was a case of

The PRESIDENT believed that the case presented no new phenomenon, but would be found to coincide with the description given by Willan and Bateman.

Some discussion ensued respecting the vesicles in eczema, which the President said might be so small, that unless circumspectly observed, they might be overlooked.

Some remarks were also made on the comgeneral health is good, but anscultation de- bination of alkalies with quinine, which, tected an increase of the heart's action. Six however desirable, Dr. Jounson said would appeared over the body, of the size of pins' stance that fell to the bottom of the vessel. heads, the intermediate portion of the inte- For a knowledge of this fact he was indebted

The fourth case was as follows: on the same ground that Mr. Stafford would

The President inculcated the necessity itree of silver were applied, and he was if free and early incisions to prevent the ill consequences of tension of the parts. He a spirk aperient. Under this treatment remothered the case of a pupil, where the symptoms were so terrific, that no hope for a moment was entertained of his recovery, the consequences of the case of a pupil, where the symptoms were so terrific, that no hope for a moment was entertained of his recovery, the consequences of the case of a pupil where the symptoms were so terrific, that no hope for a moment was entertained of his recovery, the consequences of the case of the case of the consequences. d being that period. The feebled, that the loss of the smallest quand constitution symptoms were then tity of blood would probably have sunk him.

He requested Mr. Lawrence to see him, and Mr. L. sanctioned (before he, Mr. L., taught the advantages of incisions) the opening of a tumour which had formed in the side. as the pain increased. One hour after, it was found that an alarming hemorrhage had occurred from the wound, of not less than thirty ounces, after which the pulse rose, and became fuller, and, contrary to the opinion formed from the debility present, the patient progressively recovered. Where the inflammation proceeded from the absorbents, and was characterized by red lines. he advised the free use of the nitrate of eilvor

Dr. LEE observed, that when no external traces of inflammation, or other symptoms, appeared to account for death, he believed the fatal event would be found to have ensued from the inflammation attacking the dccp-seated veins.

Dr. Elliotson related three cases to illustrate amongst other positions that matter could be absorbed in dissection, withit appeared, that the finger had simply been rubbed down an arm in a gangrenous state, when dry vesicles appeared on the patient's finger, unattended with inflammation, followed by pain and tumefaction of the side, which was opened without matter appearing. A remarkable phenomenon presented when the body was examined; all the visceræ were so soft, that the finger could be passed into their substance with the greatest facility. In the other two cases, dry vesicles also appeared under similar circumstances. The patient was of an exceedingly nervous temperament, and the symptoms were regarded at first as of a rheumatic nature, but shortly after, sharp lancinating pains occurred in the side, followed by swelling. The nitrate of silver was applied, and the redness disappeared, but matter formed, unattended with any further inconvenience; no other local symptoms appeared where the eruption occurred. But the same accident occurring to him (Dr. E.), the poison being imbibed from a similar source, and in the same manner, only slight local symptoms followed, unaccompanied by any constitutional derangement, in consequence of his being of a robust constitution, but the pimple remained for full two months. He concluded, from the facts he had observed, that the symptoms which follow, whether local or consti tutional, or both combined, do not result from the application of the poison to particular parts or structures, but rather depend on the peculiar nature of the constitution of the person infected.

The meeting then adjourned.

AT TUNBRIDGE WELLS,

TO DISCUSS THE OPERATION OF THE

POOR-LAW MEDICAL CONTRACTS.

AT a meeting of the Medical General Practitioners residing at and in the neighbourhood of Tunbridge Wells, held in that town on the 24th Sept. 1835, for the purpose of considering the effect of certain clauses in the Poor-Law Amendment Act, on their interests, and the welfare of the sick poor,

It was resolved, -That while this meeting disclaims any factions reposition to the new Poor law Commissioners, they feel it right to form a Committee for the purpose of watching the operations of the Paor-Law Amendment Act on medical interests, and that Messrs. West, Starling, and Way, be appointed such comm'tee, the members of this meeting, at the out an abrasion of the surface. In one case | sme time, pledging themselves individually not to enter into any contract for the whole, or any district of a union, with the guardians of the pour, excepting with the concurrence of the above-named Committee. The above resolutions were then signed in form by the members present, who consisted of the following gentlement :-

Isaac Haegraves. William J. West. William Wallis. Robert J. Starling Christopher Pentold. David Henry. W. Way William Wieden.

Peter Brown. John Sloane. Charles Trustram. E. H. Finley. Robert Gibbon. John Outtoridge. Jonathan Monckton. Stephen Monrkton. JAMES CORNWALL, Chairman.

Shortly after this meeting, the Assistant-Commissioner, Sir F. Head, and the Board of Guardians, gave notice to the medical gentlemen of the district, that they had decided on allowing 250%, per annum as the salary for attendance on ten parishes, comprising a large and widely scattered population, the former salary for the same attend-ance having been 470%. On the receipt of this communication a second meeting was called. and held on the 11th Nov. 1835, when

It was resideed,-13). That a communication having been received from the guardians of the poor of the Tunbilige Union, stating that they had appear tioned the sum of 252/, per annum for the whole medical and surgical attendance (excepting midwifers) in such Union, this meeting laments the prartice which has been adopted in other unions of obtaining medical efficers for the poor by threats, beld out to compel them to take the contracts on the appressive " d inadequate terms which had been proposed, and that they consider such a course as degrading to the m fersion and injurious to the pauper poor gent cases involving life), and that we for providing " efficient mention ance on the poor," easing 2nd. That trusting w

EDICAL DEPUTATION.

Of Consideration (men, capable of ervices, and the fat to meet them on something like fair and adequate terms.

3rd. That a Committee, conflicting of the four following gentlemen. be deputed to wait on the Board of Guardians at their next meeting, to present and supportake resolutions of this meeting. Mr. Monckton, sen. (or jun.), Mr. Cornwall, Mr. West, and the chairman of this meeting, or such other gentlemen of the present meeting as they may depute.

(Signet) ISAAC HARGRAVES, Chairman,

The above-named gentlemen (Mr. Way, in Mr. Cornwall's absence, taking his place) waited on the Board of Guardians, when the Chairman, Mr. HARGRAVES, read and presented a copy of the resolutions, and stated that he was instructed to urge on the consideration of the Board, that the medical men were badly paid at their former salaries, so that the offer now made, of little more than half that amount, was unjust to the pour, as well as to the profession. He re-showed, on the part of the medical men, quested also to be informed what the precise daties of the medical men would be.

Mr. Hargraves was here interrupted by Sir F. HEAR, who said that he would not give the least information to parties who on which the Board were proposing to act, came as the deputation had done; that the language of the former resolutions, as well as of the present, was highly improper to be used to him, and that it was evident the deputation bad come for the purpose of insulting and abusing him, and that such conduct -

could not be tolerated.

The CHAIRMAN of the deputation immediarely disclaimed the most distant intention of offending, much less of insulting, Sir F. Head, and the Board of Guardians, and though he still contended that the language complained of was that of truth, he would, in accordance with the feeling of the Board, and at the suggestion of an influential member of it, withdraw the objectionable words "threats held out" and "oppressive."

This proceeding was satisfactory to all parties but Sir F Head, who resumed his vituperative and insulting strain of language, endeavouring to impress on the Guardians and the deputation, that their language in addressing him was highly un-

becoming and improper.

The CHAIRMAN of the deputation upon this appealed to the Board to say, whether, having, in compliance with their wish, withdrawn the offensive words, Sir F. Head was justified in thus treating the deputation, and he (the Chairman) would now individually tell Sir F. Head, that he (Sir F. H.) back he right to speak as he had spoken, and that be (Mr. Hargraves) cared not, after his ent of the deputation, whether he felt er not. The Chairman was here but on again resuming he the assertion that out "to the medical

prable men, by quoting the words of Sir F. Head exame of Medical at Tunbridge, to the effect, that if the mee sick phor, we hope dical men of the Unions would not take the contracts on his terms (at the same time boasting that he had reduced them nearly, or quite, half), competent men from London would be brought down, who would gladly accept them for the advantage of an introduction to private practice.

Sir F. HEAD admitted that such had been his words, and angrily added that he would

repeat them.

Mr. Way next addressed a few words to the Board, and showed, by a reference to the resolution itself, that it could not be meant that that Board had used "threats," or were treating the medical men oppressively, but that on the contrary, they were hoping to meet them on fair and honourable terms. Mr. Way begged to ask the Board on what calculation or data they had fixed the salary of the medical officers, and, from a statement produced to the Board, he that the average remuneration of his own services in one parish, was only one penny for each patient actually attended, including medicines. He objected also to the principle as pressing most unfairly on one class; and observed that on such a principle, it would not be difficult, without for an instant impagning the ability of Sir F. Head to execute the duties entrusted to him, to find numberless individuals, equally qualified, who would gladly take his situation, with half the emolument.

Sir F. HEAD, in reply, acknowledged that the compensation was inadequale, and further observed that the principle upon which he had invariably acted was to give the preference, in the appointments, to those gentlemen who were already in possession of the parishes; and that notwithstanding what had passed, the same principle would, in the PRESENT INSTANCE, be adopted.

16th Nov. 1835, at an adjourned meeting, Ac. Ac.,

It was resolved,-1st. That this meeting receive with much concern the communication from their denutation, of the refusal on the part of the Assistant-Commissioner and Board of Guardians to after their decision as to the amount of salary to be given to the medical officers of this Union, and do express their deep sense of the injustice of such determination, as affecting the interests of the poor, as well as the medical profession in general.

2nd. That this meeting concurs in the expedience of accepting the terms named by the Board of Gaardians.

3rd. That Mr. West be requested to confirm the contract in behalf of the meeting for Tunbridge Town District, Mr. Monckton for that of Brenchley, and Mr. Way for that of Tunbridge Wells, and that in case of any difference of opinion, or difficulty arising, in defining the limits, or appropriating the portions of daty or salary, Messrs. Prince, Hargraves, and Cornwall, he appointed as referees, and their decision to be considered final.

4th. That on entering into the necessary contract with the Board of Gaardians, this meeting do request the gentlemen so contracting, to present a protest against the conduct pursued towards them, whereby they have been compelled to undertake duties, without anything like an adequate remuneration.

5th. That the following be the form of such protest :- " This meeting most respectfully, yet most firmly, protest against the conduct which has been pursued towards them by the Assistant-Commissioner and Board of Guardians, by which they have been compelled to accept of terms for their professional services, which they feel to be degrading to themselves. They have asked for, and have been denied, information as to the grounds upon which the Board have decided on the amount of their salaries. They have presented to the notice of the Board a statement of their past services and remuneration, and it has been admitted by the Assistant Commissioner that an adequate compensation was not allowed. It has been avowed that upon their refusal to accede to the proposed terms, strangers would be introduced into the districts, to the manifest injury of the present medical practitioners. Such avowal must be deemed as a threat to those whose interests are so intimately ; concerned thereby. They consider, also, that the sum proposed has been determined upon, without due regard to the required duties, and at variance with the remuneration allowed in other Unions. Under these circumstances, this meeting feels justified in declaring, that the manner in which its members have been treated has been unjust, arbitrary, and oppressive, and such as could not have been contemplated by a wise legislature."

(Signed on behalf of the meeting.)

On the day appointed by the Board of Gnardians, Messrs. West, Monckton, and Way, attended the meeting. There was also in attendance (but of course not with the deputation) an individual who, alone of all the practitioners in the district, had from the first declined acting with his professional brethren. The names of the members of the deputation were sent in, with a statement that they were waiting for an interview, and after some little time, Mr. Monckton was called before the Board, when the Chairman announced to him that he had been unanimously appointed to one of the districts, upon which Mr. Monekton replied that he thanked them for their unanimity, but could not thank them for the appoint-Mr. West was then appointed to another district, and in reply Mr. West said that he felt the appointment was forced upon him, and that he would give any one twenty guineas above the salary to perform the services. Immediately after this to the great surprise of the deputation, the indivillual above alluded to as not forming part of the deputation, was appointed to the remaining district without the least explanation on the part of the Board, or even the slightest notice of what had been done being made to the deputation!

25th Nov. 1835. - A gourned mecing, Se. Sc.

It was resolved, -14. That this meeting capro their deep sense of the apparent injustice which the Board of Guardians of the Tanbridge Union have committed, in appointing a gentleman who has been less than four months in the district, to the charge of the sick poor of four parishes, which have higherto, for many years, had the attention of five of the oldest practitioners of the place and neighbourhood, who were willing, if required, to continue their services for such purpose, on the proposed terms. This meeting feels, that such appointment has been made in violation of the principle and the public pledge of the Assistant-Commissioner himself,-pamely, " that those who already had the attendance of the parishes, should have the preference given them in the new arrangement." In the absence of all explanation from the Board of Guardians, the meeting is compelled to conclude that the appointment has been made, they will not say in a spirit of vindictiveness or resentment, because its members have dared to remonstrate against grievances imposed on them, but certainly without due consideration.

2nd. That the Chairman, with Mesars. Cornwall and Way, be requested to form a committee, to give publicity to the proceedings of this and former meettures, as they may think proper.

3rd. That this needing be formed into an association, and that it be called "The Medical Association of the Tanbridge Union."

Signed on behalf of the meeting, J. HARGRAVIS, Chairman.

A Copy of the above was then directed to be forwarded to the Board of Guardians, to be laid before them at their next meeting.

THE LANCET.

London, Saturday, December 19, 1835.

The proposal for establishing a national University in this metropolis, is exciting very general attention, and there are few persons to be found, even in the ranks of the bigots, who offer any serious opposition to the scheme, as it has been propounded by the friends of the Ministers. The founding of the Institution, therefore, is regarded as a matter of certainty, and the public have only now to consider on what terms, or "conditions precedent," the degrees or honours of the University are to be a what the lies are injurious to community, we are

ciples which con the unqualified sanction, not only of the well-informed people of this country, but of all the enlightened men of Europe. Assuredly. therefore, it cannot command so great an extent of admiration and respect, if the CHARTER OF INCORPORATION give to the conductors the power of raising up obstacles, in the form of CURRICULA, which shall prevent all persons, excepting the students of a few favoured institutions, from being received as the legitimate candidates for degrees. Such obstacles would create another monopoly of a scarcely less objectionable character than that of Oxford and Cambridge. The principles of government, in order to be just, must be simple; but there is neither justice nor simplicity in withholding from genius and talent their full share of honourable reward. The production of "certificates of attendance," too often given by the professor in the absence of any personal knowledge of the student, cannot increase the acquirements of the candidates, either in number or utility. If the great scholastic institutions which this charter, it is supposed, is designed especially to favour, do not dread a competition with the private, less ostentatious, more retired establishments, in many of which are taught the higher branches of knowledge, how can the conductors and supporters of the former honestly and reputably contend that all students ought not to be placed upon an exactly equal footing in the Examination Hall of the new University? If distinctions be made, if exceptions be introduced, they must operate as unjustly in London as they have already operated in Oxford and Cambridge. If it be not the object to confer honour upon the acquirements of genius, let an acknowledgment to hat effect be made at once; and if it be the intention to confer titles in learnnd science, as a species of reimbursement diture of so much money under het-and-certificate eye

London, upon prin- | fem, then, also, let that intention be honestly confessed. If the exceptions to which we have here briefly adverted, be actually made in the new charter, the public will naturally and correctly conclude, that there exists a desire, from some motive or other, to give an artificial value to the education of persons who are instructed in particular establishments. Such a proceeding is not fair. It is infinitely beneath the object of a great and liberal government, and the scheme would no sooner be in operation than it would be productive of very general dissatisfaction; the honours which it would be designed to confer, would carry with them no weight or importance among the enlightened portion of the community. We refrain, however, from now offering another word on the subject, in the hope that the advisers of the Crown will take the earliest possible opportunity of publishing a draft of the charter which it is their intention to frame for founding and governing the metropolitan University. When this document is before the public, then, and not until then, shall we be placed in a position to object, by petition and remonstrance, to the obnoxious clauses, if there be any such, in the new roval instrument.

> THE following note accompanied the communication which will be found at page 466 of the present Number of our Journal:—

> > To the Editor of THE LANCET.

Sir.—As secretary (pro tempore) of "The Medical Association of the Tunbridge Union," I am requested to forward for your information, and, should you think proper, for publication also, the minutes of the proceedings of our different meetings.

I have endeavoured to give you all the facts connected with them as concisely as possible, and our object in senting them is, through your means, to invite our professional brethren to form local associations, to terminate in those of the county, and under the idea that one or two gentlemen from each county might unite to form a deputation to his Majesty's Ministers, for the purpose of obtaining redress of the grievance, I am, Sir, your obedient servant, W. Wax.

Tunbridge Wells, Dec 1, 1835.

In placing this note before our readers we may state, that although we approve of the purpose therein mentioned, we consider that if medical gentlemen would but combine to suggest a plan for amending the state of the law with regard to the treatment of the sick poor in the new parochial unions, it would be infinitely preferable to making any application to the Ministers on the subject. It is not right either that the sick poor of this kingdom, or the surgeons of England, should be left to the mere mercy station, their respectability, or the benevo- is taken from the Courier of Dec. 12 :-lence of their intentions. Experience has It is the law, therefore, that must be made the members of the Legislature will be very hearty in their condemnation of the proceedings of the Poor-Law Commissioners, or their assistants, unless medical gentlemen can themselves point out what ought to be observed in making the contracts between attendants. We hope, therefore, should deputies from the county associations assemble in London, that they will visit the metropolis fully instructed by their constituents as to the plan for which the medical practitioners of England would be anxious to obtain the sanction of the Legislature. It is quite evident that there must be some definite settlement of the question out of doors before it can be brought forward again within the walls of Parliament.

The insertion of the communications of Mr. WAY would have taken place last week had not a want of space rendered their publication at that time impossible. The statements contained in the reports are calculated to excite the utmost feelings of indignation against the authors of the insults offered to the deputation, in the mind of every man of correct gentlemanly feelings who peruses them. .

the University of Edinburgh, ted by the death of Professor TURNER, has been conferred in a very honourable and flattering manner on our distinguished anatomist and physiologist, Sir CHARLES BRLL. The only thing we have to regret in making this announcement is, that the emoluments of the office are not commensurate with the value of those services which Sir CHARLES BELL has already conferred on mankind. The followof any set of men, whatever may be their ing paragraph relative to this appointment,

"The Refermed Town Conneil of Edinalready proved that the law is defective. hurgh have done themselves great credit hy their unanimous appointment of Sir CHARLES BELL to the important Chair of more perfect; but it cannot be expected that Surgery in the University of Edinburgh, We cannot conceive a more disinterested or praiseworthy discharge of public duty. There are at present several surgeons in Edinburgh, of distinguished ability, though unquestionably not one of them enjoys the high professional reputation which Sir C. Bell has deservedly attained, most espethe rule of law which should invariably be cially as a public teacher; but all applications for any individual excepting Mr. Liston, whose eminence as a surgeon is Boards of Guardiaus and parochial medical inniversally acknowledged, were entirely disregarded, and as soon as it was ascertained, by reference to Mr. Liston, who has lately settled in the metropolis, that he would not forego his prospects in London for any of the medical chairs in the University of Edinburgh, the members of the Edinburgh Council resolved, painful as it was to the feelings of some of them, not to pay the slightest attention to the private solicitation of friends, but at once to clect Sir Charles Bell, as by far the fittest individual who was willing to accept the situation, and thus to uphold the fame of the first medical school in Europe."

> Had Mr. LISTON accepted the invitation of his countrymen to return to Edinburgh, and taken the Chair of Surgery, he would have acted, we think, most injudiciously. Within the short space of time that he has already resided in the Metropolis, Mr. Lis-TON has succeeded in establishing her reputation equally well founded with that which he had previously acquired by exercise of his scientific attal Edinburgh. If he could be the to quit the Metropoliteby the offer of

of he Universit would have incarred an irreparable loss by his tecession from that establishment.

INTERCEPTED LETTER.

"DEAR DOCTOR MACMICHARL, - 1 am determined to print my last oration, as all my friends tell me that the Latinity of it is elegant, and that the whole is in good classical taste. Perhaps your friend MURRAY would publish it as a shilling pamphlet, illuminated with a view of Pall-Mall-East, as a frontispiece. I will undertake to sustain all losses in case he should fear to print it as a bookseller's speculation. It may give our sacred cause a lift, and we ought not to throw away a chance in these hours of convalsion and alarm. It will also promote friends in Lincoln's-Inn-Fields and Bridgeour interests to get it reviewed, a duty which con can desire Fengusson to perform in the they grant diplomas and licenses will of Quarterly, but pray caution him not to use course be freed by the Government from so much fulsome language-or what people, having anything more to do with the Colof good taste call flummery -us he did in lege and Hall corporations. In fact, the the review of my former orations. I require game seems to be altogether up, and what no puffing. My classical acquirements are to do and what to say I know not. It is, universally acknowledged. I desire him to indeed, most mortifying to me that I have write nothing laudatory of them, but to con-fine his critique to the scientific and high Government in their various arrangements.

Downing-street, and although at this early tampered with Sir Robert Pret and my call it, must soon burst, and therefore let us cerity, and avoid asking my counsel. hope that by early information on what the Government is contemplating, we may make my health, I must come to London at the at least some effort to parry the blow which latter end of the month. I will then make awaits our ancient and venerable institution. the necessary arrangements for getting up It appears that the 'Central Board,' the very the evening recreations at Pall-Mall East. name of which is sickening, and about which to accomplish which, however, I see many we heard so much during the Parliament- and serious difficulties. I must also call the ary inquiry, is contemplated to be formed attention of the Fellows to the sinews of in right carnest, the Government having war, a matter fraught with anxieties, as determined, to the joy I suppose of all the there have been so few monies received for liberals and radicals, to form such a Board, licenses lately. Surely A Friend of THE LANCET is mistaken. He will, however, greatly oblige us by stating, at once, in confidence, his reasons for believing that the author is Mr. R. We can show good reasons, at present, for doubting the correctness of the allegation.

Very many of the communications lately forwarded to us will be inserted. Want of space only, in appropriate parts of the Jourual, has yet kept them from publication.

A correspondent informs us "that Dr. Webster only lectures at King's College for his friend Dr. Hawkins, and until Professor Paris undertakes the duties of the chair of Mat. Med." We have not had room for the long communications from various parties who feel interested in this complicated affair of appointments and retirements and reappointments. Did Dr. J. ****** really wish his letter to be published?

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER SITY OF PARIS.

BY M. ANDRAL,

Physician in Chief to the Hopital de la Pitie, and the Principles Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculte de Médecine or Paris.

LECTURE V.

INFLAMMATION OF THE SPINAL MARROW.

Ir has long been known, gentlemen, that the contents of the vertebral canal are subject to inflammation, as well as the contents of the cranium, but it is only within latter years that the disease has been studied with great care and attention.

Inflammation of the spinal marrow, known by the name of myelite in the important work of M. OLLIVIER, may be distinguished into two forms, the acute and chronic, but instead of pursuing each of these forms separately, I shall lay before you a general idea of both together, taking care to dwell on the characteristic points that are peculiar to each.

The Anatomical Characters of Myelite.

or inflammation of the spinal marrow, are the same as in encephalitis; it is, therefore, unnecessary to recor to them here; you have the same injection and thickening of the same suppuration in the interior of both tissue, we may have a vacuum produced, organs: indeed, this is a necessary conse- or a true canal, analogous to the normal one

The same of the sa

this affection. From the united effects of ramollissement and suppuration taking place in the substance of the spinal chord, and gradually operating its destruction, we sometimes have a very remarkable circumstance produced, viz., the nearly complete separation of the spinal marrow into two distinct parts. In some cases the abscess has been found so extensive, that the superior and inferior portions of the chord were mercly held together by a few ragged shreds. Of this we have more than one example in the science.

The lesions accompanying inflammation of the spinal marrow may vary in seat, from one extremity of the chord to the other. Th myelitis may be general, or it may be par tial, and the latter form is fortunately muc more frequently observed than the former When the myelite is thus partial, it may oc cupy any portion of the chord; but it is usual to distinguish it into three principal forms, as it may affect a portion of the spinal marrow corresponding to the cervical, the dorsal, or the lumbar regions. Again, whatever part of the length of the chord may be involved in inflammation, this latter may occupy either the whole thickness of the chord, or its anterior, or finally, its posterior column only. All these subdivisions are not made for the sake of arrangement: they will present themselves to you in practice, and are of importance to be noted, because in many cases they give an explanation of the nature of the symptoms we observe.

Besides the divisions which we have just pointed out, the inflammation may engage either the white or the gray substance of the spinal marrow; the latter is much more frequently attacked than the former; and when the inflammation occupies the centre the membranes; the same induration or of the chord, giving rise to a softening of ramollissement of the nervous substance; its substance and destruction of the nervous of the chord, giving rise to a softening of quace from their identity of structure, which exists at a certain period of foetal However, diseases do not occur with the life. I had an opportunity once of seeing a frequency in the one as in the other. case of this kind in an old man: the centre of the substance of the spinal mar- of the chord contained a canal hollowed out which we have not many op-by the suppuration, and which at first sight M. Velpeau pub-might have been mistaken for a natural atriking example of cavity.

The Causes of Myelite

are the same as those of encephalitis. Inflammation of this portion of the nervous centre may equally be produced by external violence, such as blows, falls on the back, &c. It is also frequently produced by disease in the neighbouring parts, especially in the bones comprising the vertebral column. Finally, inflammation may be occasioned simply by too strong an action of the part. You know that encephalitis is sometimes occasioned by intense study, over-exercise of the intellectual faculties, violent passion, &c.; in the same way, neglect may be produced in cases where the action of the spinal marrow is carried to a high degree of intensity. Thus in animals which have been over-worked, or which are compelled to make violent and long-continued muscular efforts, M. Dupuy has found more or less trace of inflammation of the spinal chord after death.

The Symptoms of Myelite.- The division of lesions occurs according as the functions of nutrition or of relation may be deranged. In the first place we may have several of what we may term negative symptoms: the intelligence is usually intact, we do not observe delirium &c., if the inflammation occupy no other part than the spinal marrow; the patient is free from headache, giddiness, and other symptoms of cerebral irritation. We are, however, to except cases where the inflammation engages or may extend to the upper part of the coord; when the medulla oblongata becomes implicated in the disease, we may observe agitation, delirium, coma, and other phenomena, arising from the proximity of this part to the great centre of the nervous system. The derangements of mobility naturally occupy a principal part amongst the symptoms of myelitis; they are very various, and predominate over all the others. In some cases the faculty of motion is extensively compromised, and hence after death you will generally find that the inflammation occupies the anterior pillars of the spinal marrow. This pathological fact is perfectly in accordance with the physiological experiments of M. Magenbie, who as you know has proved that the anterior columns chiefly preside over the motions of the body. The seat of those lesions of mobility will depend entirely upon the part of the spinal marrow that is inflamed. Hence they vary with the divisions we have just now established, as the cervical, dorsal, or lumbar portions of the chord become implicated. The faculty of motion, then, may be lost in the superior extremities; in the trunk and muscles of respiration; in the lower extremities. All these parts may be variously affected, and perhaps the only general principle we can lay down is, that the lesion of motility affects all parts of the muscular vertebral canal is

500

system which receive their series from below the inflamed point prical prical chord.
All these part of present various lesions of motility such as convulsion,
paralysis, contraction, see; there are, however, some exceptions to the general rule
now laid down. Thus in the Physiological
Journal of M. Magradie, you will find a
very remarkable case related: the cervical
portion of the spinal marrow presented a
considerable degree of ramplissement in
its anterior columns; the upper extremities
were paralyzed, but the lower limbs preserved the faculty of motion intact. Here,
then, the influence of the disease was not
propagated downwards.

A second general principle to be deduced from the cases of myelite which we have observed ourselves, or which have been published by others, is, that when the inflammation commences in the lower portion of the chord, producing paralysis of the inferior half of the body, it has always a tendency to mount upwards; you will first observe a paralysis of the abdominal muscles: the chest next becomes affected; and, finally, the upper extremities lose their power of motion. This is a principle that you should remember, for it explains the trouble of respiration and other grave symptoms, that we often witness in the latter stages of myelitis.

We have now to inquire into the nature of those

Lesions of Motility

to which we have pointed, as the principal characteristic symptom in inflammation of the spinal chord. The muscular action may undergo various modifications, according to the seat and march of the disease, the lesions of motility being more or less marked according as the inflammation may take on an acute or a chronic form. In some patients we do not observe any true paralysis. The only modification of motility which they present is a certain weakness and loss of force in the extremities sometimes. Sometimes the paralysis attacks a single finger, then gains the rest in turn, and gradually ascends up the arm. Some patients complain of nothing but a feebleness when they would grasp any object, an incapability of executing their accustomed motions with energy. Others, again, are attacked with convulsive motions in some of the muscles. The paralysis may come on in a gradual manner, being preceded for months, even a year, by weakness in the limb; or, on the other hand, it may declare itself in a sudden and unexpected manner. This latter for is much more rare than the preceding, because chronic inflammation of the spine marrow is a disease more frequently with than acute myelitia. the existence of infla

motions assume the character of chorea, and and the only sign of lesion exists in a small portion of the canal, not discoverable unless pressure is exercised directly upon it. Sometimes the pain is singularly influenced by a des. Finally, tetanic symptoms may join change of position; there are patients to themselves to the long catalogue of lesions whom the horizontal posture is intolerable, and who cannot lie down without suffering a degree of pain which compels them constantly to observe an upright position.

Although the spinal marrow is deeply row may give rise certainly to tetanus, as it seated in the centre of a bony canal, and sometimes does to chorea; the symptoms covered with a variety of parts, such as are then terrible, and the sufferings of the bone, ligament, muscular tissue, and skin, tient only terminate by his death.

Yet experience has established beyond all thus you see how various are the lesions doubt, that during the existence of an acute

But before we go any further, let me e length of the nervous pulp, we may never affirm the chord to be inflamed from the condition of tenderness, passing into this one symptom alone; the reason is evident. Reflect for a moment on the number and variety of parts submitted to pressure, when you run your finger along the spinal column in the manner just pointed out. An

affection of any one of these tissues may length of time by acua clearly give rise to painful sensations, and limbs. To the to which we even the more readily as they are more cannot too strongly three your attention. superficial. Let us enumerate briefly these several parts. In the 1st place, commencing from within outwards, you have the fibrous tissue, and this you know is one frequently subject to rheumatic inflammations; hence the sensibility of the integuments may be nothing but a simple rheumatic pain. 2nd. Some one portion of the osseous canal may be diseased; the intervertebral cartilages may be ulcerated, the bodies of the vertebra inflamed, the spinous processes themselves more or less extensively carious. In all these cases, pressure will necessarily produce more or less pain, without the nervous pulp being at all implicated in the malady. 3rdly. The symptom in question may depend upon a true neuralgia of the spinal marrow, a disease whose existence has been established upon authorities that we cannot contest; rachialgia then may produce tenderness along the dorsal region. though it differs essentially from inflammation; indeed, the pain by which it is accounpanied is in general more severe and excruclating. Finally, the disease may be confined exclusively to the membranes of the chord, and the modification of rensibility which now occupies us, will, in that case, be connected with a lesion to which the substance of the chord itself may be a complete ; stranger.

Levions of Sensibility in more distant parts.

So much for Icsions of sensibility in the peighbourhood of the canal. In a second form we said the pains might occupy a distant portion of the body, the limbs, for example, the abdominal region, &c.; or may follow the trajects of the great nervous chord. This species of pain sometimes accompanies the disease through its whole course, and is constant; at other times it is intermitting, and does not affect the patient except at certain intervals. It plays a most important part in the history of mycmore than common attention. In more than one case these pains in the limbs have imposed upon the physician, simulating in the closest manner a rheumatic affection, or other pains, and withdrawing his mind from the real source of the disease, to search after another that has no existence. You will find several examples of this, as we may call it, false rheumstism, in authors, where certain painful affections of the limbs were for a long period of time the only remarkable symptom; and where their subsequent termination in a dangerous disease indicated, though 200 late, the origin from which they were derived.

In certain cases the development of innerrow is preceded for a very considerable a total annihilation

some of the Remember then that the principal affection may commence by sympathetic derangement of the generality in a distant part of the body; that this lesion may exist for a long period without any apparent connection with the chord; and finally, that inflam: .ation of the nervous pulp may reveal itself by no other symptom than pains, more or less acute, in some one of the four members.

Let us now turn to a contrary case, viz., one in which we have

Myelite accompanied by a Diminution of Sensibility.

not by a derangement, but by a diminution, or even a complete loss. In most examples that we meet with, the loss of sensibility is partial, commencing in a particular portion of the body, as for example, the fingers, and then gradually extending to the root of the body. But sometimes the whole surface is equally affected. We do not find any trace of sensibility on pinching the integuments all over the body. The lesion is here general; but observe a curious fact, one of those exceptional circumstances which present themselves so repeatedly in the study of nervous diseases, and which we are mable to explain upon any anatomi al principle. Even when the loss of ser it dity is, as we have raid, general-when the whole body scens equally withdrawn from external ruspressions, you will sometimes feed a few points of the fut gama ats, parhaps a single line, in which the faculty of you attour still lingers, while all around it, as it were, dead. We have witnessed more than one case of this kind. It is a curious point in the lastory of myelitis; for how can we explain the fact that out of many parts supplied by the same nerves, receiving their hervous influence from the same portion of the spinal marrow, one remains perfectly insensible, while another, distant but a few inches, or even lines, conserves its power of perception intact. In a far greater number of cases, however, the lesion of sensibility is not so extensive; it may consist in a single engourdiscement, or numbers of certain parts of the body; this is chiefly seen in cases of chronic myelste, when the nationt experiences no modification of sensibility except in the upper extremities; the fingers, perhaps, are numbed; the patient has a tingling sensation in the extremities; sometimes the whole arm is cold, or he is quable to warm bimself, and complains constantly of a sensation of chilliness.

Thus you see how inflammation spinal marrow is accompanied by symptoms of derangement motility, varying for muscular power in

Thus we part of the spinal marrow, or at least from have two species of derangement in the circulatory organs accompanying myelitis. The fact which we have now cited is a One in the acute stage, the simple inflam-

by fainting and a momentary suspension of time to attacks of dy the circulation. Let us now examine

What influence is exercised on the Respiratory Organs in Myelite.

We cannot doubt but that inflammation of the spinal marrow modifies this function in a considerable manner, especially when the inflammation occupies that portion of the chord from which the intercostal nerves are derived. When the disease is situated lower down, the patient may remain free from symptoms of dyspnæa for a length of time: this we can readily conceive; however, in almost all cases when the mulady has been prolonged to any considerable period, the respiration becomes embarrassed. and, in virtue of a law which we laid down in a previous part of the lecture, every myclite has a tendency to ascend from the lower portions of the spinal chord to the superior. In encephalitis, or inflammation of the brain, the pneumogastric nerve becomes implicated, and the respiratory functions are eventually deranged, from the trouble of innervation in the central organ of the nervous system. In myelitis, or inflammation of the spinal marrow, the circumstances are quite universal, or nervous, very cenerally asserted in anadose, influence is no longer cerebral, or nervous, very cenerally asserted in anadose, consideration of desinner resident vessels accreting the perspiration cease to the intercostal nerves; the muscles of the chest cease to act, and respiration is gradually extinguished. In some cases the diaphragm is chiefly affected. This important muscle is occasionally struck with paralysis, or ceases to act with its accustomed energy. In other cases the action of the muscles is inordinate. Finally, we sometimes have occasion to observe cases where the actions of the diaphragm instead of being performed with regularity, as in a state of health, become spasmodic, and the pa-tient is distressed with a constant hiccup.

The definitive result of the various lesions of the respiratory organs which we have just enumerated, is to produce sooner or later a degree of asphyxia, under which the greater number of individuals who die from inflammation of the spinal marrow. succumb. The influence, then, of myelitis on the respiratory functions is well established, and sometimes the first signs may be discovered long before the disease has sufficiently advanced to modify the motions of the chest. I will relate to you a case which I saw this summer :- A young man had suffered for a length of time from a fixed pain in the upper part of the cervical vertebrae: this was accompanied by a bruit de cracquement, whenever the region of the neck was ments of certain physiologic submitted to examination. During the connection between the positionance of this pain in the region of the spinal marrow and the spinal marrow, he was subject from time to reproductive propensity.

sof the most violent character, suffocation; which fid access of imminently to threaten his existence : this lasted for a few minutes and then went off, to return again at an uncertain placed. Upon examining this case with some attention, we thought the symptoms depended upon some disease situated in the articulation of the first cervical vertebra, giving rise from time to time to displacement and strong compression of the spinal marrow. You can understand that if the attacks of suffocation to which we now allude had continued during a long period, they might naturally enough have led one astray, and given rise to the idea of asthma: indeed, perhaps, we might not go too far, if we were to say, that certain species of this latter disease, which most authors regard as depending exclusively on an organic lesion of the heart or pulmonary tissues, might be traced to derangement in an organ far from either the respiratory or the circulating systems. It now remains for us to ask.

Are the Secretions modified in Myelite!

Yes, certainly, inflammation of the spinal marrow does modify them, though not in cumstances are quite different. Here the nuv remarkable degree. You will find it in a diminution or loss of the incchanneal act when the limb is paralyzed; in a word, powers which dilate the chest. The inflamed that such portions of the body as have lost portion of the chord no longer stimulates the power of motion do not perspire. This may sometimes be the case, but it is far from being a general rule. I have seen many cases which prove the contrary. There is another fluid which is modified, but merely in the mode of its exerction. Several patients affected with inflammation of the spinal marrow, cannot urinate well; however, observe that this does not depend upon any diminution or change in the secretion itself; the incapacity of prinating is here one of the phenomena of paralysis, and the secretion is retained because the bladder is unable to expel its contents. Having thus briefly noticed the modifications of secretion, we come to a question of great interest, and one which has given rise to considerable controversy, viz.,

How far are the Reproductive Organs influenced by the existence of Myelite!

Here the facts upon which we can depend are very few; however, I may tell you, that I have seen a patient affected with acute pain along the dorsal region, with pains in the limbs, convulsive movements, and other similar signs of myelite, in whom there isted at the same time a very considerable excitement of the genital organs, sugpriapism, &c., and this confirms the

chronic m has been o flammation 3 known to bring on complete impotency. The facts to which we have just now alluded, and several others that we possess, are not to be neglected because they are not, perhaps, as complete as we could have dewired: if we cannot derive from them any rigorous conclusions, they seem at all events to indicate that the spinal marrow is not derangement whatever in the organs of gestation.

The Diagnosis of Myelite.

seat, intensity, and duration of the malady. Let us then pass to the diagnosis of invelite.

On reflecting upon the numerous lesions of sensation and motion which successively present themselves during inflammation of the spinal marrow, you might think it an easy matter to form a correct diagnosis of the disease, and distinguish it from all other organic affections, but this is not the case. It is by no means easy to determine, in all cases, that the inflammation is situate in the marrow alone, or to discriminate its accompanying symptoms from certain analogous phenomena that occur in the course of other maladies. There are several circumstances which may lead you into error; let us hasten to point out the leading ones. In the first place, the osseous tissue composing bodies of the vertebree may be the part

The training of the second

an exactly opposite state whether the early symptoms depend on a true inflammation of the nervous pulp of the chord, has here been chord, or on a similar affection seated in the bony canal surrounding it.

There are cases where the phenomena of inflammation of the spinal chord are belied, if we may use the term, by other maladies of a different nature, where the functions of this part of the nervous system are notably deranged, without any trace of organic change existing after death. This is a fact altogether foreign to the normal accom- upon which you may rely with certainty. I plishment of copulation. In the female sex have seen many examples of it myself, and we also observe a certain number of facts therefore speak with more confidence than that are worthy of attention. Thus authors if my assertions were founded upon the tes-relate that acute inflammation of the spinal timony of others. I have witnessed many marrow in prognant wom in is accompanied cases in which paraplegia had existed for a by abortion. In another form of myelite, where there is little reacchief, and the bones which compose the tion, but a greater tendency to collapse, the canal, with the most scrupulous attention. nterus partakes in the general impression, It may seem strange that so grave a lesion is struck with inertia, and the acconcheur of motility as paraplegia should exist for a having in vain tried to stimulate it occurraction, is forced to have recourse to artificial change of structure in the organ which remeans of delivery. However, these phe gulates voluntary movement; but such, I nomena are far from being frequent or repeat, is often the case. The same thing general. The premature expulsion of the is seen in the brain. As we advance with foctus is by no means a necessary conse-the present course you will have occasion quence of myelite, and you will see many to see many other examples, and to convince women who present the symptoms of my yourselves that in nervous diseases the true clitis in a well-marked manner, continuing cause of the functional disorder but too to bear the fruit of conception without any often escapes the researches of the most experienced anatomist. On the other hand. we have grave and extensive lesions of the brain, which declare themselves by no symptom whatever. We have cited cases of ra-From the observations which we have mollissement, of suppuration, occupying a now laid before you, you may perceive what considerable portion of the nervous suba variety of symptoms accompany the de-stance, and yet the phenomena of sensation velopment and march of inflammation of and motion were absolutely unaffected. These the spinal marrow, according to the nature, cases deserve to be compared and contrasted with the former; they show the immense difficulties that surround us in every step we take in the study of nervous disorders, and point out the necessity of observing with minute care the most trivial points, in the hope of one day arriving at the solution of questions which at present are beyond our comprehension.

In numerous cases of myelite the symptoms are so equivocal, so slightly marked, as to escape our notice altogether. In many other cases we have phenomena, which, however grave, we cannot attribute to any permanent organic change of structure. we have seen an hysterical female who remained paraplegic for several days, and then suddenly recovered the use of her lower extremities. In other cases the patient becomes blind, or has an obstinate contracand yet it may be impossible to up tion of one or more limbs, and yet these ion externally. Here, then, symptoms will disappear more suddenly greatest attention, and no than they were produced. Again, look at the ball, to determine the paralysis that sometimes accompanies

poisoning by lead, or what is called "co-| Mesers. GRIFFIR, TEALE posenting by lead, or what is called the lica pictonum." Here certainly we have no realize the part, and English to gene-injury of the spinal marrow. In these, and ralize the part, with the observed, many other cases, the lesion, whatever it and reduce them to certain principles. Let many other cases, the lesion, whatever it may be, escapes discovery; it is in vain that you will seek to explain the functional derangement by an organic change. Unfortunate is he who obstinately persists in such a path. Truths that are familiar to others will escape his notice, or be rejected without examination; the search after a chimera will distract him from more solid oursuits: he will remain for ever at the portal of science; he may knock, but will never enter.

Dr. Esquinor relates a case in which the lower extremities were completely paralyzed during life, and what do you think he found on examination of the body? He found two cancerous masses occupying each anterior extremity of the cerebral hemisphere. Here, certainly, according to the received ideas, the lesion should have occupied some portion of the spinal marrow. This is a remarkable case; we find the brain usurping. as it were, the functions of the chord, and giving rise to a lesion of movement which is especially connected with diseases of this latter organ.

Another observation, equally worthy of attention, was published a short time ago in the bulletins of the Anatomical Society. Here the patient also suffered from paraplegia; the lower extremities were paralyof the disease was naturally sought for in the spinal marrow; but the nervous substance was every where perfectly healthy. It was observed, in opening the body of the patient, that the bones were remarkably friable, and this led to further researches, which revealed the true seat of the disorder. The heads of both thigh-bones were completely destroyed, and hence the pseudoparalysis, as we must call it, depended not upon a want of nervous influence, but on the simple circumstance that the limb was incapable of being moved, because the upper part would not stir. We merely notice this case to show, how necessary it is in medicine to observe everything with the strictest accuracy; for although pathological anstomy may not give the key to all the functional derangements that present themselves in the course of disease, yet we should never neglect to pursue it with ardoor, and scrupulously examine every circumstance that may tend to throw light on their nature and causes.

Simulations of Myelite.

In speaking of the diagnosis of myelite, we mentioned that certain affections simulate in a very close manner diseases of the spinal chord: it is only within the last few years that this part of the subject has been studied in a regular manner, particularly in England and Germany, where 14, of Run's Magazin for 1

BEL, HINus enter into some details upon the subject, which is not without interest, especially as you will not find it the standard upon in any of the works in your hands; indeed the subject is one new to myself, and I am indebted for my information to the analysis of the works of Messrs, GRIFFIN and Ens, published by the Gazette Medicale. If you wish to refer to these, you will find the annlysis of Mr. Grippin's work in No. 18 of the journal for 1835. The notice of Mr. Ess's was published a very short time ago in No. 46 of the same journal.* The gentlemen whose names we have just quoted, describe an

" Irritation" of the Spinal Marrow,

whose principal characteristic is to produce a symptomatic irritation in some other part or organ of the body. It is not inflammation, but a disease sai generis; in a word, what we call "irritation;" and leaves no trace of organic change after death. Let us see how they establish the existence of this malady. Suppose the patient is affected with palpitations of the heart, weight and construction about the pericardial region; a feeling of suffocation, frequent pausea, fainting, Ac.; they exercise pressure along the tic. On examination after death, the seat spine, and when they come to that portion of it which corresponds to the irritated part of the spinal marrow, they pretend that all the symptoms are aggravated by the pressure. When the stomach is the organ chiefly affected, pressure over the spine increases the nau-ca, the vomiting, the pyrosis, the pain in the hypochondriac region, and other signs of gastric irritation. If it be the head, the exphalalgia and nervous pains are considerably augmented. Whenever phenomena of this kind are witnessed, that is to say, whenever according to Dr. Ess. "a sensibility of a greater or less portion of the spinal marrow to external pressure, coincides with a corresponding pain in some other organ, which we can augment at will by that pressure, the disease consists in an irritation of the spinal marrow, whose scat is indicated by the tenderness of the rachis." According to Mr. GRIFFIN, it is not necessary that any temlerness should exist over the region of the spine. If pressure excite pain in the distant organ, the point of the spine at which this phenomenon commences, is the part affected, although it may not itself be the scat of any lesion of sensibility.

All this may be very true, but it remained to be verified by further observation. must confess that to me the idea of pr

^{*} Dr. Enu's paper to :

ste upon a sin creasing, at will, headsche, or other part of the body, especially when the spinsl marrow does not exhibit any symptom of disease, — all this, I say appears to me to par-take a little of romance. However, we must we said before, all this remains completely examine the subject more carefully before we can judge. In medicine, facts are not to he rejected because they may seem a little extraordinary.

The observations of the same physicians tend to establish that a great number of neuralgic affections, attributed commonly to the fifth pair of nerves, really depend on the to. This they establish in the way just al- resume the luded to. The patient has, perhaps, a pain in the superorbital region, in the jaw, &c.; pressure over the upper part of the cervical vertebra invariably augments this pain, if connected with spinal irritation; hence the the spinal marrow, and not in the branches The respiration is often embarrassed; in some cases the patient has accesses of suffocation, always increased by pressure on tribute in a great many cases to irritation having been implicated during the course of of the spinal marrow, and we can admit it of the disease. ourselves amongst the causes.

Again, Messrs. GRIFFIS and Exs speak of a peculiar pain in the region of the sterdays ago I had occasion to see a case that toms of reaction, you must take blood from one would have been inclined to arrange the arm; if the fever he mild, you may conunder this class. A gentleman called upon tent yourselves with an application of leeches me at my house for advice; the only symptoms at my house for advice; the only symptoms in presented were, a well marked according to circumstances. of the spine in- ever, the case I now mention is merely a negative fact, and proves nothing against the facts distant established by Mesers. Ens and GRIPPIN. In the abdomen this irritation may simulate several maladies, such as vomiting, colic, to be verified before we can admit it into the science: moreover, it is only an extension of the facts which we have noticed when speaking of myelite and its symptoms. But it is probable that some forms of asthma may depend upon inflammation of the spinal marrow; yet there is still a vast distance between the two ideas. So much for the irritation of the spinal marrow now alluded doctrine of "spinal irritation." Let us now

History of Myelite.

The duration of this disease is very variable; sometimes it may terminate in a few true seat of the disease is to be sought in days; at other times it is prolonged for a considerable period, and may last for eight of the nerve, as we have been accustomed or ten years. It may terminate in a cure; to think. In the chest, this affection may but whenever inflammation of the spinal give lice to symptoms which simulate marrow is well marked, the disease is grave, phthisis. A cough more or less obstinate is and the prognosis unfavourable. In cases the most common symptom of irritation of where death results, this latter termination may arrive in a different way: 1st. By extension of the inflammation upwards towards the brain: we have already noticed the tendency of myelite to propagate itself upthe superior nerves. Many observations wards. 2nd. By extending to the respiraalso show that several pains existing about the pasietes of the chest, and mistaken for the uniation, depend on this same "spinal" the Where none of these three organs is affordated, the united that the same of these three organs is affordated. incination, depend on this same "round; affected; the patient sinks gradually; he becomes in much more trobable, and is wastes away; the exposed parts of the body phenomenon is much more probable, and is wastes away; the exposed parts of the hody consistent with what we know of the effects submitted to pressure ulcerate, and he dies of chronic myelitis. A disease of common in a state of complete exhaustion. ST. THOMAS'S HOSPITAL

CLINICAL LECTURE

ON CASES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE I. - DISEASES OF THE HIP-JOINT

GENTLEMEN, -I intend to-day to address to you some observations on diseases of the joints. I have under my care at present many of those cases, and as the histories of several of them have been collected, I shall briefly relate the particulars, subsequently commenting on them, in order that you may trace the progress of diseases affecting the articulations so far as you are thus afforded the opportunity of doing so. Perhaps no subject in surgery is more important. They are productive of extreme distress to those who are the subjects of them, and the surgeon cannot be too careful in investigating them, and in distinguishing the means of cure. To four cases, in particular, I shall now direct your attention.

Case 1 .- The first case is that of a patient with disease of the hip-joint. The hip is as frequently affected as any other joint, and perhaps its diseases are of more importance than the affections of any other joint. There is a man in Abraham's Ward, named Edward Carpenter, aged 56, from Bermondsey, who was admitted on the 8th of October, under my care. He stated that he had been regular in his habits, and that ten days previous to his admission, while lifting a sack of seed weighing about three bundred pounds, he experienced a sudden and severe pain in the left hip, extending to the loins, which obliged him to discontinue his work. On the following day, the pain still continuing, he obtained relief to some extent from cupping upon the buttock, according to the directions of a medical man to whom he applied. Pain in a short time was felt also in the knes, extending down the internus. Blisters were applied at this time, but without much benefit.

On admission he had a dull aching pain, principally situated at the anterior and inner part of the knee; and this pain was more articularly aggravated towards the evenpain. The left buttock was somewhat flat-tened. Pressure over the posterior part of the hip produced only triffing area. the hip produced only trifling pain. Upon Case 2.—Septime further investigation this limb appeared to aged 19, residing the rather longer than the other; this intemperate in seemed to arise chiefly from the chiefly of on the 8th of

and the same of th

slight wasting of nent of the thigh produced stone res of pain. The pain. the knee was not increased by flexion or extension of the log. The sleep was dis-turbed by the pole at night. His general health was pretty good.

I directed an occasional aperient to be given, of senna and salts, and officred a moxa, of about the size of a shilling, to be applied to the left groin, about an inch to the outer side of the femoral vessels. I further ordered that he should have a grain of the acetate of morphia, with a view to allay the pain and to procure rest, and that

he should keep his bed.

13. The report to-day was, that he had rested better at nights, and the pain of the knee somewhat diminished. The slough of the moxa, though partly, had not entirely, se-parated.—Next week the account was that he complained of pain on the inner side of the knee, extending down to the ankle. Pressure did not produce so much pain. The discharge from the mova was trifling. 1 found at this time that he had been used to a certain quantity of stimulus, and as his general powers were failing, I directed that he should have a pint of porter daily, in dition to the medicine which had been to dered.

27. The mova is discharging freely, and the pain is greatly relieved. He can move the limb without difficulty. The limb appears now to be of the same length as the other; sleeps well at night; the appetite and general secretions are good; howels open.

30. He is not quite so well. The pain in the knee has become more severe. He has had but little rest at night, and the moxa has ceased to discharge. Probably that, and a change taking place in the weather just at this time, would account for the ag-

gravation of symptoms.

November 3. Pain in the knee severe, particularly on the inner side. Pain in the bip, upon pressure on the anterior part, but not much when pressed posteriorly. I directed another moxa to be applied, in consequence of the aggravation of the symptoms, to be placed a little lower than, and anterior to, the first, which was a little more inner side of the leg, as far as the malleolus distant from the joint than I could have wished.

11. Up to this period he has been progressively recovering. The pain in the knee is but triffing, and pressure on the hip produces no pain. There is slight numbered down the inner side of the leg, but only

about five months and the state of the first trace, which obliged him to discontinue his labour for a time. His pain was relieved by rest, so as to enable him to resume his work; but he had not entirely got rid of it. In the course of the second day after he had returned to his work, the pain came on more Severely in the knee, and he then applied for medical aid, and had blisters placed on the knee, but without any beneficial effect. On his admission, he complained of an aching pain on the anterior and inner part of the knee. I examined the hip-joint, and found that pressure on the groin produced pain; sudden abduction of the limb also produced pain. There was no appearance of the limb being longer than the other, but there was a little flattening of the buttock. As his tongue was not clean and his rest was disturbed, I gave him a small opium; and the symptoms being trifling; I ordered an emplastrum lytta to be placed on the groin.

14. The pain in the knee is somewhat relieved; he rests well at night; complains of headache. He was now ordered to repent the blister, as the former had closed. I had only directed that it should be dressed with simple ointment, or a positice. A week afterwards he had no pain, except on pressure being made over the anterior part of the hip-joint. But six days afterwards there was a relapse, and he complained of pain in the knee, particularly on the outer side of that joint. Pressure over the anterior surface of the hip-joint gave rise to pain. Any movement of the hip whatever, was attended with uncasiness. I now directed a moza to be applied to the groin. At this time there was no indication of any disturbance of the general health. Still I have no doubt that that disturbance of the general health had commenced which was afterwards observed.

Nov. 3. Pressure increases the pain. He says he has a general numbress of the foot. having, as he states, caught cold.

- than usual, and he has a cough. He was now directed merely to take a little efferveseing mixture.
- 5. Passed a bad night, and complains of Sas. to be applied to the

at he has had !

but little rest; the soreness of the epigustrium continues, but the skin is moist; pulse a little softer, and the tongue getting clean. In conrequence of the cough and pain, I directed him to have some of the Dover's Powder, and to take a drachm of the spiritus ætheris nitrici, a drachm of the sirup of poppies, and ten drachms of the camphor mixture, -a medicine calculated to act in some degree as a dinretic, and also to keep the secretions of the skin and bowels a little excited. Next morning it was found that he had passed a better night, but he still complained of pain in the knee, which was in-creased upon any motion of the hip. Pressure over the anterior and inner part occasioned more pain. Twenty minims of ipe-cacnanha Wine were now directed to be added to each dose of the medicine.

29. The rest is much disturbed by the pain in the knee, and the cough is very distressquantity of calonicl with half a grain of ing. Yesterday there was a good deal of pain in the left hypogastric region. There is pain in the epigastrium. The breathing is rather hurried; pulse 84, and very compressible; skin cool, and bowels open. I directed that he should take a small quantity of mercurial medicine, and that there should be a blister applied over the left hypochondrium. This is the case as it presents itself at present; the local affection is aggravated, and the case is a good one as illustrative of points which I shall presently note.

Case 3.—The third case is one of chronic inflammation of the fibrous capsule of the hip-joint; it is the case of Thomas Lachev, aged 11. residing in the city, admitted October 7th, into Abraham's Ward. He states that about four months ago he experienced a sudden pain in the left knee, but from no particular cause of which he was aware, and that it always increased towards evening, and after taking exercise. For this he was admitted into St. Bartholomew's Hospital, when he had two issues placed upon the hip, just over the trochanter major. It is now quite clear that he is labouring Those issues having relieved the pain, under the full effect of febrile irritation, he was discharged as cured. In a short time, however, the pain returned with increased violence, and in about a week af-4. He has still more general symptoms of terwards he was admitted into this hosfever; severe pain in the head; skin hot, pital complaining of pain of the anterior tongue furred, howels open, pulse quicker part of the hip upon pressure over the trochanter major. Any motion of the joint increased the pain. His rest at night was disturbed, but his general health was pretty good. From the severity of the disease and reness about the epigastrium. He its duration, I directed the maxa to be emtook a dose of rhubarb and calomel, ployed; and from the feebleness of the is likewise ordered to take the house general powers, which were rather below the former did not act. A blis- par, I ordered that he should have some porter in addition to the ordinary dies of the house. The affected limb was longer than the other.

13. Very much relieved. The affected

limb is still a little longer than the opposite ! Pressure produces slight pain.

21. The lengthening of the limb is but fibrous chi much better.

sented as cured.

was admitted into Queen's Ward on Sepand the blisters were kept open, but she derived no advantage from them. Upon her admission she complained of pain of the anterior and inner part of the knee. The pain in the hip was more severe than it had been, and was increased by pressure over the trochanter major. Her general health was much deranged. I ordered that a moxa should be applied over the trochanter major. which gave but little relief. I then directed that a second moxa should be applied to the groin, which relieved her considerably,

Oct. 4. There is less pain; she sleeps better at night; perspires towards morning; the left limb is nearly an inch longer than the right; the buttock on the affected side is flattened, and the general health is impaired.

13. Much improved. To take the decoction of sarsaparilla twice a day.

20. Little alteration.

24. Pain a little greater; passed rather a bad night; the limb apparently is somewhat smaller than it was upon her admission.

28 Pain rather severe, but it does not disturb her rest; there is evidence of additional weakness, from copious perspirations; the discharge from the moxa has ceased.

Nov. 5. Rests tolerably well at night, and the moxa is nearly healed.

11. Pain in the knee yesterday, and increased by the slightest motion of the hipjoint. No pain in the knee to day. Can bear pressure better on the posterior part of the hip, but when pressure is applied autoriorly, it produces some pain. I ordered that a second moza should be applied.

Disgnosis, Pathology, and Trentment. - and the sound parts, from the loins to.

These cases all have reference to diseases of the knees, you would see the design the same articulation, and three of them the butsock on the ad present very nearly the same symptoms. In division between the the first case we find that inflammation was being lost. produced in the hip-joint by a riolent sinsin. obliquity of 2

we know that e attached to the oint, their tend trifling; the pain has subsided, and he is being connected with the capsule itself; so that by violent exercise, such as raising a 29. I found he could walk without pain; heavy weight, there might be laceration of there was now no lengthening of the limb; the tendons of the muscles, and of the the left buttock had nearly regained its fibrous capsule itself - a very probable cause natural size, and he was on this day pre- of such inflammation. We find the pain extending to the loins, probably from some Case 4.—The next case is one also of slight strain of those parts, and not as being chronic inflammation of the fibrous capsule; connected with injury to the hip. After in-of the hip-joint. Sophia North, aged 26, a flammatory action had been set up, and simbousemaid, living at Farnham, in Surrey, ple means had failed to relieve the patient, was admitted into Queen's Ward on Sep-latin at the anterior and inner part of the months ago she received a blow on the left hip, from a fall. The part in a short time became swollen, and she experienced con-siderable pain in the joint, and also at the thing, and pressure produces an aggravation that is a point of importance. The fibrous siderable pain in the joint, and also at the that is a point of importance. The fibrous anterior and inner side of the knee. The capsule of the hip-joint is very extenpain was of a dull character, and disturbed sive, but not so extensive as the mu-her rest. Leeches and blisters were applied, cous or the serious membranes. We know that in inflammation of the peritoneum, the pericardium, the pericranium, and so forth, inflammation extends very quickly along them. But if you take the capsular ligament of the joints, you will often find organic thickening taking place at one part of the ligament, while the other parts remain unaffected; and the pain of the anterior part of the joint denotes that the morbid affection is confined to that particular part. This is indicated by the sympathetic pain which affects the knee; and it is upon the anterior and inner part of the knee that the patient feels the pain. You can account for that by recollecting the armomical structure, and the distribution of perves to those parts, -the division of the anterior crural nerve, and the saphenus major and minor, one of which is continued to the foot, and the other is lost above the knee, on the inner and anterior side. It is of much importance to attend to this, because the closer in contact with the affected part that the remedies can be applied, the more likely are they to be of service. Frequently you will find that there has been an indiscriminate use of applications, or abstraction of blood, over the posterior part of the hipjoint. You generally find that blisters or moxæ are applied there, which are not likely to do one wixth of the degree of good that they will do if applied to the groin, near the sent of the disease. It becomes, therefore, of much importance to ascertain accurately , the symptoms, and whence they proceed. Next, there is flattening of the affected

buttock. This is the case in all the patient Taking a posterior view of the diffect

lengthening the affected limb, the Library aid, admit of a difference in the rists of the ilium, the state of the affected side, and for that purpose he is upon the application of very slight force, continually throwing the weight of his body. We have thus an explanation of the period of the p

you would find that you could draw the head of the femur from the acetabulum, to the extent of about an inch, or an inch and a half. The head of the femur, then, is kept against the acetabulum, in the healthy state, by the influence of the surrounding muscles. All the muscles which pass over the hip-joint have a greater or less influence of this kind, but more especially those which are immey connected with the joint. Accordingly had that if, with forcible means, we pull new logs, the healthy femur is still kept the acetabulum, by the tension and muscles; whereas the sepad bone from the aceta-

immediate seat of disease. The muscles amongst other modes of examination, tries of the leg become affected, so that its power the length of the two limbs. He is surprised a much diminished. The condition of the to find a difference of an inch or more in glutei muscles gives rise to this flattening of the length of the two; but then he fields he buttock, when the patient is in an erect that there is free motion of the joint of the position, occasioned by the want of con- affected limb, and not a great deal of unraction that results from the adhesion of easiness created by the movements. Now if he integuments over the affected part. It he was not aware of what I have just mens, therefore, from the loss of the natural tioned, he might pursue his inquiries to power of the muscles to contract, that you satisfy himself whether there was not really have that appearance. On the sound side a dislocation; but recollecting what I have the proper muscular contraction takes place | stated, he is aware that this occurs from the The affected limb is frequently said to be result of the injury,—that the muscles lose longer than the other; but the fact is, that their contracting power for a time, and, as a person who is the subject of an affection a consequence, allow of the separation of of the hip is always endeavouring to relieve the head of the femur from the acetabulum.

We have thus an explanation of the pain obliquely upon the sound side. The one of the knee, of the flattening of the buttock, crista ilei may be thrown an inch or an and of the apparent lengthening of the inch and a half higher than the other; and limb. We may also explain the diminished even if you put the patient into bed, in the size of the affected limb. In the case of such recembent position, you will still find a an injury as I have alluded to, we know slight degree of difference in the length of very well that the larger muscles, those the two limbs. But there is another very important point when that is the case, there will be an apto be noticed, which gives use to the apparate parent difference in the circumference of rent lengthening of the affected limb, even the two limbs, because all muscular fibres in when the patient is recumbent; and that is a healthy condition have constantly a tenderous the formation of the hip joint. The capsular ligament of the joint, which comes it through, as in amputation, and you will from the acetabulum, embraces, as you are immediately observe that there is a strong aware, the head and neck of the thigh-bone, disposition in the fibres to contract. By symand owing to its construction this joint ad pathetic influence, therefore, the muscles of mits of motion in every direction,—abduc- an injured limb become flaccid, and lose tion, adduction, flexion, extension, and I may their tendency to contract, therefore the disay, every intermediate metion. We know ameter of such muscles will be different from that the capsule is longer than is absolutely that of sound muscles. There may be the necessary to retain the articular surfaces of same extent of muscle, but still, if you meathe one bone in contact with the other; so sure them, you will find that there is a difthat if you were to strip off the whole of ference in the diameters. However, after a the materials from the capsular ligamout, time, or from disease, the muscles actually diminish in size; there is a diminution of the muscular fibres. This becomes very apparent in a case where the disease goes on to ulceration, or even to a more extended

stage of disease.
We have seen in each of these cases, that the pain is increased in the knee on motion of the hip-joint, and not increased at all on motion of the knee-joint. These are important points for you to keep in mind. Again, you find, in the second case, that the patient described himself as having ex-perienced an injury of the knee, and he but; whereas the sepa-bone from the accta-played, as having been directed to the knee-the difference in the alone,—blisters and leaches,—but they did n; and that may, as not afford relief. Now a surgeon should, in

such a case, immediately direct his attention in the retirials of the to the hip joint, where he would find the in as we have trid to the hip-joint, where he would find the tar as we have the search the form true source of the disease. But the point is of the disease. But the point is of the disease. The disease is that the knee, and resulting from disease in that the currentling, point out the situation of the joint, it will necessarily be increased by modificate and the particular tenture affected. tion of that particular part of the limb. If, therefore, we find, upon putting the finger over the ligaments of the knee, or on pressing the synovial membrane, that the pain is not increased; or, again, if we flex or extend the leg, which may easily be done withthe motion does not increase the pain, then we must immediately look to the hip, knowing that sympathetic pain of the knee is almost the only symptom which indicates in the case I now allude to. Examination of the knee did not enable me to detect what I have to say by-and-by.

The pain in these cases being aggravated influence the disease. joint. The same is observable in inflammation of the pericardium, and the same in find blistering the chest do good. Againflammation of all the fibrous tissues, blistering the abdonen in peritonisis, The patient is perhaps well in the day, but towards morning or evening the pain is applying counter-irritation to distant a greatly aggravated. It is a kind of inter-has a good effect as regards the distant mitting pain, of a dull, aching, but not land of the disease, wherever it is a land of the disease, wherever it is a land of the disease. cinating or lacorating character; quite sol- ways better, wherever you ficient, however, to disturb the rest, and se counter-irritant as a produce exhaustion in that way. Such, then, tease as possible.

ent symptoms

We way know, from Now as re in these instances. the observation of circumstances which I shall relate in connection with other cases, that the disease has not extended to the synovial membranes, nor to the cartilages; out moving the hip-joint, we discover that It has not extended so as to produce ulceration or disorganization of those parts, but consists simply of slow inflammation of the fibrous tissues, therefore the remedies to be employed are not of a severe kind, conincipient disease of the hip-joint. So it was stitutionally, nor very much so locally. In the first place we ought to ascertain whether the disease is connected with, or dedisease of the knee; I therefore proceeded pendent upon, any peculiar condition of the to an examination of the hip, and a super-system. We find in most of the cases be-ficial examination of that joint enabled me forc us, that the general health is good; at once to ascertain the disease was there, there is only one case out of the four related, Again, the situation of the pain affecting in which the state of the general system in the knee is not that which is the result of fluenced the disease. In two of the others disease of the knee-joint itself. The pain the patients became a little exhausted, perwhich has been observed in most of these haps from confinement to bed, and the discases, has been of the anterior and inner charges from the moxic. I was induced part of the articulation; and we find that from this circumstance to give them a quantitate denotes the situation of the disease to tity of such stimuli as they had been used be of the capsule of the hip-joint, for each loo. But as to the loved applications, or mapatient complained of pain in the kneet agreement, the first, and perhaps, the most impact of the control of the cont when pressure was made about an iach to portant object is, that the parients should be the outer side of the semoral artery, over the kept at rest. They will find out the position situation of the capsule; but on all parts which is most comfortable for themselves, posterior to the trochanter major and tube-rosity of the ischium, when pressure is made, some support under the ham; a mail pil-you find they suffer but little. When the low, for instance, between the ham and the pain in the knee results from disease of the bed, and keeping the limb flexed. They knee itself, you will detect that cause by will themselves move the pillow as they pressure upon the knee, or motion of the move the position of the limb. It is not knee-joint, as it will then arise from fibrous accessary to confine or restrain the motion disease of disease of the synovial menchane; of the joint entirely. Murely moving the you will appreciate this more distinctly from limb in bed may be sufficient for the confert of the patient, and not likely injuriously to We find that the at night, is indicative of disease affecting the best mode of relieving the inflammation of fibrous tissue. You see this very clearly in the fibrous tissue, which is generally a sub-inflammation of the sclerotic coat of the eye. You can detect inflammation of this texture irritation; and we know that counter-irrivery readily, seeing that the surrounding tation to a distant part from that which is structures are free from inflammatory ac- affected, and to which you can make no imtion, it being alone the seat of disease: and mediate application, is often productive of when thus singly affected, we have symp-good. For instance, we find blistering the toms, such as I have mentioned, indicative of head or neck in diseases of the brain, pro-inflammation of the fibrous capsule of the ductive of headfell results. So in pagemonia, or inflammation of the pleura, we even in enteritis, is advantageous.

are of inflammating the brain, or of the make a greater call upon the constitution nembranes of the the state of the state neck. Again, if we apply a blister to the in such cases a repetition of blisters is in-interior part of the chest, where the parietes finitely better than keeping one perpetually are thin, we effect more good than by ap open. If it be a disease that will not yield dying it posteriorly. There the parts are to a blister, or a repetition of blisters, it is ery thick.

I have directed your attention to the situation of the pain in these cases. If the min be in the anterior part of the knee, you will find the disease to be at the anterior part of the capsule of the hip joint. If it be n the ham, the patient will experience more min behind the trochanter; and in such a case, instead of employing the moxe, as we save done in all these cases, in the groin, I should apply them on the posterior part, between the trochanter and the tuberosity if the ischium, over the posterior surface of the capsule of the hip.

When the symptoms are very slight, I have often found a blister on the surface combined with attention to the secretions, suppose it has proceeded to some extent in the library tissue, it is better to resort to the more severe remedy of the move. The we have thought it necessary to procure move is the description of counter-irritation rest by artificial means, by morphia or which we now usually employ, and a very opinin. The quiet produced in that way is more severe remody of the mova. The good mode of activing counter-irritation it is tayourable to the restoration of the natural I have known patients who have bad the state; and your medicines or local remedies move applied, and have had issues formed have a much better opportunity of doing have given the preference to the moxa, though one might be disposed in the first instance to say that they would rather object to the moxa, and be content with the other. Still, any of these will have the same beneficial effect.

It is not my practice here, and this is the result of experience, to keep the moxa open | we find that the cure has been interrupted by the use of any extraneous matter, so as to j by general disturbance. The patient, as he form what is usually denominated an issue; nor to keep a blister open. The cases I have related are, three of them those of adults, and one the case of a boy; but this is a very common disease at an early period of life, more common than at a more advanced age. Children at the age of two or three years, immediately on beginning to make progression up to the age of puberty, show a disposition to the setting up of such disease. In such children it is not an ancommon practice to employ a perpetual blister, as it boy is not strong, he is rather of a scrofulous called. A blister is applied, the cuticle is habit, and the general powers have been made and then an ointment, composed of lessened by this attack on the general

patient most amazingly. I have found that in such cases a repetition of blisters is inbetter to employ the moxa, as the irritation of the mora is not attended with pain, nor does it make the same call on nature that a large blister does, which is kept continually open.

The same reason I have against the continuation of an open blister, is applicable to the continuation of an issue; for if in the case of an issue you use beads, or beans, or peas, there is a great drain on the constitution, a great irritation kept up, and, in fact, an aggravation of the disease. In the ordinary cases, such as I have detailed to you to day, the use of the simple moxa. allowed to heal, and then applying it again, if need be, is much better than introducing any extraneous matter for the purpose of produce all the effects to be wished for keeping it continually open. It throws off a slough, and yields a certain discharge. and rest. If the disease, however, has been which is as much as these cases require, of longer duration, and you have reason to imbenendent of attention to the accretions. and any other necessary local treatment.

In one or two of the cases we have had by nitric acid and by potassa fusa, who good if the patient he kept quiet, than they have where the rest is disturbed, which it

usually is from his sufferings.

The treatment, so far as regards these cases, has been beneficial; one case has been presented cured, and two of the others may be considered as convalescent

In one of the cases which I read to you, states, caught cold, and has got rather a severe febrile disease upon him. You must suppose that sometimes local disease becomes aggravated during the prevalence of fever, which is not connected with it. This is the case here. The fever is not sympathetic. but it has been induced by cold, and therefore induced by a cause which is entirely independent of the disease for which the patient came in. The fever, however, has had its influence on the local disease; the magintment and anguentum lytte, is system; the consequence is, that the local it, morning, noon, and night, for affection has become aggravated, and will of exciting a discharge. A dis- | continue so till we have subdued the febrile in that way, but greatly at symptoms, and rallied the general powers, by The irritation appropriate remedies. At present he is un-id, is such as to der the influence of such remedies, marely, as are calculated to check the influence of rynz, with great the fever; he is not in a situation to be tonics, but as soon as he is they will be given, and you will find the local symptoms will again be subdued after the fever has been overcome, and he is restored to better

I am afraid the time will not allow me at present to go into the other cases, but they will be more valuable for observation hereafter, as they will then show more of the process of cure.

ST. THOMAS'S HOSPITAL

CLINICAL LECTURE

ON A CASE OF

CHRONIC GASTRITIS.

Delivered in the Session 1835-36.

By DR. ROOTS.

speak, gentlemen, is a case of chronic or of spirits, chiefly of rum, but that he had bowels open, the motions dark. been generally healthy up to about three 5. maining

ward case. The man was clearly suffering racter, but the inflammatory action may be under chronic or sub-acute inflammation of the mucous tissue of the stomach. There accompanied by increase of heat not sensible are two forms of the disease, the acute and to the touch.

In the early stage, the symptoms are very fatal. The other was the case of a poor sia, functional derangement of the stor

se of heat, I disseised cur in the acute form, we frequently meet with the affection in the sub-acute or chronic form; and the disease advances so slowly, that it may be readily overlooked, and only discovered when the mischief is beyond relief. Generally speaking, however, strict to detect it when it does exist.

The ordinary termination of the chronic form is generally in ulceration, or thickening, or softening, of the mucous and sub-mucous tissues. The ulceration may conness. He was directed in consequence of sist either in a considerable number of size, affecting either the mucous tissue or the follicular glands of the stomach. As the process of ulceration goes on, the surroundapplied there, and afterwards the liquor excite adhesion to some neighbouring organ, plumbi subacetatis diintus was constantly the ulceration may extend through the peemployed, with directions that he should ritoneal coat, and allow extravasation of take in the morning half an ounce of castor the contents of the stomach into the abdooil, and on the 13th the swelling, and tender- minal cavity. Many such instances of the ness, and heat, had in a great measure sub- progress of ulceration, from the chronic insided. On the 16th he was still more im- flammation, have occurred, without preproved, and he was directed to take his me-vious suspicion that such a condition of the dirine only three times a day. This on the stomach existed. Such extravasation would 18th was reduced to twice a day, with an set up acute inflammation of the peritoneum operational dose of castor oil. There is no of the abdomen generally. Sometimes, uneasiness of atomach, no heat of throat, no however, nature prevents this by adhesion sickness, no acid cructation after food; the to the liver, the spleen, or sometimes the appetite much improved; getting quite well; colon; still of course the disease will ultipulse 85, rather small, but quick. On the matchy prove fatal, though without extrava-

quinitie to be taken twice a day. On the extending from the stomach along the esophagus to the pharynx; thirst, diminished 27. Being now perfectly well, he was pre- appetite, nauses, and vomiting. Commonsented, with, I should say, no disease re-ly, also, I believe, you will find tenderness on pressure at the epigastrium, sometimes, Now this was a very plain straight-for- as in the case I have read, of a severe cha-

the sub-acute, or chronic. The scute form is not. I believe, very frequently met with. I often only those which are common to dyhave only seen two examples of pure acute spepsia. I do not, of course, admit the existinflammation of the mucous tissue of the ence of such a disease of itself as dyapepsia, stomach since I have been in practice. One difficult direction. In point of fact, that must of these occurred in a young lady the near be dependent upon some cause, or a variety relative of a medical gentleman at Camden- of causes, often, in different cases; but we town. The disease ran its course and proved understand commonly by the term dyspepration. The other was the case of a poor sia, functional terangement of the season man, in Somers-town to whom I was called a manner of the poor stated of English cholers some by any change in the tissues. Let us see, because the state of English cholers some by any change in the tissues. Let us see, because the state of English cholers some by any change in the tissues. Let us see, by any change in the tissues. achlity, eructations, flatulence, and oppresdoes not often or- sion after taking food, frequently with some

degree of pain in the stomach. These are ing generally and local common to chronic inflammation of the stomach, in which, very often, the patient complains only of pain after taking food.— her that pain, too, frequently ceasing entirely as digestion is completed, the patient in many instances saying to you, "I am quite well; I only know that I am hungry; I take my food; I only know that I am ill for such a pain is much more prominent, extending often to the back from the stomach. Again, bowever, I would impress on you, that actual pain, unless you use pressure, is frequently denied, though patients will confess that about the stomach; and occasionally you will find all these symptoms attended by and anxious, the vomiting more frequent, pulse at the same time is generally small, tharp, and occasionally accompanied by some degree of hardness. The tongue also most commonly exhibits some evidence of the disease. I say most commonly, because the tongue is not always a faithful indicator of inflammation of the mucous membrane of the stomach, though generally it is red nearly all over,-very often white at the back and centre, but morbidly red at the point and the edges, -sometimes covered by small aphthæ, and, as in the case related, by minute ulcerations also. But I again urge upon you, that you must not, because the tongue appears natural or white, conclude not understand me to coincide with some that gastritis does not exist. I have seen several examples of well-marked gastritis, where there was nothing in the tongue to indicate that fact. Generally, however, it is a tolerably good guide.

As to the causes of chronic gastritis, abuse of diet, eating imperfectly-digestible substances, the abuse of spirituous liquors, and protracted errors in diet, are all likely to be exciting causes. Suddenly drinking a large quantity of cold fluid, the surface of the body, perhaps, being much heated, or, more likely, the nervous system being much exhausted, has been not an unfrequent cause of inflammation of the stomach.

With respect to your diagnosis, it is probable that you will understand all that I wish you to comprehend on this subject, by going at once to the treatment. In inflammation of an organ so essential to life, antiphlogistic measures must invariably be employed, both in the acute and in the sub-acute or chronic form of the disease. Bleed-face. The aphthe about

measures of t there is ary importance, much activity in the Never . ke blood from the arm; let nothing prevent your doing that, unless you are stimled that the discase hus been preduced to such an extent that the powers of the preduced not justify that incasure. Depend on it also, that you time after taking food." In other cases the will be much more likely (I speak now of the sub-acute form) speedily to subdue the inflammatory action by one or two general bleedings, than by relying upon local bleedings alone, and more especially where vomiting is urgent. You will remember, there is a sensation of weight or oppression that with respect to the man whose case I have related, I did not hesitate to take blood from his arm, and that it was buffed pyrosis,—by the ejection of a clear, some- and cupped, and that the symptoms were limes viscid, sometimes quite thin fluid, to thus somewhat relieved, the venesection the amount of from half an ounce to an not being required to be repeated. The nance and a half, sometimes tasteless, subsequent application of leeches freely to sometimes acid, and sometimes both acid the epigastrium was sufficient. But if the and bitter. Generally, however, as the dis-symptoms had not given way, if the vomitsase advances, the symptoms become more ing, the hierup, the heat of the stomach, had argent; the heat in the stomach is more continued to be as urgent as before, I should listressing, the countenance becomes pallid have directed a second, perhaps a third, and perhaps a fourth abstraction of blood from and occurring after every ingesta. The the arm, before I began to rely on leeches alone.

> In conjunction with bleeding, you will find counter-irritation of considerable advantage, but to this I would not resort until the activity of the inflammation was much diminished by general or local depletion. There can be no objection to occasional mustard cataplasms, because these leave spaces perfectly free for the renewed application of leeches. Therefore if you suspect that you shall have frequently to repeat the leeches, do not apply a bluter; leave that until you feel pretty certain that you will not have speedily to reapply lecches. Do who I know have imagined that the inflammatory action of the mucous membrane of the stomach may be increased by a blister. I have never seen any such effect. In treating chronic inflammation of the mucous tissue of the stomach or bowels, I have, almost invariably, during some stage of the treatment, used blisters, and without ever having had occasion to regret their adontion.

> As to medicines, if the vomiting be urgent, and there is much irritability of the stomach, I believe that the best thing you can give is the hydrocyanic acid, in doses of from one to two minims every two, three, or four bours, or even less frequently, according to the urgency of the vomiting. lieve, too, that it is useful to combine th hydrocyanic acid, as I did in this o some mucilaginous substance

ceedingly di will often

If I can p purgatives. more especially the nearer the inflammation approaches to the acute form, I rather abstain from them in the early stage, confining myself to the use at the crime; but if obsti-nate constitution takes place, and the injections are not sufficient to produce what you may think requisite, then I would suggest, as the best purgative by the mouth, some jeaster oil. Too frequently, however, that will not be retained, and if so I should prefer a full dose of calomel, combined, per-haps, with a grain of opium; not, however, giving mercury with the slightest idea of its producing a beneficial effect on the inflammation of the mucous tissue. This, I am quite sure, from experience, would increase it; and I would also advise you to avoid opium if possible, because it only tends to starch or grad.

You will remember, too, that during the early part of my treatment in the case of this man, on the second or third day-I added to each dose of the hydrocyanic acid and inucliage, ten grains of carbonate of soda. The acid cructations appear to be caused by a morbid secretion from the mucous and follicular glands, and which secretion, unneutralised, becomes an additional source of irritation in the stomach. The carbonate of soda, then, was given for its chemical effect, and its exhibition was attended with

advantage.

The diet under such circumstances cannot be too simple. Chylification is evidently very imperfectly performed, and it would be absurd to task the stomach with food in large quantities. Nature would soon show the impropriety of it by vomiting the ingesta, with an increase of all the distressing symptoms. If the inflammation be very prge nothing but a little cold water should s small lump of ice placed in the mouth,

2991525C 1 1917A

extends from the stomach into the pharynx. Plain cold drinks, in fact, are most grateful, though, if the symptoms be less urgent, there is no objection to allowing the patient, as I did in this case, a small quantity of arrow-root, or sage, in water. Every stimulant ought to be most carefully avoided. This man himself stated, that everything he took that was "strong," meaning bear or spirits, aggravated his symptoms. You will spirits, aggravated his symptoms. You will find it of great importance to attend to this in private practice. You will frequently be called to cases which will puzzle you to decide whether they really arise from some slow and insidious inflammatory action in the mucous tissue of the stomach, or are merely the result of functional derangement, brought on probably by some intemperance in eating or drinking. Take it as a rule, in which you can never err, that if there is much heat of stomach, much tenderness in produce greater constipation, and when it the epigastric region, and, more especially, is simple inflammation, rather aggravates an increase of heat there on pressure, you that condition. The hiccup (the disphragm will be right in treating the case anti-sympathizing with the stomach) is sometimes very distressing, and you may occar patient from every stimulating article of sionally be driven to the exhibition of opium, drink and food, and applying leeches to the but I am quite sure that you can only give pit of the stomach, or if the pulse warrants it, it, with propriety, as a means of deriving a abstracting blood from the arm. Supposing temporary respite from the distressing effects, that you commit an error in diagnosis, and of the hicrup, which it is far better to endea. that it is only functional derangement (and your tolessen, indirectly, by diminishing the I admit that sometimes it is difficult accuinflammation of the stomach. But supposing opium seems to be absolutely necessary; tient no harm by the restriction of his regithen, before giving it by the stomach, I men, the application of a few leeches, would prefer throwing it into the rectum, and employing counter-irritation; but you in the form of injection, thirty, forty, or may do infinite mischief, under the idea of even fifty minims, in a small quantity of the case being merely one of a weak condition of the stomach, by giving stimulants, and tonics, prescribing carbonate of ammonia, allowing brandy-and-water, advising an increase in the daily quantity of his wine, and permitting him to live a little more " generously.

There was another case admitted at about the same time, in Anne's Ward, which I did not designate as gastritis chronica, but as romitus-cum-hysteria, because I did not believe, though some of the symptoms were present, that it arose from actual inflammation in the stomach. I rather ascribed it to that peculiar irritation of the stomach which we often see in hysterical females; and the mode of treatment pursued, verified, I think, the diagnosis. As considerable pain was complained of (though there was no increase of external heat), upon pressure of the epigastrium, I thought it right to apply some leeches, two or three times, and afterwards a blister. There was here some slight degree of redness at the point and edges of the tongue. e given or perhaps the best thing would but much less than in the man, therefore, as a precautionary measure, I applied the leeches; but I found, after a time, that as a precautionary measure, I applied the leeches; but I found, after a time, that the stomach. The patient there existed so much of that peculiar morphisms are great relief from the bid condition of the sentient extremities of the nerves, which almost universally accom-

panies hysteria, that the same degree of stars suring her is tenderness was complained of ou pressure been subject to over the whole of the abdominal and the neck, eraphical of racic regions. Considering, however, that About two months age a super there might be some insidious inflammation scalp, which had existed for the last two going on, which this would be the best years, disappeared audienty, and since that means of relieving. I applied the leeches, period the child has frequently complained knowing that the loss of a small quantity of pain in the head; she this become dull, of blood could do no harm to a girl in her apathetic, and ceasing to take pleasure in the condition. But the next day, believing amusements of her age. At the same period that there could be no inflammatory ac-tion in the stomach. I ordered her some alternately constipated and affected with creosote, which, upon increasing the dose diarrhers, and became gradually thin, a cirfrom one minim to three, speedily allayed cumstance attributed to jealousy; during the irritability of the stomach. This quite the three first weeks of the month of April of an inflammatory nature, because I never has disappeared within a few days. yet saw creosote taken into the stomach where there was any thing like inflammation existing, without its producing either days; appetite diminished; on the 30th increase of vomiting, or increase of pain, bilious vomitings.

I was, in fact, confirmed in lowing condition :- Face pale and thin; my original opinion, that this was a case of answers only by monosyllables to the ques-hysterical vomiting. I may allude to it tions put to her, and points to the frontal again, in order to say a few words with re- region as the seat of the pain; the eyelids spect to the advantage of creosote-at, are closed, and the patient avoids the light: have myself found in its use -- in gastric af- but can raise up the limbs freely enough; fections.

HOPITAL DES ENFANS MALADES,

BESEARCHES INTO THE DISEASES OF CHILDREN.

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY.

TUBERCULAR MENINGITIS.

Child five years of age, of scrolulous constitution: e, and of mutility; alternation and constiput u; pain in the abde er and to the tomples; blivers to the neck and extremities.—Death; tubercular infiltration of portion of the pla mater; granulations be the aruchould, the please, and the peritonesm.

Cass. - Anne Cammat, five years of was transported to the hospital, from Rue d'Angouieme, on the 30th of April, 1835. The parents of the young child, who mselves enjoy excellent health, and do ant labour under any tubercular affection, inform us that she has never had convul-

at she has & ags of the ophthalmy. mation of the convinced me that the disease could not be the child coughed a good deal, but the cough

April 29th. Constant headache; the prostration is more marked than for last few

May 1. We found the patient in the folet to the degree of advantage which I she cannot maintain the upright posture, the latter do not present any spasmodic movements; the rensibility of the skin is not remarkable, and is equal on both sides of the body; pupils normal; the right is weakened, but still preserved; the face exhibits alternations of paleness and redness; the skin is moderately warm; pulse 72, intermittent; the respiration is slow and unequal, 16 in the minute; the tongue moist, covered with a slight whitish fur; the vomiting has not returned since the 30th; tumefaction and tenderness of the abdomen; constipation for the last four days.

From a consideration of the patient's history, and the ensemble of the symptoms which presented themselves, viz. frontal cephalalgia, sensibility to light, slowness and unwillingness to answer, the stupi 'ity, the diminished sensibility of the integuments, the slowness and irregularity of the pulse and respiration, the constitution, &c., we ventured upon diagnosticating "a meningitis." However, the existence of this affection seemed doubtful to the physician of the hospital, who con-tented himself with ordering an infacion of mallows, and a positive to the abdomen.

During the day the dulness and tendency to sleep persisted; these were interrupted in the evening by low cries; the alternations of flushing and paleness were now well marked.

May 2. Same sleepiness as before answers to the questions we fixed; conjunctive inject the skin obtase; supremer we are conspelled to place strongly before we are

The right normal state; but does not present any hand still continues incapable of moving. marks of ramollissement at any point. We During the day the auctionation seems to cannot discover any tobercle in the sab-progress very considerably. The child has stance of the brain, which was completely recognised her parents; asks to drink, with divided by very thin slices. The pons vaa clear, arriculate voice, and answers several rolli, the cerebellum, and its membranes, are

Chest.-Both lungs are free from adherences with the parietes of the thorax, but underneath the pleura which covers them, we perceive a multitude of small granulations analogous to those found underneath the serous membrane of the brain. In the parenchyma the tubercles are crude and much disseminated; the bronchial glands are also tubercular: the heart and its appendages healthy.

Abdomen .- Several convolutions of the intestinal canal adhere together by means of ancient false membranes studded with tubercles. We observe granulations underneath the serous envelope of the liver, spleen, and intestines in general. The stomach contains some residue of indigested aliment. On the anterior wall we observe the traces of two or three cicatrized ulcerations, round which the mucous membrane is pale and of good consistence. The interior of the rest of the intestinal canal does not present any thing remarkable.

Remarks.-This case presents several circumstances worthy of attention. Let us endeavour to seize the most remarkable. In the first place, let us notice the slow and gradual manner in which the inflammation

hat been pointed out by several writers, particularly by Assacaouses, bitt lay the it was impossible to explain the reason of poles at the time of the often communes and goes on, before the the disease, will fit with the organ.

lowed by billous vomiting on the 30th.

The point of symptomatolog studying extensive

A STATE OF THE STA

creat important of metingitis, and that in conjunction with severe seadache, followed by sympathetic somiting, t is sufficient to make the existence of a naindy which has hitherto remained obscure. Brhaps as much from the inaccurate maner in which it has been observed, as from he real difficulties that accompany its inestigation. In fact, we are not acquainted vith any other disease whose general sympoms simulate those of meningitis, in which his remarkable slowness of the pulse is to se observed.

A third circumstance worthy of notice, was he recovery of the intellectual faculties, and he power of speech, at an advanced period of he disease. This has been pointed out by everal writers, who judiciously warn us igainst being deceived by this apparent imelioration. We have had an opportutity of witnessing this phenomenon more han once, not only in cases where the inlammation occupied simply the surface of he brain, but where the meningitis was accompanied by very considerable effusion into he ventricles.

Finally, we may notice the coincidence of ubercular deposits in all the other great carities. This is an important fact in the hisory of tubercular meningitis. We have sever observed (nor are we aware that any uch case has yet been recorded) an examile of tubercular meningitis, without, at the ame time, finding a deposit of tubercular natter in the bronchial glands, the lungs, he mesenteric glands, or underneath the eritoneal lining of the contents of the ablomen. In two cases we have observed tusercles in the kidneys. This, we repeat, is capital fact. The coincidence of hydroephalus (in our view the same disease as neningitis, the presence of serosity having little or no influence on its march and sympoms in a scrofulous constitution), was long ugo suspected, and even announced, by Drs. PERCIVAL and CHRYNS, and several other if the best writers on this disease; but the ct was never demonstrated in a rigorous oner, until the researches made within he last three years at the Hopital des En-Meledie, by Messru. Gramand of Phi-Rups of Martinique, Constant of establics. Since that period

gitls terminating in death. Nine-tenths of these presented a greater or less trace of tubercular affection of the meninges, and in all there was at the same time a deposit of tubercles in the cavities of the chest or abdomen.

P. H. GREEN.

TREATMENT OF FRACTURES WITHOUT SPLINTS.

TROUGH FOR THE LOWER LINES.

To the Bditor of THE LANCEY.

Sin,-I entertain no doubt that your readers have been strongly interested by the letters on the treatment of fracture, recently published in THE LANCET by Mr. Radley, of Newton Abbott. For one, I freely confess that the simplicity of his statements, and the highly practical character of his reasoning, have excited a very convincing influence upon my own mind; the more to, as I had in the following case, which I submit to you for publication, an opportunity of corroborating, so far as one case can do it, the principle maintained by Mr. Radley, viz that in fractures of the long hones "splints may be dispensed with."

Care. - Mr. Richard Barker, a stout, elderly gentleman, while out with a coursing party near Cove, in Yorkshire, had the mistogtune, in attempting to spring over a dich (not on horseback) from the top of a stakeand-bound fence, to trip, in the act of precipitating himself forward, and fall, with the right leg bent under him. The tibin was broken across, about three inches below the patella, and what was quite as bad, the parts investing the knee-joint sustained such a violent wrench as to be followed by considerable inflammation and an ecchymosis, extending to the hip. He was fifteen miles from home, and extremely anxious to be nursed by his family, but the limb was carefully and skilfully reduced by Mr. Hill, surgeon of Cove, who, probably with a view to keep the limb steady during the journey in a post-chaise, had applied splints, firmly bandaged. I visited him at his own house on the same evening, about six hours after the accident, and found him suffering dread fully. A mattress and bed having been laid on the floor of a small back-room, looking into his garden, he was conveyed there and stripped of his clothes, when I discovered that it was highly necessary, from the amount of heat and swelling, to undo all the bandages, for that night at least; twelve leeches were then applied to the A conserves. Since that period knee, and a gin-and-water holton was discrete a consecutive series of rected to be applied to the smoking-hot limit. These soon placed him in a state of comparative case. The broken leg was merely small matters is no laid in the hollow of a soft pillow, and the for if the creases at foot was kept erect by means of a heavy box, the course of this which affected it. which afforded it a convenient prop.

foot deep, into which was carefully spread a bandage beneath. The sides of the trough kept the foot upright, and in preparing it I tore a piece out, to allow the ham to rest at ease; for the board, in a case like this, must be long enough to come quite up to each side of the knee, and project a few inches beyond the toes, and likewise be so deep as to completely receive the foot and rise CASES OF BRONCHIAL IRRITATION above it. A piece of very strong tape, two yards long, was next passed under each end of the trough, and kept from slipping by holes bored through the upper corners of the mill-board. After the leg had been laid in a this apparatus, the ends of the tape were tied together in one firm knot. A double EXTERNAL APPLICATION OF CROTON OIL cord, running through a swivel-ring that; was made to slide along the iron rod, was let down and fastened to the knot, and the whole was thereby gently drawn up and inch or two, to clear the bedding, and was! Sin, - I transmit the following remarks added what he called his "bridle," viz. a useful journal, and remain, Sir, yours, &c. piece of cord fastened to the trough, and brought across the bed to his hand, so that Castle Douglas, December 18th, 1835. ifter a few days he could steer the whole; concern with great precision.

Mr. B. soon felt the convenience of this. That epidenics are at their invasion more stan; be could turn in bed on either side fatal, although less contagious, than at their vithout affecting the position of the leg and height and decline, is a fact which long oot, and was enabled to ease nature with observation has confirmed. Russel on confort and without assistance. After three Plague, p. 261.) The circomstances, howor four days, by means of a bed-chair, he ever, are by no means universal, as was ould sit up in bed to read and write, take) exemplified in this district during the recent is meals, and wile away the tedium of con-inement. With the exception of a satur-prowling about the country, in straggling line lotion, and loose linen rag placed upon cases, nearly five months ago. These became he upper surface of the leg, nothing more more numerous as the "spidemic conras required, and the case got quite well in stitution" advanced, till at length there was ix weeks, and would have done so sooner, scarcely a family in which some members ad not the inflammation of the knee-loint; were not affected. It was not however until clayed us awhile. The union is so neat on the decline that the disease, which heread perfect as almost to defy scrutiny.

constant and the child in a great mea-per this stack; the child in a great mea-ter to the first-mentioned girl), was seized at a child being much weakened with mearles; but the mother knowing the reach the child codema of the feet disease, as at that time raging, to be of a way inlid nature, did not call medical advice

until the eruption had faded, and the tracheal irritation had fairly set in. The case resembled, as nearly as could be, that of her sister's, only the cough, if any thing, was more severe. As this was one of the first cases of that nature which had occurred. croup was dreaded, and she was in consequence freely depleted by leeches, and other antiphlogistic remedica were employed, by which the tracheal and thoracic symptoms were certainly overcome. But what was the result? When I called in the evening the little patient was fast slipping out of existence, in a low comatose state, with a small quick fluttering pulse. I immediately ordered her a strong becf-tea injection, which was retained about half on hour-This was ordered to be repeated every two hours. After the fourth she began to revive, the pulse got fuller and more moderate, and she was soon out of danger, but the complete recovery was slow. I am persuaded that had not these enemata been used, she would soon have been past all human aid, and that principally from the error committed in mistaking bronchial irritation for cynanche trachealis.

Before concluding, I may remark that children at the breast appear to he less liable to be affected by epidemics than those of stronger and maturer years. This, whatever may be its cause, appears to be a wise provision of nature; for neither could the infant bear with impunity a sharp attack of the disease, nor could the remedies requisite for its removal be employed with safety. The almost invariable answer of a mother, when asked regarding any one of her children which n.ay have escaped some epidenic, when the rest of her family has been attacked,-that "it was suckling at the this occurrence to the period of his decease time."- first led me to notice the fact ; and I find that others also, on recalling to remembrance long-past experience, accord with the truth of the assertion. A brief case or two will suffice to show that there is at least some cause for this observation. The first is that of a woman, who, during the full blush of the eruption of measles, was delivered of a living full-grown child. She had a quick accouchment, and made a favourable recovery. It was her fourth child. Ere the measles had subsided the child was put to the breast, and continued to enjoy uninterrupted health, without even the slightest rubcolous spot.

The next case is that of a Mrs. R., who, having occasion to enter the house of a person labouring under typhus fever, caught the infection, went through the disease, and suckled her infant all the time, which remained unaffected; whilst a little sister, a husband, and a son, were all seized. And there is now a family under my charge, three of whom have been for the last three weeks affected with typhus, whilst the child in the cradle, in the same room, beside them, minated his sufferings in

ANEURYSMS OF THE THORMCIC AORTA.

To the Editor of THE LANCET.

Siz,- I was lately requested to make an examination after death, of the annexed interesting case, the particulars of which, with a few detailed circumstances, in reference to the patient's history, I offer for insertion in your valuable publication. I am, Sir, your obedient servant.

CHARLES J. H. RAY. Tonbridge, December, 1835.

Jeffrey B., atat. 52, of a plethoric, unhealthy appearance, by trade a sawyer, and accustomed to hard labour, in the performance of which he had habituated himself to large drinkings, was, about twelve years since, suffering from a protracted pneumonic attack, that produced a troublesome cough, to which he was afterwards almost constantly subject. With this exception for the following ten years his health was tolerably good, or until he was accidentally struck by a heavy piece of timber on the upper part of his chest, which projected him forcibly against the axle of a waggon, near the centre of his back. At the time, he was informed that no fracture had resulted, but he was bled freely, and attended medically. From he always complained of much uneasiness in these situations, describing what he felt as a constant, dull, gnawing sensation, oftentimes distressingly aggravated. He had persevered in the use of the warm-bath. large doses of iodine, colchicum, and opium, the latter only appearing to be serviceable, by its composing influence. Cupping, also, and many varieties of counter-irritation, had been freely prescribed, but without benefit. From last September his sufferings increased considerably, and during his coughing, small portions of dark coagulated blood were frequently ejected. He was unable to exercise the left arm, to rest on the left side, or in a horizontal position, and could ascend the stairs only with great difficulty. On the whilst exerting himself rather more than usual, coughed up a large quantity of blood frothy in appearance, and of a bei come, which continued for the He was immediately means were adm

two days from the

umstance. Autopsy, 20 hours of the Mark.—The whole body presented extentially, a pale sallow aspect, and appeared elightly distorted on the left side. That side of this class was evidently much disconset, and afforded a solid 1, sonance on percussion, whilst on the right side to football natural. right side a perfectly natural sound was distinct. Immediately on dividing the cartilages of the ribs, on the left side, a large quantity of scrous fluid escaped, and within this cavity was contained upwards of a gal-lon of blood, about one-third of which consisted of firm congula. The superior lobe of the lung on that side had, from the pressure, colinpsed towards its root, but the inferior lobe apparently occupied its usual extent of surface, although so much altered in structure and appearance that it almost entirely resembled the spleen; in its interior was formed a cavity that might have contained two fluid ounces; and the pleura, on its posterior surface, was closely adherent to the body of the descending aorta, near the situation of the sixth rib. From this vessel, between the sixth and eighth ribs, a large ancursymal swelling had existed, which had also become connected to the inferior lobe of the lung; its gradual expansion from within outwards had completely absorbed at least two inches of the seventh, and about half an inch of the eighth ribs. commencing at about an inch from their articulations with the corresponding vertebræ, and the fibrinous ancurysmal coagula were firmly embedded in this remarkable depression. The heart was of ordinary size and appearance, unusually flabby, and per-fectly evacuated. The right lung was healthy. The whole hody of the arteria innominata formed another vast aneurysm, which appeared to commence just before the origin of that vessel from the aortic arch; while its extent terminated at the hifurcation, nearly opposite the sterno-clavicular articulation of the right side. Its size was that of a large orange, and on its anterior aspect the parietes were ulcerated, and irregularly detached, to the extent capable of admitting a small egg. This large fissure was in immediate contact with the sternum, and from a mutual pressure had caused a considerable absorption of its substance, centred by two deep and distinct depressions, either of which was capable of admitting a sixpence, and near to the sterno-costal articulations of the first and second ribs on the left side. On exempting to raise the sternum, after a division of the cartilages, it was broken gransversely in this situation, and exposed carfout state of the surrounding bony The abdominal viscera were ge

INJECTION OF THE NITRATE OF SILVER

IN

GONORRHOEA AND LEUCORRHOEA.

To the Editor of THE LANCET.

SIR,-Having been the humble means of introducing to the notice of the profession the nitrate of silver as a local remedy in leucorrhos and gonorrhos in the female, and being interested in ascertaining whether the experience of others was likely to confirm the opinion I had entertained of it, I felt great satisfaction in observing so favourable a report as that contained in your journal of last week from the North-London Hospital. Dr. Elliotson, in his clinical lecture on a case of gonorrhea in a female, when speaking of astringents and specifics given internally, remarks, "There is, how-ever, a local application which is, I believe, recommended by many practitioners,* and which has, I think, by far greater power over gonorrhoa and leucorrhoa than any other local application, where there is no inflammation, and that is the nitrate of silver."

I shall make no comment on the above passage, except to observe that it affords me much pleasure to find the remedy favourably spoken of by so distinguished a member of our profession as Dr. Elliotson. My principal motive in addressing you, is to remark on the exceedingly weak solution which Dr. E. says he begins with, namely a quarter of a grain to the ounce of water. I need scarcely observe that I have used the nitrate of silver in those diseases of females in a variety of forms, and I have never found a solution of three or four grains to the ounce to create any painful sensations which have induced me to discontinue its use, or even to diminish its strength, unless, indeed, there existed excoriations, or a highly inflamed state of the parts; and as an instance of the extent to which its strength may be increased, I may notice the fact of a patient now under my care who has used it for a period of three years, in the proportions of seventeen grains to the ounce of water; this being the only remedy which has kept leucorrheal discharge in check, and which I have no doubt has arrested the progress of organic change.

Permit me to suggest the necessity of avoiding the common pewter syringe, as, when used, a decomposition in the solution takes place. The short straight syringe I consider quite a uscless instrument. The ivory or bone syringe,—my invention some time ago,—and which may be purchased at

In a clinical feeture, published in TRE LANCET of Aug. 11, 1832, Dr. Ellioteou ascribed the proposal to employ this astringent in vaginal discharges, to Dr. Jewell.—Eb. L.

most of the surgeous' instrument-makeses (in the sale of which I have no interest, direct or indirect), will, I think, be found, from the material and shape, a convenient and efficient instrument, and may be used for injections of any kind. I have the honour to be, Sir, your obedient servant,

GEO. JEWELL. Sackville-street, Dcc. 22, 1835.

OBSTRUCTION OF THE NOSTRIL.

To the Editor of THE LANCET.

Sim,—I shall feel obliged if you will insert the following letter, and the remarks which I have subjoined to it, in your journal. The letter is addressed to me as the history of his case, by a patient. I am. Sir, your obedient servant,

S. PLUMBE.

Southampton-street, Dec. 14, 1835.

"Dear Sir,—As it appears that my case may possibly be instructive, I beg to hand you its history up to the time at which I consulted you. Previous to the attack which it describes, I had served during twenty-four years in India, and had never experienced severe illness of any kind.

"Shortly after a trip to Brighton, in August, 1834, I experieuced a sensation of cold in my nose, with a catarrhal discharge, which soon afterwards became thick and offensive, causing me much annovance. In December it became much aggravated, and in the subsequent May a partial obstruc-tion of the right nostril took place, and increased daily. Shortly afterwards the left nostril became similarly affected for a short time, though only at intervals. The right nostril now speedily became quite impervious, and I found myself unable to draw air through it, or to expel air from the lungs by that passage. I experienced also great pain over the root of the nose, in the direction of the frontal sinuses.

"At about the latter end of May I consulted a surgeon at Brighton, and afterwards sought advice elsewhere, without any favourable result. I was recommended by one to use an injection of nitrate of silver, and by another to try one of tincture of kino, and a variety of other similar applications, all of which I patiently tried without effect. Other surgeons assured me that the constant sanious discharge from the mostrils, which accordated my upper lip, and which had rendered me uncomfortable in society to an extent which I am hardly able to describe—night be got rid of by treating it as a gleet affecting the mucous membrane of the attent. The rid and the recovered within a factor of the latter than the latter

locally and inlocally and inlocally and inlocally and inuse the golden definition, and to thrust it up
the nostril by means of a camel-hair pencil; and, as a last resource, to give a trial to
the injection of chloride of sods; and,
finsily, with the lope that the disease really
existed in the infrusing had made up my
mind to the extraction of a molar tooth.
Ses-side leisure and pursuits did me no
good, either as regarded my general health
or the local affection. I am, your obedient
servant. C. S.

"To S. Plumbe, Esq."

Remarks .- The case of this gentleman is, so far as my experience goes, one which the profession will consider rather singular and instructive, for although suffering for so long a period, the sequel is, that by the most simple means he has been restored to a state of perfect health, in the course of a few days. On examining the nasal passages, I found the right perfectly closed by the contact of the Schneiderian membrane at the point of union of the vomer with the cartilage and the alæ, with the ossa nasi, a fissure presenting itself there, instead of the open nostril. A probe was introduced on the first day, with some pain. On the second day a small pledget of lint was passed through an eyed probe, and introduced, with a little pain, and some blood was discharged. quantity of lint was increased from day to day, and, finally, the probe reached the throat, and gave the opportunity of applying the black lotion to a part of the ulcerated surface. The day after, the probe passed into the throat, and, to use the patient's expression, "hurt the root of his tongue." He could then pass a little air, by great exertion, through the nostril, and some minute flakes of curdy matter were blown out. The sanious discharge continued for two or three days, the nostril being still half obstructed, when the patent, by a forcible effort, expelled a large mass of curdy matter, which I take to be the inspissated pus, - the ulcerated surface having been pouring out a healthy secretion of matter, but the passage before and behind having been so closed as to prevent the egress of any but its most finid parts. Whether this view of the case be correct or not, a very large lump of the substance described was blown out little effort, into the patient's handkerchief, and he recovered within a fortnight, by the application of the black lot camel hair pencil. Toe rig

OUNDS AND

BEMARKS ON THE REPORT OF THE DUBLIN COMMITTEE OF THE BRITISH AMOCIATION.

To the Editor of THE LANCET.

* Sin. -The committee, appointed by the British Association for the Advancement of Science to examine into the nature of the heart's movements, and the causes of its sounds, have, after a series of experiments, arrived at some conclusions which are confirmatory of views which I have long since advocated in the pages of THE LANCET, and at other conclusions which are at variance with those views, and which I have been induced to quote and comment upon, from a desire to arrive at truth on a subject, which, to use the words of the committee, " from its importance, whether in a practical point of view, or as an object of philosophical inquiry, is deserving of further investigation.

The following quotations are from the report of the committee, as contained in the Dublin Journal for September 1835.

Section 3 .- Conclusion 5 .- If the interval between two successive beats be regarded as divided into four equal parts; two of these parts may be allotted to the duration of the ventricular systole."

A similar opinion was advanced by Lacance, and since by Dr. Hope, but it has met with unanswered objections in THE LANCET of January 12, 1833, which contains the detail of an experiment by which the time from the commencement of the first sound to that of the second sound was carefully measured, and found to be a fraction less than one-third of the time, instead of two-fourths, as maintained by the com-

" Conclusion 6 .- The ventricles, in their systoles, approach the front of the thorax; and, by their contact and pressure against it, produce the impulse or beat of the heart.

In the natural state of the parts the ventricles must always remain in contact with the parietes of the chest, and can neither recede from nor approach them. If the ventricles did recede from the parietes, they would cause a vacuum between their anterior surface and the parietes; and this is so much at variance with physics and common sense as to be untaliets on the heart's motions have not ted the effect of outting away a por-

reposition, and without making any litered the mechanical relations of those parts whose motions they were about to examine; except as regards duration and succession, we might as well examine into the manner of the progression of an animal, having previously broken one of its legs, and set down its awkward gait for natural movement.

If the above-mentioned alteration in the mechanical relations of the heart, and of the parts which enclose it, were allowed for, the results of their experiments would, I think, agree entirely with my description of the heart's movements contained in THE LAN-CET of February 8, 1834.

" Section 4. Conclusion 3 .- That the first sound is connected with the ventricular systole, and coincides with it in duration.

That the first sound is connected with the ventricular systole had been long established: but that it is of equal duration will not, I think, be generally admitted; particularly as that duration is stated by the committee to be two-fourths of the time of one beat, in which case the duration of the heart's first sounds would be twelve hours out of twenty-four.

"Conclusion 4.- That the cause of the first sound is one which begins and ends with the ventricular systole, and is in constant operation during that systole.

On what ground is it stated that the cause of the first sound is of equal duration with the sound itself? There is no necessity for this. The sound of a drum is of longer duration than the blow which caused it; a barp-string vibrates long after the finger has struck it; and though the shock of the sudden tension of the ventricular valves be instantaneous, yet the vibrations excited by the shock of sudden tension may

" Conclusion 7 .- That it is produced either by the rapid passage of the blood over the irregular internal surfaces of the ventricles, on its way towards the mouths of the arteries, or by the bruit musculaire of the ventricles, or by both these causes.

Passing over the inaccuracy of stating the bruit musculaire to be the cause of the first sound-i. e. one sound to be the cause of another, I have merely to observe that the muscular sound of a powerful muscle bears no comparison in loudness to the heart's first sound; and if the passage of the blood over the internal surface of the ventricles be the cause of the sound, why does not the entrance of the blood during the diastole of wordy, of a moment's consideration. In the ventricles cause a similar sound? For the ventricles cause a similar sound? For their deductions, the different experiments to it remembered that the Committee state the duration of the systole to be two-fourths of the time of one best; and, consequently, on of the cavity containing two-fourth only remain for a free supply from the auricles. Then, in both cases, the g one of the terms of velocity of the blood being nearly equal,

why attribute a sound to the exit of the abrupt and strong a blood over a comparatively smooth path, tenaion of the value blood over a comparatively smooth part, when its entrance over a comparatively rough path causes no sound. Both of the above explanations are at variance with analogy, and they are equally so with pathology, for the loudness of the sound is, cateria paribus, in the inverse ratio of the quantity of muscle; and when a bruit is heard, consequent upon the passage of blood over the surface of the ventricles, or of their orifices, the sound is so different from the true first sound, that it has become a diagnostic mark of functional or organic derangement of the heart.

The experiments of the Committee afforded no results which at all invalidate the opinion that the heart's first sound is caused by the auriculo-ventricular valves, and the only argument they advance against that opinion is contained in the following con-

" 5. That it does not depend on the closing of the auriculo ventricular valves, at the commencement of the systole; because such movement of the valves takes place only at the commencement of the systole, and is of much shorter duration than the systole."

The conclusions of the Committee afford, throughout, evidence that they consider the first sound of the heart to be a continued and equal sound; otherwise there has been a great omission in their not having stated the instant of its greatest intensity.

The nature of the first sound is, however, a matter for the ear to determine, and not for argument; but I think I shall be generally supported in the opinion that it is an abrupt sound, and not continued and conal. as described by the Committee. If it be a continued sound, how could Magendie have supposed it to be the result of a blow, or an impulse of the heart, against the parietes of the chest?

My answer to conclusion 4 applies equally to conclusion 5; and I have merely to add, that the first sound occurs at the instant in which the valves close,-that the closure of the valves inevitably causes sudden tension of the valves, -that the sudden tension incvitably causes vibration of the valves, -and, therefore, as all sounds consist of vibration, and as no sound can exist without vibration, nor (within certain limits) any vibration exist without sound; and as, in the healthy heart, there occurs no phe-nomenon which is calculated to produce so

tion as the sudden from these facts and, Dam led ribute the sound to your obedient ser rant E. L. BRYAN.

London, Dec. 16th, 1635.

LONDON PHRENOLOGICAL SOCIETY.

SKULL OF DEAN SWIFT.

Ar the second meeting for the session of this Society, a paper on the skull of Dean Swift was read by Mr. J. I. Hawkins. This skull was examined at the late meeting of the British Association at Dublin, and became the subject of an article in the Dublin Phrenological Journal, and other periodicals. Mr. Hawkins, on the present occasion, examined some points of debate which had subsequently arisen respecting it, and endeavoured to show that the real character of Swift was in accordance with the phrenological developments of the skull. The character of Swift in domestic life, and as an author, seems by many persons to have been greatly misunderstood; and amougst other individuals who made the examination of the skull a subject of ridicule against phrenology, was Doctor Macleod, one of the lecturers of St . George's Hospital, who adopted the vulgar belief respecting Swift, and strove to show either that phrenology had no foundation in truth, or that the skull was not the skull of Swift. As Doctor Macleod professed to be a medical man, Mr. Hawkins (probably on that account! took up his remarks, and allowed other writers to be answered in the reply which he had to give to the comments of the editor of Messrs. Longman's periodical.

The question respecting the identity of the skull was indisputably settled by Mr. Hawkins. Swift, being a dean of St. Patrick's, was buried in that cathedral. short time since, some alterations were made in the edifice, which caused the exposure of the coffins of Swift and Mrs. Johnson, his " Stella." The circumstance coming to be known to Dr. Houston, of the Dublin College (whom Dr. Macleod describes in his pamphlet as a "buzzing busy-body") Dr. H., with "impertinent curiosity," as Doctor Macleod declares, helped to "ransack the coffin," in order to find "a stumbling block for himself and other fools." This " worthy," continued Doctor Maclood, then displayed his "deplorable ignorance and on finding that the skull was a mall one, by suggesting that the "meetal how-ers" of Swift srose from "diseased ac-tivity." (Mr. Hawkins in his paper and "that he remembered no falling from Dr. Houston vate examination of

found in the skull examined at Dublin :-

" Amativeness, large. Philo-progenitiveness, large. Lave of Approbation, very large. Benevolence, small. Ideality, small. Wit, small (skull thickened here). Imitation, rather full. Number, moderate. Language, large (skull very thin). Comparison, moderate. Consolity, moderate (skull thickened)."

In opposing the views of the anti-phreno-logists Mr. Hawkins drew a character of Swift, which tended to show that his actual propensities and faculties were very different from those described by his opponents, and that they were, in reality, in very exact accordance both with the developments described in the above list, and with the fullowing account of other organs measured at

Individuality, very large. Order, full. Form, large. Weight. full. Eventuality, full. Time, moderate. Locality, large.

"The average of all these," said Mr. Hawkins, "will evidently warrant the opinion that, at the lowest estimate, the term rether kerge, should be applied to the instellectual indication, the lower perceptives being early kerge, and the reflectives mediate the control of the con kins in contradiction of a statement which far from exemplary. Destitute of temperature became current, that the intellectual deve- and magnatimity, and, we will add, of price lapments in the skull were very small, as ciple in the former; and, in the latter, compared with those which might have tenderness, fidelity, or compassion." head expected in the head of such writer. Respecting Swift's love of supershapidit, M as Swift. Amongst the hidgraphers of Swift Hawkins said..." I was informed in Dublin referred to by Mr. Hawkins in his estimate as a notorious fact, that in a fit of heads of Swift's character, is "the learned Dr. lence, the Dean lent small sug Beddoes, who, in the ninth every of his to several poor men, with work, entitled 'Hygeia.' has sacribed the that it might be said, vertigo, with all its distressing consequences, I that shortly afternation

indulgence; and he a early and pro e conduct towards the anti-phrenologists to have been remark-shy great, and his "Gulliver," his "Tale flamed imagination, and the exhausted of a Tuh," and his "Battle of the Books," frame, of a premature voluptuary, who still were pointed to in evidence. His powers of courses alegaries, which he was unable to imitation they declared to have been very enjoy." The constraint appropriation Dr. Boldocs enjoy." The could specialism Dr. Boldoce was disposed to derivations the tone of gross nal of all authors. His power of language indelicacy, of which Swift's writings afford they considered also was extremely limited, so many proofs. Mr. Hawkins also ob-because he "seldom used any but his verna-serves that in his biography of Swife, at cular tongue," and employed words only as page 343, Sir Walter Scott, speaking of the "a means to an end." His faculties of impure tone of conversation prevalent in comparison and causality they regarded as Swift's time, says, "Although Swift's offences remarkably great, on the ground that he of this description certainly far exceeded was " the finest and most subtle reasoner" those of contemporary authors, the peculithat ever entered the field of politics or arities of his habits and state of mind are ntroversy.

These opinions were placed in array by grossness." Again,—"his delicacy must have the anti-phrenologists against the following been only occasional and capricious, for his extract from the table of the developments journal furnishes many instances in proof of how little that delicacy influenced his own correspondence with females.

ter days, to hable

Mr. Hawkins also quoted the following passage from Dr. Barrett's Essay on the Life of Swift, to show the gross animal pro-

pensities of the Dean:-

" Nothing is more observable in the true and undisputed productions of Swift, than the pains which he seems to take in raking together the most nanseous ideas, and dwelling upon the most indelicate images. It is unnecessary for me to bring examples of this strange propensity of his nature; which is the more serviceable to us, because he is almost singular in this respect, and it forms the strong outline that distinguishes him from almost every other writer. In a pamphlet which came out in 1704, called Some Remarks on the Tale of a Tub, he is similarly described."

With regard to the extent of Swift's benerolence, Mr. Hawkins observes that Mr. Jeffery, in a number of the Edinburgh Reries for 1816, says of the Dean:-

"He was neither a very dignified nor a very amiable person. The truth is, we think, that he was extremely ambitious, arrogant, and selfish; of a morose, vindictive, and haughty temper; and though capable of a sort of patronizing generosity towards his

I WAS I SHOUL

eveners, he in legal proceeding against the whole against the whole of them, against the whole of them, against the whole of them, and their into fits best grammatical arrangement, and families." Book also says that in Swift's latter days he was "moody, melancholy; if he had been writing in prose." and ill-humoured, and a biglists on all occasions." In reply to the latter of the swift's was a man of gram self and imagination, and had little immetation, Mr. Hawkins in vain presented to the notice of Swift." and had little immetation, Mr. Hawkins in This fact, said Mr. Hawkins in direct quoted first, the remark of Dryden on receiving some poetical exercises from Swift, -" Cousin Swift, thou wilt never be a poet," which Swift never forgot, or pardoned; and, secondly, Mr. Hawkins referred to the following remarks by Scott :-

" He never attempted any species of composition, in which either the sublime or the pathetic was required of him. But in every department of poetry, where wit is necessary, he displayed, as the subject chanced to require, either the blasting lightning of satire, or the lambent and meteor-like corruscations of frolicsome humour. We look in vain, in his writings, for depth of feeling or tenderness of sentiment; although, had his friends. such existed in the poet's mind, the circumstances must have called them forth. The is, in short, a kind of poetry which affects wither sublimity nor pathos." Again,-"Yet this grandenr is founded not on sublimity either of conception or expression, but upon the energy of both; and indicates mood of passion, rather than from poetical And, to combide the extracts on this head, - " But Swift, without ever trespassing into figured or poetical capressions, good set phrases always at his command, and displays a sort of homely richness, like the plenty of an old English dinner, or the ments; but was in the highest degree favourable to the effect of his humour, very much of which depends on the imposing gracity with which it is delivered, and on the various turns and heightenings it may receive from a rapidly-shifting and always appropriate expression.

Respecting the opinion that Swift ought to have had, from his faculties, the organ of language very small. Mr. Huwkins quotes Walter Scott the following pas-The government of Ireland his alwayence as much as his ain,—" His powers of versi-bly adapted to his favou-which is a handouff tabo is master of his

Last wears as a bracelet. Swift was of the latter description; his lines fall as easily

his organs of comparison and causality." In concluding his argument against the repeated declarations "that the character of Swift was the very opposite in every respect to the description given of his skull by the phrenologists, Mr. Hawkins said-" It may be remarked that Swift's very large individuality and form, large size and locality, full weight, eventuality, and order, will account for all his extraordinary powers of discrimination; and his very large secretiveness, destructiveness, and combativeness, combined with the above, would give that causticity to his satire, which made him such a pest to

We need not farther extend our extracts. We have suffered the subject to occupy so nythological fable which conveys the com-plinents paid to Vanessa, is as cold as that the skull of Swift has furnished, through addressed to Ardelia or to Miss Floyd. It misrepresentations and want of information, the most important occasion that has offered for many years to the enemies of the doctrines of Gall; and because, while the science of phrenology is one of great interest to medical men, too many of them have rather ardour of temper than power of not time to examine the facts on which it is imagination. Facit in liquatia versus. The based, for themselves. We do not, ourselves. elevation of tone arises from the strong hold with many of the opinions that are entertained by its disciples, but we cordially concur with Annaat, in the general opi-nion expressed by him in a late address which he delivered as president of the or ever employing a word that can be called Phreuological Society of Paris, at the anfine or pedantic, has a prodigious variety of hual meeting of the Society. A brief notice of the discourse appears in the Edinburgh Phrenological Journal for Dec. 1835 :-"In this discourse," says the editor of the wardrohe of a wealthy burgers. WESTMINSTER MEDICAL SOCIETY.

Salurday, Dec. 13, 1835.

Mr. RICHARD QUAIN in the Chair.

PCTEMA.

Da. Apprean exhibited several was casts this evening in order to illustrate the different forms of eczema. The Doctor congratulated the members on the fact that medical men were now paying that attention to the disease which it well merited and required, for the ordinary forms of the disease had hitherto been much neglected, indeed, he feared, treated with contempt; and the same with cutaneous diseases generally, although there was no class of diseases so little understood, and none more likely from a wrong Cagnesis to affect the reputation of a me food wen. He still maintained that the work of Willan and Bateman contained the description of Mr. Thompson's case of eczems, with the exception of the exquisite form of exfoliation. As to resication existing in the case, he had not the least doubt of h, as it oftentimes required the greatest attention to ascertain, and might escape notice therefore. He did not doubt, in fact, that it was frequently overlooked. Why the exfoliation had proved so exquisite, he presumed, was owing to the vesication not terminating with equal being fully developed, and occasioning an Dr. Apparam, finding on of fluid between the cuticle and the

te rors, causing if s tostend of the almost invariably ikin. Dr. Cop have led to the accumulation of facts and found on the introduction of the filling up of details. But if phrenology and had, with his usual actions, mentioned be true, do not concern yourselves about at the last meeting the presence of gastroist future success, for there is no cample enterite with eggents, but he (Dr. Addison) of an important truth once fairly launched, having failed to make its way. It must, broadned the others is generally some from local irritation, and was benefited by some must be until to inconvenience in the state of the one must be put to inconvenience in its arsenic and other irritants, which would *progress, and few people are fond of being not, he thought, he the case, if eccema were set aside. Dr. Apprison replied that the statements the isual period at which attacks returned, and in one case described by Bateman they returned every month for a considerable period

Mr. Thourson said that had any student referred to Bateman's description of cerema ruhrum, he would not have recognised the similarity between it and his 'Mr. The case. It was far from his intention to depreciate the merity of those authors. Since the last report the antiphlogistic treatment had beer persevered in, and the patient had with benefit been blod twice; the blood was copped. The subject here dropped.

Dr. Jourson Informed the Society that it had to regret the less of another member Mr. Marti, who had been carried off very and lenly by hemoptysis. He was sen for to see him, on Priday, at seven a m., it consequence of the hemorrhage, but was no able to attend until five p.m. In the mean time Mr. Lambert was requested to see his and he bled him. The blood drawn wa cupped, the first hemorrhage did not ex eced a cupful, and throughout the day th sputa was only tinged. At his (Dr. J.'s visit, the pulse was somewhat accelerates the secretion becoming more florid, an the cough more troublesome. The friend said that the patient had had a slight cong for two mouths, with but little expectors tion. He ordered a grain of lead wi a grain of opium. The bowels were lar, but shortly after one dose was the bleeding returned, and prove sine p.m. flad any as

-

waived giving an q times found to een aneurysmal.

Mr. Thompson detailed a case which terminated as rapidly, the autopsy displaying an immense vomica, satisfactorily accounting for the result. A slatter cause might be

developed in the present case.

Mr. Howne considered it but right to inform the members, in case an opportunity of ascertaining the truth should not be granted. that when he was requested to see Mr. Mart a short time back, it required not much difficulty to discover that his end was fast approaching, and of this he (Mr. H.) informed his friends accordingly; Dr. Clarke, also, under whose care he was from the beginning. had given no hopes of him.

Mr. LAMBERT declared with warmth that Dr. Clarke had not given any such opinion, but quite the contrary, and he (Mr. L.) also believed that his lungs were not affected.

Mr. House intimated that there were gentlemen present who had heard the diagnosis of Dr. Clarke expressed, and Mr. DAVIDSON said that Dr. C. certainly had i considered his case irremedial.

MEDICAL MAGNETISM.

After some further remarks from Mr. Verrall, and Drs. Stewart, Webster, and Bhindell, Dr. Chowne requested Mr. Thompson to report the progress of medical magnctism since the last discussion on the sublect.

Dr. Schnipt first satisfactorily explained to the Society how Dr. Faraday's name had been used, although not by Dr. S. himself, and also alloded to the statement made by Messes. Watkins and Hill, who it appeared had now authorized Mr. Davidson to disown on their part all knowedge of the competition | in magnets. Dr. Schmett said as we understood him that Mr. Wilkinson of Pall Mall was delegated by Lord Scareshoro' to make the proposal before stated to those gentlemen, that it was accepted by them, and that their failure was attributed to the inferiority of the English steel.

Mr. HALE THOMPSON now stated with regard to the question whether the magnet could produce physiological effects on the human body, that he must answer "yes!" although Dr. Ritchie had denied the posshiftiy of that result. As to its remedial efficacy, the time, he believed, had not as ret been sufficient to allow an opinion to be dat the Ophthalmic Institution. From Chara of amaurosis presented to Dr. Course were selected, but these were selected, but these were selected without their faults; in all gras produced, and great mo-But this afternoon, pairy in lending his

manner in wi

rating, he (Mr.T.) had certainly produced a more decid ed physiological effect, by magnetizing a boy, who was received into the Westminster Hospital, with concussion of the brain. The pupils were dilated, and on first applying the magnet for three minutes, contraction followed, and on again employing it for five minutes, the same phenomer occurred, to the complete satisfaction of himself and Mr Snowden, a gentleman who had acted as house-surgeon to several hospitals. He thought it right to state, that unknown to Dr. Schmidt, he had been told by Mr. Weiss that he could not undertake to make magnets of equal power to those of Dr. S.

Mr. Hour stated that his daughter, who had been deaf for many years, and who had been placed in the circle of the magnets five times, had derived considerable benefit

from their employment.

Dr. WEBSTER remarked, that out of the four cases which he had witnessed at the Eye Institution, only one received beneat; that of a lady, who affirmed that she could see much better after each application, all other remedies having failed to afford her any relief. In the second case the man saw The other two received no benefit. worse.

The Passident, before adjourning the meeting, remarked, that it was no unusual thing for amaurotic patients to say that they saw better after any new application was made.

THE LANCET.

London, Saturday, December 26, 1835.

Depurers from the medical schools have been visiting the CHANCELLOR of the Excurquen during the past fortnight, relative to the establishment of the new University. We hope that the whole of these bodies are satisfied with respect to the liberality of the scheme.

Still the draft of the proposed CHARTER is not before the public. Nothing, however, shall induce us to believe that the mambers of a liberal Government will shrink from placing before the community that document which it is their intention to convert into a law, by obtaining for it the sign manual of the King. The institution of the Metropoliton University will constitute an important d his mode of ope-lepoch in the annals of the literature and

science of England. It will also affect in great measure, the immediate interests of a Poor law Commi scholastic establishments in and near London. The conduct, therefore, of the whole business should be as open, candid, and straight-forward, as the object sought to be accomplished is prudent, enlightened, and national. We repeat, however, that there will be no protection against the perpetration of what is unjust, unless a draft of the intended charter be circulated for the inspection of the public.

WEAT species of folly or cruelty can be practised which would not find defenders? A correspondent, who has most unwittingly adopted the signature of "PHILO-HUMA-NITAS." maintains that the charges advanced by the profession against the Poor-Law Commissioners and the Boards of Guardians are not well founded, or justly advanced; and the writer attempts to establish the accuracy of his position, by referring to the willingness with which medical gentlemen have agreed to become parties to the contracts in the Unions, and by referring also to the powers which the Commissioners can by right exercise, in conformity with the conditions of the Poor-Law-Amendment Act. Suppose we concede all that our correspondent has adwanced. - suppose we allow that the Commissioners and Boards of Guardians possess a statute right to treat the memhere of the medical profession with disrespect, with harshness, nay, with cruelty.-suppose also that there are a set of mercenary adventurers, who, having no feeling for the character of the profession to which they unfortunately belong, are willing to sacrifice every other object to the promotion of their own sordid and base propensities, -suppose, we say, that all this

the Guardians large body of individuals, the conductors of and the public, assume at other aspect? Does it present no wider view? Why "PHILO-HUMARITAS," and other writers of his intellectual stamp and caliber, in the blindness and the zeal, or in the muddymindedness of their folly, appear to forget the sole-the only object for which the poorlaws were instituted, so far back as the days of ELIZABETH -that of affording succour to the necessitous sick poor. This is an item in the account, which some of our hot-headed, over-zealous disputants will do well to include. The appearance of such a statement may be displeasing to the calculating political economists, and to the more philosophical, but still less generous utilitarians; nevertheless, it is unite certain that the mass of the English community, and, it is to be hoped, a majority in both Houses of the Legislature, will never forget that poorlaws were instituted for the protection of the poor, and that to such protection the poor are as much entitled as is the first lord in the kingdom to his landed estate. On a subject in which the feelings of human. ity so strongly and convincingly admonish the mind that all attempts at mystification must fail in accomplishing their object. assuredly the people of this country-of course we refer to the rate-paying peoplehave not become so brutalized as to merge every question of human suffering occurring amongst the poorer classes of society, into a mere matter of pounds, shillings, and pence -in short, of setting up a saving of five shillings on the one hand, in comparison with relieving an afflicted fellow-creature from five days, five weeks, or five months. of bodily torture on the other!

> Admitting, then, that the Commissioners and Boards of Guardians may, by lage ex cise the right of giving to a medical titioner the smallest coin in the the treatment of the sick of twenty or thirty.

> that the moral o

F It would be useless to insert the note of " PHILO-HUMANITAS," as he attempts to prove no more than what we have, for the make of argument, just conceded to him,

2 pervertis object, which the provisions of no partiamentary statute ever can, or ever did, recognise.

When, therefore, a medical practitioner is insultingly offered a sum of money which is, confessedly, notoriously, an inadequate compensation for the labour which he undertakes, the executive authorities of the Poor-Law Amendment Act thereby virtually disregard the necessities and agonies of the afflicted poor, and they convert an Act of Parliament into a piece of insolent mockery. If the contract system, screwed down to the very last turn, be so exceedingly efficacious in the case of medical practitioners, why would not the same system be equally efficacious in fixing the salaries of the Commissioners and their worthy assistants? This branch of the subject must be mentioned in Parliament. It is really a pity that the Commissioners should be shut out from benefits which they so liberally bestow on other individuals. Why should they be encumbered with two or three thousand a year, when other persons might be found, caually connetent to discharge their duties. for five hundred pounds per annum? If the contract system is to be pursued, let it be carried out to all functionaries throughout every department of duty in the new

In making contracts with medical practitioners, every person, who is not utterly callous-hearted, will at once admit that the most scrapulous attention should be given to the means which the surgeon may possess of fulfilling the engagement which is enjoined upon him by the moral, as well as the written, obligation of the law. If the Poor-Law Commissioners could but behold in many, ay in most, country parishes, the stitute, poverty-stricken, wretched hovels ibited by the claimants on parochial

PARKET S

4.454

shut out from them their only source of hope and comfort in the hour of bodily affliction and mental agony. missioners may state, perhaps, that they are uninformed on these subjects, and that they consider that their duty to the rate-payers, as well as to the poor, is best discharged by ratifying, in all cases, the lowest tender which is offered by any medical practitioner who has received from one of the public bodies a legal qualification for undertaking the duties of his profession. In such a consideration there is plausibility, but no humanity. On the contrary, as the Commissioners must know, it is not in the power of a surgeon to attend and do justice to many hundreds of poor persons located over a surface of many miles in extent, for a sum of money, amounting, in many cases, to not one shilling a head for the medicines and attendance awarded to each individual. A thrill of horror darts through the blood, when reflecting, only for a moment, on what must be the consequences, the fatal, direful results, of such a nefarious engagement. With a practitioner thus employed there can be no alms giving; he evidently is not in a condition to afford extra-official aid to the miserable objects of the law's solicitude. He must indeed bimself stand in need of that very assistance which he is made the ostentatious puppet and instrument of giving to others, or he would not, he could not, allow himself to be a degraded tool in the hands of men who appear to be ever occupied in working out the double purpose of destroying the poor, and accumulating insults on the members of the medical profession. The Commissioners and the Boards of Guardians ought to know that the mere testimonial of professional qualification is not a sufficient voucher for the character of that surgeon who undertakes, by contract, to furnish every requisite medical assistance to the parochial poor. Knowledge and skill in such gould descrive universal execus- a case are not all that is required; there are from the sufferers the principles of honour, moral attributes, of the said roceive, -if they existence of which the most undoubted and

positive testimony should be obtained but thousands of helpless creatures are placed at 1 the disposal of his tender professional mercies. What evidence of moral character contractors in the Unione are called upon to have the Commissioners and Boards of exercise their curative functions upon not Guardians demanded and received from the only the most introduct, and most impovemedical adventurers with whom the con- rished, but also the least Mormed, portion tracts have been ratified in the Unions? of the English community, too much stress The mentionen of the office in Somerset cannot be laid upon the dependence which, House will be called upon to place copies of in such cases, is necessarily reposed upon these cortificates before the Legislature. If, then, it be confessed that the payment,

indeed, not only offers to obtain money under false pretences. but at the expense of the welfare, may the lives, of the allies afflicted portion of his fellow-creature Buch a man must carry the stamp of cruelty upon his brow. There can be no mistaking the characteristic features of such a being. He knows that in cases of fever, of inflammation, of visceral disease, he may neglect his patient with complete impunity; with complete impunity we say, because the mercenary brute is insensible to the throcs of conscience. In the eyes of the relatives of the victim he stands expnerated from censure, even from accusation, because they are incapable of forming a notion of his guilt. They know not how often the visits should be made,they know not the medicines which should he administered; the practitioner beguiles them with a soft assurance, with a smile of affability, but both emanate from the sanguinary spirit of a vampire.

Nothing can be more narrow-minded or unjust, than to regard the subject of medical contracts in the unions, as being exclusively a medical question. It may suit the purposes of factious and designing writers to restrict the limits of the inquiry within that narrow compass, but we can tell them that I it shall be viewed upon a basis not less capacious than are the boundaries of Eugland and Wales. It is strictly a notional auestion, involving many of the noblest principles of humanity. As such, we shall again and again discuss the subject in the pages of this journal, and as such we firmly believe that it will be fully considered by a henevolent executive Government, and an enlightened Legislature.

Model in Wax, coloured, of the Otic Ganglion and its Neighbouring Parts. Published by

Transport and a second second second

tely beautiful representation conventing part of heman in all but a portion of nature itself. The initiation is so doose, so sipnally striking and true, that the mind is unavoidably turned from contemplating the obvious purpose of the design, to dwell on the marvellous skill of the artist. So nearly animate is the model, that we might almost suppose it to be traced by the hand of Prometheus. Criticism on the production must consist wholly of praise. A more perfect work of art of this description was never submitted to the inspection of the profession.

THE LATE DR. TURNER.

[From an Edinburgh Correspondent.]

All the members of the profession bere deeply lament the promature death of Professor Terrial for although he was not one of those brilliant stars whose rays have materially contributed to illuminate the dark paths of medical science, and his fame as a lecturer did not add much to the removal of the University, yet he was a man of considerable intellectual acquirements, a sound and judicious surgeon, and an assiduous and zealous teacher.

Dr. Tunnen was educated chiefly in Edinburgh, where he served an apprenticeship to Dr. JOHN THOMSON, and was a contemporary of Dr. Gordon, our eminent anatomist. He commenced practice in one of the East-India Company's ships, and was afterwards elected a Fellow of our College of Surgeons, where he became intimately associated with his old preceptor Dr. Thomson, who was at that time professor of surgery to the College. On the resignation of THOMSON, Mr. TURNER Was appointed to the vacant chair. Some time afterwards, when Dr. Thomson succeeded in accomplishing the favourite object of his life, that object to which the whole energies of his intriguing spirit had been directed,-the manufacture for himself of a chair in the University, he contrived also to create a chair of surgery for his eleve TURNER. However much Dr. THOMSON was to be reprobated for the manufacture of those chairs, and the mode in which they were obtained from the Government, no one had any personal objection to offer to TURNER's appointment to one of them, though the object of the creation was palpable enough. The two self elected professors, backed by their political ally at Holland House, succeeded in making their chairs sources of considerable emolument, at the expense of the unfortunate students in the University, for they contrived to get both the topics on which they lectured, addof to the curriculum of " learning" which the pupils were compelled to attend in the mitted to our Edinburgh School.

Dr. Turner died, after only a few days themse, the fille millness, at the 46th year of his age, and scarcely had be taken his lamented depar- no objection, for the same than the same transfer of the confident that I speak the sentiments of more than our friend Pauls.

University

not merely of indiporation, but to secure to them the power of conferring degrees, It seems, moreover, from the nature of the motion of Mr. Tooke, in the House of Commons, on March 26th, 1835, that a royal charter of incorporation had been drawn up and approved of by the law officers of the

Crown in the year 1831.

Now, Sir, what would have been the consequence of giving such a charter to the London University? What but the establishing another monopoly: a monopoly of teachers.

The proof is easy. The object of a college and of all schools is to teach. The skill of the teachers, and the means possessed for To the hatefulness and the injuriousness the manifestation of that skill, ought to be of monopoly, the Government of which you the only grounds upon which any pre-emi-were and are now a member, have testified nence can be claimed. Each teacher beby the measures introduced in various sessions, to destroy, or at least to initigate, tific truths in the most clear and compressions, the evils of some of the most extensive mo- hensive manner. There is a beneficial, a nopolies. So that every imbiasted man scientific rivalry, pregnant with advantage, looking upon these proceedings of the Go-vernment, has come to the conclusion that the necessity is seen, on the part of the Microssequence? To render this apparent, nistry, of abolishing all monopolies, so far take two lecturers, A and B, both of whom as such abolition can be effected with safety, are equally talented. They make known One monopoly that stands must in need that they lecture. They are equal in talent of abolition is exhibited by the Universities to instruct, and in the possession of means of Oxford and Cambridge. These University for instruction. Those anxious to be inties exclude all save those who are of a par- structed hear of their intentions, and deterticular creed, and thus make the honours of mine to place themselves under their inliterature and acience to depend, not upon a structions, some under A and some under man's talent, but upon his religious opinions.

B. But, by some contrivance, B has mathematical maged to obtain a peculiar and exclusive is now very generally felt, and a general cry advantage; namely, that his pupils will be for the abolition of the unsalutary power enabled, by attending his lectures, or teachperpetuating this monopoly, has been raised ings, to obtain a degree, which the pupils of A will not. Does it not follow that plus ad-To that cry it has not been possible, on vantage added to equal talent must give B account of the peculiar constitution of the an injurious superiority? And, in addition, Universities of Oxford and Cambridge, to does it not follow that this superiority must be injurious to A ? And is not the possession What has happened? The evil is felt. of such a superiority a manifestation of the Individuals, not content to wait till the re- exclusive principle, - a monopoly of the worst character?

Such a monopoly would have been estathe House of Commons, and through that blished, had the London University ob-House on the House of Lords, determined tained the charter which they sought. But to realize the privilege of obtaining the they would have obtained a monopoly of a more glaring character, had the charter

a particular creed.

These individuals, instead of going to the ing body. The professors, or the the Legislature, and demanding that an Uni would have become the examiners. The senate would have been the examina own pupils.

. This charter includ

by the Government obviates the harmonic.
And in this view of this important matter mind must agree with Mr. Hame, that " the Government is in the novel position of taking the lead of them" (the proprietors of the University) in the general liberality of the plan."

What then is proposed by the Govern-

ment? It may be stated thus :--

1. That a board of examiners, to be termed the University of London, shall be authorized by charter to confer degrees.

2. That pupils from University and King's Colleges shall be admitted to examination.

3. And that any other bodies for education, whether incorporated or unincorporated, may, from time to time, be named by the Crown, and their pupils be admitted to examination for degrees.

Such are the intentions of Government; intentions indicative evidently of the fact, that degrees are to be conferred upon the prosecutors of every department of learning and of knowledge, divinity excepted.

To this no liberally-minded individual can object. But, in developing the inten-schools. tion, one circumstance occurs which mars degrees are to be conterred are not all who institutions? may be qualified by their learning and knowledge, --- not all who have laboured hard to acquire every necessary information, but this matter with the greatest fairness; but those only who have been educated at "any is it not apparent that the naming the pupils chartered college within the Metropolis."

Now, Su, is not this giving a positive monopoly to the teachers in chartered colleges? Is not this as much as asserting that the education of students is better within the walls of a chartered college than within the walls of any other building? Is not this a spirit of intellectual consecration of bricks and mortar? Is not this a sacrifice to the god of wealth, hecause the largeness of the building seems to Finally. have some weight in the matter? Sir, is it not saying to those beginning their studies in London, " Gentlemen, go to the King's Callege and to the London University (to be called " London University College"); become pupils there, for there you will have talented lecturers: and there, in addition. you will be able to gain honorary degrees?"

But, Sir, it may be said, that the Government plan is not so exclusive as this; for it is expressly stated, in the communication m Downing street to the Council of the den University, dated Aug. 19, 1835, that " Any other bodies for education, whether grated or unincorporated, may, from a be named by the Crown, and admitted to examination

in now proposed clance, that a particular class of pupils is at once admissible to examination for degrees; and this particular class consists of pupils from University and King's Colleges.

Here, Sir, is given at once a priority to those educational bodies over other schools,and why? Are they better teachers at these thus styled "Colleges" than at other schools? Personal comparisons would be invidious, and therefore should be avoided. But it may be asked without fear, Is the education at either of these institutions superior, in reference to the production of real medical qualification for medical practice. to that given at the "private" schools, as they are called?

Let, Sir, an application be made to the examining Boards of the Apothecaries' Company and of the College of Surgeons, and let a report be presented from each body, of the pupils passed or rejected, as belonging to individual schools; and I myself, as an individual private lecturer, am quite willing to abide by the result, as a testification of the nature and of the sufficiency of medical education, as given at the private

Is it then just, Sir, that the pupils of any the beauty of the plan. It is this, that one institution, or of any institutions, should while "the University" can confer all have the priority given them of starting in degrees save those in divinity 'an excellent this intellectual race for intellectual honours, exception,', the individuals on whom these in advance of the pupils belonging to other

I sincerely believe, from various sources, that it is the wish of Government to act in of the London University College and of King's College is giving an undue priority?
It may be asked, "What then do you pro-

pose?"-1 propose, Sir, that the Government of this country, recognising the grand truths, that science has no country, that scientific men have generally been those who have received no aids of collegiate education, should declare, that

Literary and scientific honours shall be onen to every individual, who can prove himself qualified to pomess those honours:

And that, in addition.

Those honours being gained, the individuals gaining them shall have every legal privilege connected with the qualification.

With regard to the latter point, it would evidently be absurd to give an honorary degree as indicative of qualification, and then, afterwards, to require the qualified to pass another ordeal, previous to the realization of the benefits of such qualification.

It is true that such a plan would require the sweeping away, in the present state of society, of many scientific, or rather pseudoscientific, unicances; but the gain would be immense; the loss would be nothing.

And what a noble memento of the Government such a proceeding would be! med, in the preceding What a pleasurable entisfaction would arise

ST MALE STATE

in the mind of yourelf, a member of such a Government, in contemplating the fruits of such a labour! And finally, what a thought to console at the close of an honourable life,-" I have been an instrument in removing a mighty barrier to the diffusion of education and enlightenment amongst the people."

Trusting, Sir, that you are capable of appreciating the high behests connected with the decision of Government on this important question, I have the honour to remain,

your obedient servant.

JOHN EPPS, Lecturer on Materia Medica and Chemistry, and Director of the Royal Jennerian and London Vaccine Institutions.

METROPOLITAN UNIVERSITY DEGREES.

REPLY TO THE LETTER OF "A KING'S COLLEGE STUDYNT."

To the Editor of THE LANCET.

Sir, - I did not expect that the suggestions which I offered in THE LANCET of Dec. 5, respecting the conditions of granting degrees in the New Metropolitan University, would have met with the opposition which "A King's College Student has offered them. I did not expect to be so hastily dignified with the title of "opponent," by a gentleman who is already in possession of those advantages which I merely suggested should be extended to others. But, Sir, as he has appealed to the public to decide which of us is right, I am induced to reply to his remarks, and shall then leave the subject with perfect confidence in your hands, satisfied also in what manner the public will ultimately decide on the question. My opponent takes occasion to reprove me for calamniating a body of men who are "not yet called into political existence." How can I have effected that impossibility? However, the commencement of my letter shows that I did not refer to any set of men, but to consists in the exclusion of all but the ric a proposed system, which I conceived to be from literary or scientific honours, the ne objectionable. But I proceed to his oblections.

Certificates of moral character, he says, are frequently forged. To this I reply, that a written character ought not to be accepted, unless some means are taken to ascertain that it is authentic.

He objects to allowing young men to graduate without having been College Students, because, though it might benefit a few, it would rain the majority, for many who do now attend lectures occasionally, would not then, he says, attend lectures at all. And suppose students did not attend lectures at ali? Suppose they did not study? Why then they would be certain of not obtaining a those, who though risi

In fac degree. think the new system musing ru to any one, it would even students to a sen of the necessity of profession study, and is duce them to seize every opportunity adding to their mental and professional s tainments.

My opponent imagines that I think th students who neglect the lecture-room, a more profitably employed elsewhere study. Those gentlemen who neglect tl lecture-room do so, I should suppose, for f less noble pursuits than those of science. quite admit the benefits of oral instructio I merely argue that if a student does, wit out its aid, obtain as much knowledge one who is in possession of its advantage he ought to be entitled by law to the san honours, and the same standing in society

My opponent next says, that a man car not obtain sufficient knowledge from bool alone, to qualify him to possess a diplom I reply, that a Board of Examiners or fully test this. They can test his knowledg of anatomy and the operations of surgery o the dead body, his knowledge of the pratice of medicine in the wards of an hospita his knowledge of chemistry if need be) the laboratory.

He says, that the duration of the exam nation which would be necessary under th new system, would be so long as to render impracticable in operation. I reply that lengthy examination is not impracticable As it is designed to secure the public again incompetency, the examiners would in doubtedly be fully remunerated for their timand there is no other point than that in que tion. My opponent himself says, that ce. tificates are often forged (and I know the they are often given without being deserved how then can be support a system in which he would allow certificates to play any par

in the conditions of granting diplomas? His last, his most startling, and his only sincere ground of objection, is based on th supposition that the new system would ten to deprive the graduates, as a body, of the respectability. Why, truly, if respectabilit system most certainly would ensure re speciability to the class of graduates; but i as I apprehend, respectability belongs to the mind and not to the pocket, then what is th worth of my opponent's objection? Fe although he may exult at this exclusive sy tem, although he may feel indignant at th thought of a "farmer's or a tradesman aspiring to the honours of learning and skill, yet I can tell him that farmers' an tradesmen's sons deem it as much their righ to aspire to reach the eminences of and will demand (if they should learnt from the corruption. to despise them) equal

in consense. I want a second differen

College " is liberal enough to say the libers no objection to the low-born being raised by their abilities to eminence in a few instances. And why so liberal as regards a few? Because he cannot help himself. Those few have raised themselves already. My opponent and the "exclusive" party, would grant no opportunities to low-born youths to raise themselves. But when, despite all obstacles, despite all prejudices, genius has broken through the castes of society, and raised itself by force of talent to its appropriate station, they then would "not object to a few poor students" occupying stations in the ranks of titled men of science. Whatever exclusions the rich in society may desire to enforce, nature has made no law which peculiarly fits the wealthy for the purposes of literature and science, but rather the contrary. Arrangements of society which set at defiance the laws of nature, are most iniquitous to God and man. In conclusion, let me express a hope that the "King's College Student" will now perceive that he has advocated some erroneous opinions. It is lamentable to hear a gentleman who professes to be a Student of Medicine, with a desire to obtain eminence in the science, supporting the cause of those giddy creatures whom he describes as forsaking the lecture-room for the excitement of dissipation, and doing so at the expense of ardent students who do not chance to be the sons of wealthy men. I am Sir, your very obedient servant,

A STUDENT.

London, December 15th.

METROPOLITAN UNIVERSITY DEGREES.

MONRY AND CERTIFICATE QUALIFICATIONS.

To the Editor of THE LANCET.

Sir,-In differing from the views of "A King's College Student" as expressed at page 420 of a late number of THE LANCET, permit me to make a few observations on the two great questions of subjecting caudidates for medical degrees to a prescribed course of study, and leaving them to follow that which best suits their taste and convenience.

Your correspondent cordially agrees with the proposition, that an unequivocal certificate of good moral conduct should be reed; yet according to his arguments for the present system as a means of sustaining the "respectability" of the profession, he ect this object not by a written morality, but by a plan which, the aspirant an opportunity

ment of King's clear not only opens to a girdy youth an enhim with those "oblivious antidotes," the false certificates, by which he obtains admission to an examination, at a time when, probably, having exhausted his pecuniary resources, exigency compels him to stand the test. To the dread of this test, insdequate as it is, will such an one owe the little knowledge he may be found to possess, and not to any obligation imposed and inevitably exacted by the certificate system. How often does it happen that the candidate, after having squandered away his time, and deluded his friends by the display of certifi-cates of "diligent" attendance on lectures, &c., has recourse to a "grinding," by which he is "crammed" in a few weeks with what is supposed to have taken him some years in acquiring!

Your correspondent's assumption that an expensive education is likely to be obtained only by persons of good birth, is erroneous indeed. Were the degrees given to a student to be measured by the length of his purse, the sons of "farmers" and "tradesmen would carry much more respect than your correspondent seems to allow them. I recollect the landlady of a small country inn, who was bringing up her son as a "doctor," boasting that he would "come out as big a gentleman as any in the land," because, forsooth, she was plentifully supplying him with that which in her estimation could not fail to effect the object. This feeling, vulgar as it is, will have at least the appearance of truth on its side, so long as illiterate young men can find their way into the profession upon a money qualification.

As my object has simply been to show the fallacy of an hypothesis upon which is based many of the arguments in support of the certificate system (which, from observation, appears to me to work very ill), I here conclude. What alterations are most likely to answer, it is not for me to suggest. This is now, happily, the province of an enlightened body of individuals, to whose judgment, nided by THE LANCET, and the experienced voice of its Editor in the senate, the public may confidently commit the cause he has long so ably advocated. I remain, Sir, yours truly,

A LONDON UNIVERSITY STUDENT OF MEDICINE AND SURGERY. December 17th, 1835.

ST. GEORGE'S HOSPITAL.

DISTARE OF THE BONES OF THE ILIUM.

WILLIAM HARDEN was admitted, Sept. 16th, into Winchester ward, when, Sir Bun-JAMIN BRODIE being out of town, Mr. CUTLER took charge of the case, who at socketful of money it is once told the patient that his was not a

F. 1885

fit case for the hospital, and then added that | boy was then! he must take rest and apply poultices, these remedies being of great efficacy in such with two large sinuses (one leading from the trochanter major, the other from the secrum), extending to dead bone. Leeches were afterwards applied, and house-physic was given, and on the 25th of September, Sir BENJAMIN first saw the man. We then learnt that about eight years ago he first felt pain in the affected hip, for which a surgeon to whom he applied, also recommended rest, at the same time opening two large abscesses (which have now degenerated into sinuses) and letting out a large quantity of matter. The pain has continued wards, and the fore-arm being half flexed, more or less ever since. The hip-joint is the bones were drawn away from the joint nearly anchylosed, but the patient complains of no particular fixed pain in any part of the limb. The thigh of the same side is enlarged, but there is no perceptible difference in the length of the two limbs. He was ordered half a pint of the compound decoction of sarsaparilla, with two drachms of the extract of sarsaparilla daily, and the boy left the hospital with his father. one-eighth of the oxymuriate of mercury in a pill. This plan of treatment (according effect on the constitution.

Oct. 9. The patient has steadily persevered in the use of the remedies until this ever. The physical force of arms, legs, and day, when the oxymuriate of increury have towels, was therefore employed. Mr. KEATE ing deranged his bowels, it was discontinued and Mr. Basington were antagonists to pro fempore, and he was ordered the Infu- Mr. HAWKINS, but their strength was soon sion of Casparia with Tincture of Kino, twice exhausted. A poultice was ordered to be applied, and the sarvaparilla medicines to be continued. The man's countenance is pallid, unhealthy, and auxious.

DISLOCATION OF THE RADICS .- A little boy was admitted with this injury about four months since under the care of Mr. Keate. The accident occurred from his being thrown from a pony. He was brought to the hospital about a fortnight after the accident the tumours of the finger had supervened, had occurred, and Mr. KEATE first tried to reduce the dislocation over his knee, but failed. Several other attempts were made, by manipulation, and extension with towels, at various times, but all of them failed; and but was not obtained. after the boy had been in the hospital upwards of a month, a consultation was held as to the propriety of making further at-tempts, and decided in the affirmative. The mission-rees, Sept. 10

for the care of Nir B. for the care of par partition of the countenance was extremely idjette, and had countened that countened the appearance of his baving just a from an epileptic fit. The only account then obtainable was, that he had been shot in the head, and he was observed to have a drawing back of the head. In consequence of his distressed appearance he was immediately sent to one of the upper wards to On making some further inquiries into the history of the case, it appeared that about a month since he had been shot in the back of the head over the occipital region, and that some of the shot had been extracted by a medical gentleman who attended him. He has now but little power over his lower limbs; the senses of sight and hearing are very much impaired, and he complains of great pain over the whole re-gion of the head. He was immediately ordered calonel and opium.

Sept. 23. Sir B. Brodie saw him to-day, and ordered the medicines to be continued; a blister to be applied over the back of the neck, and kept open by the green savine ectate.

25. He is quite amaurotic, and his sense of hearing is still very imperfect. The drawing back (opisthotonos of the head, which was very great when he was admitted, today is so newhat less; the blister has discharged freely, but by some mistake it has been dressed with savine and mercurial ointment mixed, and this double mercurialization of the system by blister externally, and the calomel internally, has affected the mouth, and his gums are red and spongy. The head was ordered to be shaved, and the present blister to be dressed and healed, and another put on higher up over the occiput, and kept discharging with savine corate only. The calomel and opium, which had been given three times a day, were ordered to be given only once daily.

Sir Benjamin Brodie remarked that this case was a very interesting one, and requested his clinical clerk to keep an account of it. In all those cases of injury to the brain, in which opisthotonos had been remarked, in which he had witnessed the post-mortem examination, there had been found a collection of pus about the tubercuhum annulare and medulla oblongata. "I have seldom (he continued) observed loss of vision in these cases, but as it is now said that the optic nerves can be traced as far back as the corpora quadrigemina (the testes), and as these parts are all situated near one another, it is but fair, I think, to mude that there is some deposition of pus seese. I remember one case of injury and in which there was loss of sight, death, there was found a transof the bones at the base of the contic nerves were disthe sphenoid bone.

idiote, and had displayed by account then been shot in read to have a in consequence is weet things sweet, and yet the patients have respectively as a few that the patient. I have known the patient to be in consequence in consequence is weet things would taste sour, and bitter the was immentally as the patients have respectively.

Oct. 2. The same treatment is persevered in, and with very good results. The deafness is less and the amaurosis diminishing.

The opisthotonos is nearly gone.

Oct. 10. Since our last report he has had rather a severe epileptic fit, the peculiar phenomena of which it buffled the nurse's skill to describe. He was bled, and took calomel and Eprom salts to affect the howels, which have been very sluggish. The "head" symptoms remain much the same, without any progressive amendment.

same, without any progressive amendment.

20. He has had frequent returns of epilepsy, for the relief of which Sir Benjamin ordered him to be put on full diet for a few days, but without, as may be supposed, producing any sort of influence on the attacks. His other symptoms are much the same,—certainly not better. The sphincters ani and vesice are relaxed; as the nurse says, "the does everything under him." Sir Benjamin thinks that the disease is beyond the reach of medicine, and looks to the pathology of the case with interest.

THE refusal of Mr. LISTON to accept the Chair of Surgery in the University of Ediaburgh, does not appear to have been by any means satisfactory to the feelings of some of the magnates in modern Athens. In reply to an article which appeared in the Scotchman of last week, the London Courier evening paper, of Dec. 19, wrote as follows:—

"The notice which our worthy conternporary the Scotsman has taken of an article in last Saturday's Courier, relative to the recent appointment of Sir Charles Bell to the Chair of Surgery in the University of Edinburgh, as well as the remarks made upon that article in the Town Council of Edinburgh by one of the members, render it indispensably necessary for us to reassert the accuracy, to the very letter, of that part of the article in the Courier, in which it is stated that " as soon as it was ascertained, by reference to Mr. Liston, who has lately settled in the metropolis, that he would not forego his prospects in London for any of the medical chairs in the University of Edinburgh," the members of the Edinburgh Council resolved to elect Sir C. Bell.

"Mr. Liston, we have reason to believe, received the first intimation of its being the

wish of certain members of the Council to alluded, will bestow the vacant Chair on him, when he was recently in Edinburgh, to which he had been called soon after the death of Professor Tunner, to perform an operation of no trifling description. The truth of our assertion, however, does not depend on verbal conversations, but on the unerring testimony of written documents, which passed between members of Council and Mr. LISTON, and which have been in our hands.

"Sir CHARLES BELL's friends scem to us to have acted injudiciously, and to have shown more sensitiveness than discretion in originating this discussion. Whatever may be the respective merits of Sir CHARLES Ball and Mr. Liston, we certainly never meant to institute, in the columns of the Courier, any comparison between these eminent professional men, either as public teachers or as skilful and able surgeons. We merely stated facts known to us, and whatever might have been our private opinion as to the result of the election, had Mr. LISTON as well as Sir C. BELL been in the field, we neither assumed nor insimuated Hapital, expecting the selected to the chair, had be been willing out permission. We cannot politish it with been elected to the chair, had be been willing out permission to append the name of the writer. The answert to obtain populs at new establishments, I had to accept it. His decided refusal made the election of Sir CHARLES BELL " the fittest admissions at the outset of their career. individual, who was willing to accept the

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE VI.

ANEMIA OF THE BRAIN AND CEREBRAI REMORRHAGE.

GENTLEMEN,-We have now traced the complication. history of two of the great divisions under which we arrange diseases of the central part of the nervous system, viz., congestion and inflammation. We shall now, there-litself, or coincide with a similar state of forc, pass to a consideration of the accidents aucinia in the rest of the body. Thus we connected with anemia, and then terminate have frequently occasion to observe it after this part of our subject with cerebral he- the occurrence of considerable hemorrhages; morrhage, or apoplexy.

which is especially remarkable in this point cause is often seen in children affected with of view, that it often gives rise to pheno- acute gastro-enterite, at the termination of mena which very closely resemble hypere- which we observe symptoms that seem to mia, and yet it is evidently a matter of the announce a state of irritation in the brain, utmost importance to distinguish these two while, on the contrary, the organ is anemic, opposite states from one another. In prac- and presents, after death, an extreme degree tice, you will frequently have to ask yourselves this question, " Do the functional derangements of the nervous system which present themselves, depend on too great an general quantity of the blood, or a deterioafflux of blood to the brain, or are they ration of its quality. Here the disease is connected with a condition quite opposite, confined to the brain alone, and depends on viz, anemia?" It is unnecessary to say, that hypercuia and anemia will require tion in that organ. Afterent modes of treatment; let us, therecase; and first, for the

LCharacters of Cerebral Anomia.

stance of the brain. The gray substance is much more pale than in the normal state: it contains a less number of vessels, and thus approaches in its general appearance to the white or medullary portion of the brain. In some cases the organ looks as if it had been macerated in water for a considerable time: and BILLIAND relates that he has sometimes found the cortical substance of the hemispheres so completely decoloured and pale. that the surface of the brain resembled a mass of modelled wax. The state of the nervous centre just described, may exist alone, or become complicated with other changes of structure. In some cases it has been observed to coincide with a peculiar hardening of the cerebral mass; in others the brain is softened, and does not present its usual consistence; however, we now propose to examine anemia in its simple form, when it exists alone, and without any

Its Symptoms.

Anemia may be confined to the brain or it may be a consequence of chronic or Anemia of the nervous centres is a disease acute disease. The influence of the latter of paleness. Sometimes, however, anemia of the brain may occur without any disorders which indicate a diminution in the causes peculiarly influencing the circula-

Anomia gives rise to the existence of cerlitter into a few considerations on this tain symptoms, whose connection with it as a cause we can prove upon living animals. If we bleed an animal to such an extent as suddenly to deprive him of a large portion mervous centre is charac- of blood, we give rise to a series of sympwould lead you to sup-toms that, under other circumstances, we of the sub- might easily attribute to excitement of the nervous system, and the animal is seized and wholeson with general convulsions, and these become more and more intense in proportion as the brain becomes empty. In the human subject we observe the same phenomena. After traumatic hemorrhage, copious loss of blood in uterine hemorrhages, &c., the patients are frequently attacked with nervous delirium, convulsions, and other symptoms, which we have pointed out when treating of conges-Hence we establish this general rule, most important in practical application, that a diminution of the normal quantity of the blood gives rise to the same symptoms as hyperemy, or an increased quantity. Look at the digestive organs: a difficulty of digestion coincides equally with an increased injection of the mucous membrane of the stomach, and with an abnormal paleness of this same membrane. In the latter case, as in the former, digestion is troubled, because fashion, the intellectual faculties of the prithe organ no longer receives the quantity of | soner commenced to show some symptoms blood necessary for the normal accomplish- of trouble; his strength and flesh declined ment of its function. In the lungs, dysp-at the same time; finally, he was seized not sequally produced, either by an hyper-emia more or less considerable of the pul-came afterwards more and more furious; monary tissue, or by the fact that the the patient cried out from time to time in find enough of blood to vivify. In the was constantly surrounded with horrible centre of the circulating system we may figures. The physician called to attend him observe a similar phenomenon; thus the in this dangerous state, having informed of blood, and in the opposite condition, consisted in the abstinence from spiritu-when its cavities are imperfectly filled by a ous liquids which he was compelled to obpoor and impoverished fluid.

These examples we might multiply infinitely. The nervous centres furnish us effect of this change of regimen was soon with a great number. We may therefore, I say, lay it down as an established principle, that the brain, like the other great apparatuses, presents specific symptoms when it ceases to be stimulated by the normal quantity of blood. Let us briefly chumerate these symptoms. They are, 1st, Those connected with the intelligence. Delirium is a common symptom of cerebral anemia. Dr. PAPAVOINE, an ex-interne of the Hopital des Enfans Malades, has published several cases of children affected with the most violent delirium, and dying in this state. After death no other lesion could be discovered in the brain, except a complete decoloration of the gray substance which appeared confounded with the white. We observe the same delirium in persons accidentally submitted to a forced abstinence, or in patients weakened by a former malady, and kept on too severe or prolonged a diet. In these cases we observe functional disorders, resembling closely those depending upon congestion, but certainly in no way connected with that state, for they gradually disappear as the blood is regenerated, and under the influence of a generous

A remarkable case of this kind has been published by a German physician, Dr. HANSBRANDT. It illustrates perfectly the point we have just advanced: - A man, given excessively to drinking, was thrown into prison for theft, and of course reduced at once to the prison diet, bread and water. After a week or two living in this new air, in penetrating the vesicles, does not the most agonized manner, and thought be beart is equally affected with palpitations himself of his previous habits, suspected that when it is distended with an over-quantity; the cause of his mania and other symptoms serve; he therefore ordered a small quantity of brandy to be given twice a day; the obvious; the cerebral accidents gradually disappeared, and the patient recovered his flesh and strength, and continued to enjoy perfect health during the remaining period of his detention.*

The faculty of movement is also more or less disturbed, in consequence of cerebral anemia; thus, we have already noticed the convulsions which supervene after copious hemorrhage, or in animals from whom a large quantity of blood has been designedly abstracted. The sensibility is sometimes modified in a remarkable manner; the least stimulant produces effects infinitely more rapid and energetic than we observe in the normal state of the economy. In several cases of anemia, it is not rare to see a marked exaltation of sensation. If we place a blister on the skin, the sensibility is awakened at once, acute pain is produced in the part, and the whole system partakes of the excitement. This is a point to which you should pay attention in practice. your patient's strength has been on ably reduced by sanguineous em particularly cautious and re employment of cutaneou

Examples of this kind are chiefficen in children, or an individuals endowed with what is called a seon in children, or .a. nervous temperament. You have already seen how hyperemia and inflammation of the brain are often produced by increased stimulation of that organ. We may produce the same effects, or, rather, give rise to the development of exactly similar functional disorders, by withdrawing the quantity of any stimulant to which the brain has been accustomed.

[·] Journal Hebdom. de Médecine, Dec. 1825.

ningle blister, a: produce a degree or socal distr general excitement which you great difficulty in mastering.

Treatment of Anemia.

We have now laid before you the prominent characters of anemia as connected with the central organ of the nervous system. It remains to say a few words on the treatment of this disease. The analogy between the symptoms of hyperemia and anemia has been frequently alluded to. Your first care must, therefore, be to distinguish between them. Having once satisfied yourselves that the nervous symptoms under which the patient labours, depend not upon congestion of the brain, but on anemia, the indication is a very simple one. You must employ every means in your power, by which the normal quantity and quality of the blood may be restored; in a word, you must make new blood. Be careful above all things not to attribute the phenomena of cerebral anemia to any other cause, or you may commit the most fatal errors in practice. Thus, for example, when a patient in the last stage of typhus fever, after twenty or thirty days' suffering, after strict abstinence &c., is seized with delirium and other cerebral symptoms, are we at once to conclude that he has congestion or inflammation of the brain? Certainly not. Support your patient under these circumstances with moderate cordials, light nourishments, &c, and you cure. Bleed him, and you hasten effusions of blood. Again, the hemorrhage the fatal termination.

CEREBRAL MEMORRHAGE.

We have now studied several morbid conditions of the brain; we have next to take up a subject to which more interest is attached than perhaps to any of the questions that have hitherto occupied our attention; we have to investigate the nature, symptoms, and treatment, of cerebral hemorrhage. This disease, as you know, has been long known under the name of apoplery, a term employed to indicate a sudden loss of motion, sensibility, and intellect, supposed to depend upon effusion of blood into the brain, but I think that

We cannot preserve the word " Apoplexy" any longer in the Science.

It is too vague; it does not indicate with precision the material change in the organ. hut, like all other similar terms capable of various interpretations, it lends itself to every theory, and in the end serves no real ose but that of covering our ignorance. in give rise to the same symptoms Eviz., sudden loss of conscious-See how the effects of sim-legamolisms ment, &c., are

be enough to On the other hand, hemorrhage into the substance of the brain (the essential anatomical character, remark, of apoplexy) may take place without producing the ensemble of symptoms compressed under the word apoplexy. Thus we may have hemorrhage of the brain without loss of intellect. may observe loss of intellect, and derangement of sensibility, while motion remains intact. You will see this presently. We therefore, I say, must reject the term apoplexy from medical nomenclature, because it refers to various forms of injury in the brain. We reject it, because it represents. identical symptoms depending upon various and quite different causes.

Situations of Cerebral Hemorrhage.

Hemorrhage of the centre of the nervous system may occur at any point of the cerebro-spinal axis. However, it has been observed more frequently in the substance of the hemispheres than in any other part. Again, there are certain portions of the hemispheres which seem much more subject to this accident than others. from an examination of a large number of cases of cerebral hemorrhage, we find a great majority to take place in the nervous pulp, on a level with, and outside of, the corpora striata and optic thalami. One or other of these latter parts may be attacked in an isolated manner, or both together; but it would appear that the striated bodies are much more subject than the thalami to may exist beyond the points we have just mentioned, or in the mass of nervous matter called centrum ovale. Finally, in some cases the effusion of blood does not take place in the interior of the brain, but at its surface. The blood is shed between or on the convolutions, and then represents an uniform layer, spread over an entire hemisphere; or it may be confined to a single

There are, again, other parts of the cerebro-spinal axis in which effusion of blood may take place, but much less frequently than in those we have now spoken of. Thus, hemorrhage occurs in the substance of the pous varolii, or in the prolongations which it sends off to the cerebrum or cerebellum: or, finally, in the substance of the latter organ itself. Apoplexy of the cerebellum is, however, a very rare disease, and hore. as in the cerebrum, the effusion may have its scat in the median lobe, or in one of the lateral hemispheres. The medulla oblongata also presents us with examples of hemorrhage, and the spinal column in any one point of its extent.

The central parts of the brain, properly so called, are much less frequently the seat of hemorrhage. Thus it has been cheeved but seldom in the inferior part of the cen-trum ovale, and in the septum lucidum in

Authors sometimes speak of whitish, another species of hemorrhage, viz. that 's which takes place in the interior of the ventricles; but these also are rare. We certainly find blood effored into the cavity of the ventricles in many cases of anoplexy; but if you examine with care, you will find the blood has made its way from the nervous pulp surrounding them; or, for example, when the septum lucidum is broken down, the blood may traverse that space, and pass into the other ventricle; both cavities will then appear full of blood, but there is almost always a communication between them and the accidental cavity formed by the effusion of that fluid into the substance of the brain. The hemorrhage may take place in the tissue of the pia mater, which envelops the cerebral convolutions. This form of effusion has been called by M. SERRES " meningeal apoplexy;" it is a very rere variety, and when we have occasion to This is a question of some interest in the observe it, we generally find at the same history of apoplexy. It may remain untime an effusion of blood in the brain. The changed until the death of the putient, or, fluid finds its way into the membrane from under other circumstances, it may gradually the apoplectic cell, in the same manner as diminish, and eventually become absorbed, it does into the ventricles. Sanguineous In this latter case nature performs an exeffusions into the centre of the nervous system readministry and beautiful operation, which tem differ considerably in extent in different commences with the removal of the effused cases. Sometimes the cell is excessively blood, and terminates in the cure of the pasmall: so insignificant that it would scarcely ticut. We have already noticed the changes contain a pin's head. In other cases the that take place in t'e blood contained in an bemorthage has been abundant the cell is apoptectic cavity. At first dark and fluid, it wast, and occupies nearly the whole of the gradually loves its colour and consistence, hemisphere. The number of these apoptection the aboutting of the more fluid parts. sic cavities is as various as their extent; we At hogth we find that nature has prepared may find but a single ove; sometimes two an apparatus for its note complete temoral. or more. In some cases, on the contrary. The coagnium is new contained to a round the brain appears, as it were, riddled with or uregular cavity, whose parietes are lined an immerse number of these hemorrhagic by condensed cellular membrane, forming a cavities, which have been formed either at yellowish cyst, very analogous to a serous the same time or successively, one after the cyst. This cyst secretes a kind of secons other. Certain effusions of blood exist free fluid, whose use appears to be to penetrate quently alone; for example, those seated in the coagulum, separate the different parts the different parts of the hemispheren; but of the blood, and render it more easily ab-others, on the contrary, do not occur unless, sorbed. Still later, upon examining the we have effusion somewhere else. Thus in by cyst, we find nothing but serum or a gelafar the greater number of cases where blood tinous fluid in its cavity. The parietes are has been found effused into the substance of connected together by a number of fibrous the cerebellum, an hemorrhage has at the bridles that pass from one side to another, same time been discovered in some one and intercross in various directions. The part of the cerebrum; and this is perhaps effused blood is now completely absorbed, one of the principal reasons why apoplexy of but nature does not rest here; she now the former organ is so little known, why we commences the task of removing the evet : are so imperfectly acquainted with the his- and the latter having enjoyed for a certain tory and symptoms of hemorrhage of the time its provisional existence, is gradually cerebellum.

The Appearance of the Effused Blood

varies much, according as we have occasion to examine it at a period more or less removed from the instant of its effusion. In recent cases, the blood is generally of a blackish colour and liquid consistence; at a nected manner, by Messra. Re-later period, it resembles currant jelly, sur-rounded by some blood still quite fluid. Still cicatrisation in the later it becomes more solid, yellowish, or the process allow

loges entirely its lour and up barance. If we neek

the part from which the hemorrhage takes place, we find two different sources. let. In some cases it is effused from the capillary vessels, and on examination we are unable to determine the exact point whence it has proceeded. 2nd. A vessel of some magnitude may bave been ruptured, and given rise to the effusion. In this latter case, we can frequently discover the injured vessel on the surface of the apoplectic cavity, but it is right to warn you that in some other cases the ruptured artery has been found very far from the neighbourhood of the effusion, with which it is connected by a pedicle that might easily escape notice.

The Blood once Extravasated from its Vessels, what becomes of it!

This is a question of some interest in the effaced, until no trace remains of the original accident, except a simple linear cicatrix, or a cicatrix with puckering and depression of the cerebral substance.

It was only within the last few years the series of transformations we has briefly described were followed as

4

A modern author uished two ways in which th be affected with regard to the st stance. He has longht to er 166 cought to establish two forms of cerebral bemorrhage. In one there is laceration of the brain, with a greater or less loss of substance. In the other, the cerebral pulp is not injured; the blood is simply effused between two layers of the cerebral fibres. In the first case, accompanied by laceration, where the nervous substance is completely broken down, we may ask ourselves if the nervous pulp can be so far reproduced as to transmit volition &c through the injured part. Dr. FOVILLE thinks not. But the possibility of such a regeneration seems established by the experiments of M. SERRES. Besides, do we not know that a divided nerve may unite, and continue to transmit nervous influence as before the injury took place?

Period when Cicatrization is completed.

We cannot lay down any fixed rules upon this point: the time varies considerably in different cases; sometimes the process of cure is very rapid, at other times it is tediously prolonged. In some cases, after a lapse of five or six months from the first appearance of cerebral symptoms, we find that the coagulum has been removed, and nothing remains but a trace of cicatrix : in other cases, on the contrary, the serous cyst of which we have spoken has been found many years after the occurrence of the original accident.

We have hitherto been occupied with the contents of the apoplectic cell, and the man-

State of the Brain in the immediate vicinity of the Effused Bload.

The vessels may present nothing particular, or have undergone an important modification which it is necessary to mention. In several cases of cerebral Lemorrhage we find the vessels assified in a high degree, or so friable, that the least effort is sufficient to rupture their parietes; and you know that in aged persons, who are peculiarly subject to sanguincous effusion of the brain, this state of the vessels is very common. vessel may give way on the wall of the anoplectic cell, or at a certain distance from it, and in that case the hemorrhage may result from the rupture of a great vessel on the surface, or at the base, of the brain. M. Seants has seen a case produced by the rupture of the basilar actory, not far from its bifurcation: the blood here made its way into the ventricles. The nervous pulp itself present certain alterations in or around eplectic cell. It may be absent, or we is broken down, lacorated, and other truce of organization of vascular tissus. Now

has distin- | rhage of the brain? I am inclined to think that in a great many cases the effusion of blood is preceded by a certain degree of softening of the nervous pulp. The proof is this,-in many cases we can follow, in the softened portion of the brain, all the degrees by which a simple injection of blood is transformed into a more or less extensive effusion : we see the latter commence by a number of small red points, which gradually unite, multiply, and enlarge, to form, in some other portion of the softened mass, a true apoplectic coagulum. llowever, we should distinguish this species of ramollissement from others of a decidedly inflammatory origin.

Let us now examine the state of the nervous tissue around the seat of the hemorchage. In some cases the cerebral substance immediately around the cell may be in its normal state, but this is rare; in others the pulp is more or less coloured and injected, and bears marks of having been the seat of irritation : in other cases, again, the coloration of the nervous pulp seems to depend entirely on imbibition of the blood: the parts surrounding the coagulum are the seat of a true ecchymosis; hence it may present a great variety of colours, bright red, red, pale, yellow, Ac., according to the vicinity of the cell, in a word, the cerebral substance may present all the shades of coloration which we observe in ecchymosis of other parts of the body.

The nervous tissue surrounding the effusion may be in a state of true ramollissement. This change, as M. LALLEMAND has ner of its removal. Let us now examine the demonstrated, may take place before the effusion, or it may succeed it, and then give rise to quite another order of symptoms. When the effusion is recent, the nervous substance around it may present several modifications : it may, as we have just remarked, be more or less softened; it may be infiltrated with purulent matter: finally, in some cases, we find a very considerable induration, which many authors attribute to chronic inflammation, in the immediate vicinity of the apoplectic cell.

Let us now leave the environs of the ef-The fusion, and consider the

State of the Cerebral Mass in general.

We frequently find in the brain, marks of very considerable congestion, and this is a circumstance of importance to observe, for many of the subsequent symptoms depend more upon the degree of hyperemia which thus occupies the nervous centre, than on the actual hemorrhage itself. As the work of cicatrization goes on after the absorption of the congulum, this congestion may be repeated at uncertain intervals, and it requires the utmost care and watchfulness on the part of the physician. When very considerable hemorrhage has taken place into to the hamor the substance of the brain, the opposite

hemisphere to that affected may also become | quest towards compressed, and that in two different ways. 1st, By the congestion of one hemisphere, giving rise to an increased bulk, and acting directly upon the other, which it compresses. 2nd. By the passage of blood through the lacerated central parts, from one hemisphere to the other. These circumstances have an influence on the appreciation of the signs of cerebral hemorrhage, and are therefore not to be neglected.

Now let us inquire in what state do we find the membranes? They may remain altogether intact, or be infiltrated in a great-

er or less degree with blood, scrum, &c., and thus become a source of complication of the times than at a period not so very far resymptoms. When the hemorrhage is of moved from the present. We have now to long standing, the membranes may exhibit other lesions connected with the duration of the primary affection. Thus the pia mater covering the convexity of the brain, may be very considerable quantity of serum in the to add to what his been already said in the ventricles; this latter is a case which we sometimes meet with in practice. A patient join, by way of supplement, that the abuse been been already and in the practice of the property has been attacked, perhaps several years of spirituous liquous, and the frequent ad ago, with apoplexy: the first symptoms pass off, but a new set is slowly developed of cerebral hemorrhage, as well as of contact the contact of the You now recognise chronic hydrocephalus, gestion. Another quastion is the following. The patient dies, and on the autopse you. What influence do the different states of the find together with the find, together with the traces of an ancient, hervons centres exercise to the production effusion of blood, a considerable quantity of of cerebral homorphage? They consider the act of according take place in the venous circulation, we have nothing new to add to what has been exciting causes of apoplexy; but the cases air cady said on congestion. The causes of the one act equally in the production of the rare, very rare; if there existed any real other, though perhaps with a less degree of connection between apoplexy and labour,

Is the Influence of the Sex fell in the Doog-Imponent of Cerebral Hemorrhage?

Are males more subject to this disease than females, and if so, in what proportion? at giving rise to any symptoms Josuan FRANK used to say, " inter decemapoplecticus unam numerare soleo femiinflu-influ-influ-gerated; apoplexy a a disease more fre-distry quently seen in females than you may be

led to expect from the aphorism of FRANK; | finally, M. habit of attending at Salpetriere must be died to be already aware of this low Party and the died to be already aware of this low Party aware of the low Party a published a statistical account of 1241 cases of apoplexy observed at Vienna, in which the sex of each individual was noted. Of these 1241 cases, 637 occurred in persons of the male sex; the remaining 604 were females. Here, you see, is a great difference, from the result of JOSEPH FRANK's observations. A French physician, M. FABRET, has made a similar calculation on a larger scale: he has collected 2297 cases of cerebral hemorrhage, and found that 627 of the individuals so attacked were women. This proportion, again, differs sensibly from that of PETER JOHN PRANK, but is far from approaching the relation of one in ten, laid down by Joseph FRANK. The next point we have to examine is, the

Influence of Aye

in the production of cerebral hemorrhage. Are spoplexies more frequent at an advanced period of life than at any other? Certainly so; the result of investigations made by M. ROCHOUX, and others, bave placed this beyond any doubt, and show that after the age of 50 these hemorrhages become common, and acquire their maximum of frequency in a period between that and 70 years of age. In childhood and up to the period of 35, they are rarely observed. These results are perfectly in secondance with the aphorism of Hiero-CRATES, which indicates the greater frequency of cerebral hemorrhage at an advanced period of life. particular, has occupied himself in the solution of this question. He has made a relevé of 61 cases, and found them distributed in the following order, viz. from 30 to 40 years of age, 10; from 40 to 50. 7; from 50 to 60, 13; from 60 to 70, 24; from 70 to 80, 12; finally, between the age of 80 and 90, he observed only a single case. The cerebral hemorrhage seems to diminish; and, gradually recover. finally, that it is equally rare before the age of 39 or 35 years. The rare occurrence of Queen's Ward; and in this instance I have cerebral hemorrhage at the two extremities not so favourable a report to make. She of life seems thus established; however, we was twenty-six years of age, a housemaid, are not without examples of apoplexy at a and the mischief had arisen in consequence very early period of existence. I myself of a severe blow from a fall. Although the saw a young boy, thirteen years of age, who report states that the secretions have b died rapidly under the symptoms of effusion died rapidly under the symptoms of effusion pretty regular, yet there has been a of blood in the brain; after death 1 found thing wrong constitutionally, which has an encemous congulum in one of the hemi- fluenced the local complaint. heres. meeting.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

UN CARES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE II .- DISEASES OF THE KNEE-

Termination of former Cases of Disease of the Hip-Joint. - At our last meeting, gentle-men, I detailed to you the history of four cases of disease affecting the fibrous capsule of the hip-joint, giving the progress of each case up to the date of the lecture, all of them, with the exception of one care, at that period being in the house. The third patient, a boy, had been presented cured at the time I delivered my remarks, and since then two of the other patients have likewise left the hospital. The patient in the M. Rocnovx, in second case, Septimus Carter, in whom the local disease was complicated with tebrile symptoms, though not yet perfectly well, left the hospital by his own desire, that he might have the benefit of a better atmosphere than he could obtain here, as he resides at a short distance from town. He has now but very slight pain, either of the knee, or of the hip upon pressure in the groin; he can move conclusions at which he arrives from the about with tolerable freedom; in fact, his above numbers is, that the maximum of sufferings are baidly to be considered of any cases of apoplexy occurs in the fifteen years importance, and I am sure that he rest, and which are comprised between 55 and 70; improvement of his general health, if he be that after this latter period the tendency to not guilty of some imprudent act, he will

The fourth case was that of a woman in

will the look affection grade. To diff she com the hip upon pressure being sende anterior part; but when pressure anterior part; but when pressure is applied over the posterior part, she feels a kind of soreness merely. The pain of the knee is not constant; it occurs at night, and noon pressure on the anterior parts. The uterine functions are regular. She has not a good appetite, though the secretions are good and regular. I have given her, in consequence of there being a diminution of the general powers, the mistura potassic hydriodatis. We have applied a fresh moza to the joint. and I trust at our next meeting I shall be able to give you a more gratifying report. However, so far as all these cases go, they show well the nature of disease of the fibrous capsule, and that the plan of treatment which has been resorted to is likely to be efficacious in the majority of such cases, three of the four cases having been cured, and the remaining case being nearly so.

I shall this morning direct your attention more particularly to cases of disease of the knee. I should have liked to pursue the subject of disease of the bip farther, bad I had cases in the house to illustrate how discase affecting that joint attacks the synovial membrane, the cansule, and the cartilages, proceeding to abscess, destruction of the cartilages, and, occasionally, to disloration; but having no such cases, and desiring to keep these clinical remarks as closely connected as possible with cases nader our guidance at the time they are delivered. I shall proceed to speak to you of diseases of the knee.

Case 1 .- Inflammation of the Synocial Membrane of the Kner joint, with Increase of its Secretion .-- The first case I shall advert to is one of inflammation of the synorial membrane of the knee-joint, with an increase of secretion from inner surface of that membrane. It has occurred in Thomas Clarke, a carpenter, aged 23, of temperate habits, residing at Kennington. He was ad he stated that about twelve months ago, being in the habit of kneeling very much in his business, having been planing boards for

retro-| between the inner condyle and the patella, and the patella; also upon pressure be-tween the ligamentum patelle and the ex-ternal lateral ligament. The synovial capsuff was distended, and puffed up with fluid, more particularly apparent in the parts I have described, and at each side of the tendon of the rectus. The general health was tolerably good. He was directed at that time to keep his bed, that the limb might be quiet, and a blister wat applied to the surface.

On the 27th it says the pain is now of a sharp darting character, occurring at intervals only; and that it may be produced by pressure over, or by motion of, the joint. The swelling is much less. The blister healed under the application of a simple poultice, and another blister was directed to be applied.

31. Pain less, and he can move the joint without increasing the pain.

Nov. 4. Scarcely complains of any pain; swelling nearly gone; rests well at night; appetite good, and secretions regular.

11. No pain on pressure, or motion of the joint; swelling subsided; general health good; secretion regular; presented cured.

Anatomical Structure of the Knee-joint .-

Ax all my remarks to-day will refer to mischief to the knee articulation, perhaps I may be excused in the outset in offerior a few brief remarks on the anatomical structure of that part, as our diagnosis must depend a good deal upon examinations conducted on anatomical principles.

This articulation, then, admits of motion in two directions only,-flexion and extension, as they are commonly called; and, cousequently, this joint is placed among the guighymoid, or hinge-joints. The joint is formed principally between the lower part of the femue, and the upper part of the tibia, with an interposition of fibro-cartilaginous bodies, which aid in forming the joint, and are termed the semilunar carti-lages, from their figure. The motions of mitted into No. 8, Abraham's Ward, on the the joint are restricted principally by bands 22nd of October last. Upon his admission of fibres termed ligaments—a very strong one on the inner, and two on the outer part; and these are termed the internal and external lateral ligaments. We have, further. floors, he observed a slight swelling of the a portion of the tendon of the large rectus right knee, unattended by pain, except on muscle proceeding from the thigh over the exposure to cold. The swelling gradually patella, improperly called the ligamentum reproduce to the state of the particularly so upon patches, which should be regarded, however, taking much exercise. He had genormos as a continuation of the tendon of the recabout two years and a half ago, but the distinct the patches, the placed more distant from the patches, the state of the present the patches of the present to notice, a quantity of fasty matter being My inquiries were directed to this placed between it and the spnovial issue.

To be a possion which I shall presently We have abduction, or a throwing of the lagon his admission he comtonal pain, increased at the internal laseral ligament, and we have the motion of turning it inwards prevented the notion of turning it inwards prevented to the external lateral ligament. We can

flex the leg to a considerable extent, but can tween the only extend it to little more than a straight have line with the thigh. The further extension is prevented by the posterior ligament of Winslow, which is considered by some as a have been divided into separate portions, continuance of the semi-membranosus, which contributes to form the inner ham-string. Besides, we have on the inside, two firm hands femur; and there are called the crucial liga examine the joint,

nothing like so strong a ligament.

the books which treat of the ligaments and did not suffer much pain when I make strictness, there certainly is a fibrous cap- the synovial membrane is muc solic covering the articulation, although not so distinct or so defined as that of the hipjoint. Thus we have a fibrous expansion, nature of the discuss. connected with the synovial membrane, be-

be ligaments which sween the respective ngaments which I make the property of fibrous bands, and where these are more distinct, that they under the name of "ligaments."

Diagnosis of the foregoing Case.-Well, of ligament, proceeding from before and now, I have mentioned that in the case bebehind the rough protuberance of bone, forc us there is inflammation of the synovial on the middle of the articulating surface of membrane, with increased secretion of sythe head of the tibia, to the condyles of the novia. How is this distinguished from any other disease? Perhaps when I have related ments, from their heing placed across each some other affections of the joint, you may other. These ligaments perhaps assist in understand it better; but, in the first place, preventing extension of the leg beyond a 1 may state that the mere awelling, and certain degree, but they will very much pre- the shape of the swelling, were sufficient to vent rotation of the condyles on the head of satisfy me that it was the disease which I the tibia; that is to say, if you attempt to have described, and that it was within, and twist the thigh inwards or outwards from not external to, the capsule. The swelling the leg, the anterior and posterior crucial appeared on either side of the tendon of the ligaments, sided by the other ligaments 1 rectus, and a little likewise at the side of have enumerated, will restrict such mother ligaments and a little likewise at the side of have enumerated, will restrict such mother ligaments. There is no particular enlargement corresponding to the for the protection and limitation of the situation of any of the ligaments. The motions of this joint; there are some others, joint, when examined by touch, gives an but their importance scarcely requires us to impression of elasticity, indicating that the occupy our time in adverting to them; nor tunefaction arises from the presence of is it necessary that I should describe to you fluid, rather than from solid deposit; and we at present the small ligaments which con- come at once, therefore, to a knowledge of nect the semilunar cartilages, for they are the disease. But on going into the history out of reach when we are called upon to of the case, we find that it has been produced by injury. Injury is a great deal Now the synovial membrane is within all more likely to produce disease of the fibrous these ligaments. It covers the articular ex-1 tissue than of the synovial membrane. The tremities of the bones, and passes some dis-patient has pain, and that pain is increased tance up in front of the thigh-bone, beneath at night. Now when we look at the intimate the tendon of the rectus or quadruceps mus-connection which exists between the fibrous cle. There is a little interruption, however, and the synovial membranes, we cannot to the strict continuity of the surface of the synovial membrane; that is to say, it does the diseases of the other. It is very rarely, not form a perfect sac, because of the attachment of the little process termed the one of those membranes. We are much ligamentum mucosum, which proceeds be-more likely to have isolated affection of the hind the ligamentum patellæ to the con-fibrons than of the synovial membrane; dyles, just in the same way as you have the because the vessels supplying the synovial ligamentum teres proceeding from the hip- membrane, pass to it from the fibrous memjoint, to be attached to the femur, although brane, therefore when disease is set up in the synovial membrane, it extends rapidly You will find, then, that there are ligation to the fibrous capsule. Just so should we ments on the inner, the front, the outer, and the posterior sides of the knee-joint, dura mater. Seldom does it happen that and that the synovial membrane is necessare we have inflammation of the dura mater, rily more exposed between any of those without the inflammation extending to the particular spets, than where it is covered by hining membrane. So, again, in pericarditis, the ligaments; thus is the case more espe-tically on the anterior part of the joint, to the serous membrane, and terminates in where no nucles pass over it, so as to assist adhesive deposit. Besides, as to the nature in protecting the membrane. In many of of this swelling. I found that the patient articulations, there is no mention made of pressure over the ligaments, but when the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of this joint; but, in came to make pressure over the party of the fibrous capsule of the fibrous came to make pressure over the party This is not a very

esult of injury, for injury more free produces affection of the Spirits at was therefore induced to inquire into the robability of there being any specific cause if the affection; for the disease, as we very vell know, which is generally called "go-torrhozal rheumatism," affects particularly he synovial membrane of articulations. I rave been consulted lately upon a case very ilustrative of this kind. A gentleman has seen for some years the subject of disease of he urethra; and in spite of all he has sufered, he will go on subjecting himself to resh attacks of discase, and almost as often is he is imprudent, so often has he gonorhea. As soon as the inflaumation is set ip, and almost as soon as the purulent discharge is established, he has affection of the lifferent articulations; the synovial mensranes become inflamed, they pour out recretions, and the joints become tunid, mst as in the case before us. So that this lisease, you will observe, is frequently conaccted with a gonortheal or what we may call, if you please, a venereal mint. I therefore made inquiries in the present instance, and proceeded to examine the arethra, to iscertain if there was stricture; and at last, being satisfied upon all these points, and that the disease originated from pressure, and not from any specific influence of this sort, the treatment became simple; mere rest, with counter-irritation, having at once annihilated the disease. A comple of blisters were applied, he recovered the power of motion, without suffering, and was enabled to quit the hospital, in ten days or a fortnight, perfectly well.

CASE 2 .- Inflammation of the Synovial Membrane of the Knee-joint, with deficiency in its Secretion. - We have another case. where there is inflammation of the synovial membrane, with a deficient secretion of the synovia, there being an increase of the secretion in the last case. Elizabeth Herring, ætat. 14, a housemaid, was admitted on the 19th of the present month into No. 7, Lydia's Ward. She states that about a month ago, after kneeling, a swelling formed over the ligamentum patella. Probably she had the disease called the "ganglion patellar." The swelling was attended with much pain; and the joint became more painful towards night. Motion produced rather Leeches had been applied sovere pain. previous to her admission, without any benefit whatever; she had been going on in lischarge of her duties as a servant durgeneir application. Upon her admission a complained of sharp darting pain on the the knee. Pressure on the endele produced severs pain.

Le joint was attended with

Le gravation of her suffer-

as the was a slight swelling, which was painfultion of the special was tolerable; she rested which the pain, which was always worse then. She ic cause was put to rest, and had a blister applied to we very the knee, and afterwards a poultice.

The report of to-day is, that the pain in the joint is less; she has rested better these last two nights, and the swelling upon the ligamentum patclize is diminished. There is some slight crepitus still on moving the patella upon the condyles of the femur.

Whether there be any peculiarity in the form of the inflammation which gives rise, in the one case, to an increase of the synovial secretion, and to a deficiency of it in the other, it may be difficult to say. The same membrane is affected in both instances; there appears from the sufferings of the patients to be inflammatory action going on in both, and both are to be regulated on the same principles. This case has been for so short a period under our notice, that we are hardly able yet to ascertain what will be the ultimate result; but I have no doubt, from experience, having seen many such cases, that it will proceed just as favourably to a cure as the one of which I last spoke.

Cther Affections of the Knee-joint.—I have brought these different and somewhat to popolite cases forward, to enable you the hetter to comprehend the points of diagnosis which I have described; and I shall now proceed to the description of two other forms of affection of the knee, which are more rare, and perhaps more difficult to treat.

Besides the structures I have mentioned as contributing to the formation of the joints, - the ligaments, the synovial membrane, and the fibrous tissue, -we have the osseous extremities, which are tipped or covered with cartilages, the cartilages being lined with the synovial membrane. Now the ends of the bones, especially the cylindrical bones, which contribute so greatly to the support of the body, are enlarged. If the extremities of the femur, for instance, were not of greater diameter than that of the rest of the bone, they would be constantly liable to displacement, but Providence, wise in all its works, has, in the formation of the joints, increased the diameter of the ends of these bones; their bodies are of great compactness, and sufficient, under ordinary circumstances, to resist injury, whilst the extremities are exceedingly light, formed of what is called "cancellated structure; that is, small laming of bone, intersecting each other, and forming cells, which are lined with membrane, and which probably afford the secretion that we find in the cells of the cancellated structure. This part of the bone also is liable to inflammatory action, which may affect the power of th tellise there articulations, and may, indeed, eventually

lead to as serious results as happen from convenies any disease attacking the articulating sum immed as faces themselves.

that about a month previous to his admission, after taking much exercise, he experienced a dull aching pain of the right knee, which increased towards evening, and sirup of poppies, and half a pint of disof this mixture for a dose.

The affected limb was rather smaller than the other, for a reason which you will recol- cine, and the same form of tonic as that lect I explained to you at the last lecture,namely, that where there is disease, and the potasse hydriodatis; but instead of mixing muscles are not kept in exercise, they lose their contractile power, and become flabliv. He now slept well at night; and I ordered him to rub in, over the affected part, night over the surface of the knee. and morning, the unguentum potness bydrindatis, - an cintment made with a drachm of the potasse hydriodatia to an ounce of lard.

21. Much the same; joint rather diminished in size.

27. Pain gone; can walk without any in-

nd he wal presented well.

the Ou Structure of the Pemoral Parties of CARE 3. — Inflammation of the Osseous Structure of the Femoral Portion of the Structure of the Tibial portion of the Kate.

Knee-joint.—The next case is one of inflamjoint. The first is the case of Thomas station of the cellular structure of the con-Lynch, aged 21, living near the Tower, by dyles of the right semur. Many Chanten, Lynch, aged 21, living near the Tower, by dyles of the right semur. Many Lynch, aged 32, realding in Bermondsey, a married occupation a footman, and of steady habits, aged 32, realding in Bermondsey, a married woman, of secondary states admitted into No. 10, Lydia's Ward, on the 19th the line of the right semur. of November. She states that about seven months ago she received a blow on the right knee, from a fall, which produced considerable pain, but no swelling. The pain disturbed his rest greatly. Exercise of the joint increased his sufferings. Two small four months since, when the joint began to blisters were applied to the knee, but without affording much benefit. Upon his adaptive and the pain to increase. She then out affording much benefit. Upon his adaptive thick the activity of the pain to increase. continued more or less severe until about out afording much benefit. Upon his ad-mission he complained of pain on the inner repeatedly blistered, which, to a certain de-side of the right knee, particularly at night.

At the lower part of the joint, the inner side continued to increase. In a short time after-At the lower part of the joint, the inner side continued to increase. In a short time after-of the head of the tibia was found to be wards the limb became very large, and the much enlarged; and upon his placing the pain returned with considerable severity, foot on the ground, and resting his body on the limb, the pain was increased. He had internal use of the sulphate of quinine, the rheumatic pains in different parts of the symptoms again subsided, and she discon-body, and his general health was impaired. To procure rest and regulate the secretions, About two months ago, the intermspensary.

I ordered that he should take a grain of the authorizate of mercury, with half a grain and sometimes painful, although, until about of opium, and a blister was to be applied to a fortnight since, she did not experience the knee. By these means he rested, and much inconvenience, with the exception of the pain was somewhat relieved. In the stiffness of the joint, and pain upon con-beginning of October, the first blister having healed, a second was ordered, and, the secretions being regular, he was ordered to take the tonic mixture,—the mixtura portant health secretions being regular. tassæ hydriodatis. This is a tonic mixture admission, she complained of a dult aching which I frequently give, not only in such pain over the whole of the joint, which was affections as these, but in others, and with particularly severe at night. The motions great advantage. It contains a sixteenth of the joint, which are very limited, increase part of a grain of iodine, four grains of the hydriodate of potass, and a small quantity of the inner side of the knee—to the situation of the inner side of the knee—to the situation of the inner side of the knee—to the situation of the inner side of the knee—to the situation of the inner side of the situation of the si strap of popples, with a little distilled water, tion of the internal lateral bigament, pres-to each dose. The mixture is made of half so cases dose. The mixture is made of nail; condyles of the femur are greatly enlarged, a grain of iodine, half a drachm of the hy; condyles of the femur are greatly enlarged, driedate of potass, half an ounce of the and the partella appears to be sunk down arising of complex and half a pilot of his, and impacted between them. The general sirup of poppies, and half a pint of the health was good, the appetite was good, and tilled water; and the patient takes an eighth all the secretions were natural. Her general Oct. 16. He had now no pain on motion She was ordered to have the house-mediane than powers, however, are very much below par. which the last patient took, - the mistura lit with water, as a vehicle, she was to take it in the decection of sarsaparilla. She was likewise directed to have a blister applied

24. She arates that also is better, of saye that the pain is less, though still so at night. The tenderness on the l pain complained of on gra above the condyles,

Remarks on the C

ther rare affections; they are the articular recording the articular extremities of the bones which and the first formation of the knee, their in the articular extremities of any others. Still, I have seen the same disease affecting the elbow joint, and the lower extremity of the tibia, the ulna, and the radius. It appears principally

to arise in persons of scrofulous habit.

Diagnosis and Pathology.—From the histories of the cases, you must see that there might be difficulty in discriminating between the disease of the cellular structure of the extremities of the bones, and that of the synovial membrane. There is a dull aching pain, which is increased at night, indicating an affection of the fibrous structure; but on examining the joint you easily ascertain the scat of the disease. You find, probably, that the patient, as in the instances before us, complains somewhat of pain, aggravated upon pressure over one of the lateral ligaments. The reason is obvious. The articular extremity of the bone cannot be enlarged without separating in some degree the attachments of the lateral ligament, and thus putting the ligament upon a stretch which may induce a slight degree of inflammation. But the very figure of the joint will strike you as peculiar, and guide you to the rationale of the disease. When the patient is the subject of disease of the synovial membrane, with deficient secretion, he cannot have the joint moved without pain. because the synovia that unturally exists between the apposite surfaces of the bones is wanting, and they grate against each other, producing excessive suffering. Now in the instances of enlargement of the articular extremity of the hone. I have known i patients only complain of difficulty of motion, or of pain, when the limb was moved, from what they themselves called "a deficiency of the joint oil," meaning synovia; but in examining the joint I have found the patella move freely on the condyloid surfaces of the femur, proving that the synnvia was not deficient. How is the difficulty of motion of the joint, then, to be accounted for? Why in this way, from the articular surfaces having become altered, in consequence of enlargement, and the deformity thus produced. This is beautifully seen in the case of Mary Sollivan. The disease in her case affected the condyles of the femur; the extremity of the tibla remained as before, but the condyles were enlarged, the patella having mink down between them, and there become impacted; that even if she were to recover from the gain have the proper motions of the joint. from somewhat negative sympaccurate examination, and a plies of the joints, and of as detaining her here may cause her the hones, that yee have the more severe form of the disease.

You thus have all the symptoms explainad. Sometimes, when disease of this struc-ture has proceeded for a time, you have the periosteum of the bone becoming inflamed, and in consequence of its being expanded over the whole of the osseous substance, the suffering is extreme when it is pressed upon, just as you have pain in what is called " hydrothalmia," affecting the sclerotic coat of the eye. When that texture is pressed upon, it becomes inflamed, and is extremely painful. Of course the pain is less, in some degree, where the inflammation of the cancellated structure is slow: the only symptom of the disease then, is difficulty of motion. Where the texture is so delicate as the lining of the cancellated structure necessarily is, and when the inflammation which attacks it is slow, the disease is hardly evinced; but when the affection comes on rapidly, you then find, from the enlargement of the bone, and the implication of the membranes connected with it, that the character of the disease is much more decided, and can at once say that it is an affection of the fibrous tissue.

Prognosis.-What is the prognosis? In an instance where the disease has been of slow origin, and of slow progress, it is not likely that the patient will suffer eventaally, if proper care be taken, any further than from the irregularity of the joint, and difficulty of motion. Where once enlargement of osseous structure has taken place, you cannot diminish that extent of surface again by any treatment short of operative proceedings. In the first case the patient recovered under the treatment a lopted. The size of the joint somewhat diminished, and he was able to walk. Why was this? The head of the tibia was affected; there was a deposit taking place in the osseous struc-ture, the outer shell of the bone gave way, and the periosteum became affected and thickened. You can get the thickening of the fibrous texture of the periosteum reduced, but you cannot get rid of the thickening of the bone; it will remain so during life. In the other case, where there has been much more severity of disease, we shall have much more difficulty of cure. That patient has a scrofulous habit, and weak general powers, which are all favourable to the progress of the local affection, If she can only bear up under the confinement of the hospital, and the atmosphere which she will have to inhale here, I have no doubt that we shall be able to arrest the disease, and to send her forth with the me of the limb; but supposing the atmosphere, and the confinement of the house, do not agree with her, and her general health suffers, it will be prudent to discharge her, in order that she may have the benefit of better air. as detaining her here may cause her to have

What, gentlemen, will be the progress of

e disease if we do not arrest it? I preion of that curdy port of matter, w in scrofulous persons, we see deposited in instances of enlarged glands of the nack, filling, in great measure, the cancellated our next most structure of the bone. If we could cut through the condyles of the femur, and expose the cells, we should probably see some of them broken down, and filled with this substance. But if the disease goes on still further, you will have less of this curdy matter, and in its place a fluid generated, con-missing of that serous or indifferent sort of pus which we know to be the result of scrofu-lous inflammation. When this pus is formed, it will begin to make its escape by ulceration; the cellular structure will be broken down, the denser compact shell of the bone will gradually give way, the cartilages will ulcerate, and we shall have sinuses formed, from the interior of the bone, through which the discharge will take place. Very likely, however, before all this occurs in an hospital, the general health gives way, and we are obliged, with a view to save life, to get rid of the disease by amputation.

Treatment.-The object, however, is to avoid the resort to amputation; and I have, therefore, with a view to preserve the general health in such cases, given such medi-cine as is calculated to lessen the peculiar disposition to the disease which is termed " scrofulous diathesis." Indine has a re-markable effect in this respect; and I have which I spoke in my last lecture.

when once seen, and well examined, I do not think you would make a mistake between them and any other affection of the seine aware of them when they exist, you might mistake them for an affection of the synovial membrane, or of the fibrous tissue, and he led to give a prognomis which you could not afterwards verify, and which would be calculated to bring discredit upon you.

ha all these cases the utmost you can do is to arrest the inflammation, and put the parts into a healthy condition. You cannot produce an alteration again in the figure or diameter of the bone, which will restore its integrity, and reader the joint as St for the purpose of motion as it previously was. A lameness must always ensue where such an affection has taken place, and has given rise to enlargement of the bone.

Other cases we have under treatment, but I shall not to-day describe them. There bute to form i

CASE.

PRESUMED TO BE ONE OF

MECHANICAL OBSTRUCTION

TO THE

PASSAGE OF THE BLOOD IN THE ARTERIES.

To the Editor of THE LANCET.

Six, -The following case 'a part of which I read at the London Medical Society in Pebruary last! I think you will consider worthy of insertion in your valuable Journal. I am, Sir, your oliedient servant,

EDWARDS CRIEP. Walworth Road, Dec. 21, 1835.

Case.-Jan. 31, 1835. I was requested to visit Mary C., ætat. 22, of healthy par-rents, residing at Camberwell. She had cholera in March 1831, and says that " her mouth was slightly affected by mercary, but she speeddy recovered." tended her two years since, during a severe combined it with sarsaparilla, which is often attack of pneumonia, after which she had necessary. We have also employed the occasional cough, &c., fr sometime. She milder forms of counter-irritation; but if we has been at service for ten or twelve years, find that a decided improvement does not and generally, during that period, was able take place under blistering, we resort imboliately. as I shall do in this case, to the occasionally prevented from thong so by more powerful means of moxes, or issues, of headache and hysteria. For the last three or four days she has complained of pain in These cases are well worth watching. In-stances of the kind are not often seen, but heat of skin, &c. This morning there is pain in the epigastric region, rather increased on pressure. Pulse small, 50; tongue white, tig red; bowels confined. The menses have joint. Without knowing such cases, and appeared regularly, but the discharge has been small in quantity.

TRIAL OF MEDICAL MAGNETISM

AT WESTMINSTRE.

To the Editor of THE LANCET.

Str.-As I perceive with regret that my name has been alluded to in connection with mineral magnetism in your report of what took place at the Bestminster Medical public, crave a corner in your valuable PAROCHIAL MEDICAL ATTENDANCE. journal, to state a few facts connected with Society, I must, in justice to myself and the this subject. The virtues ascribed to mineral magnets by one party and denied by another, are, you are well aware, by no means new.

Dr. Schmidt asserts that his peculiar method of charging or increasing the power of the magnets is new, at least in this country, and his method of producing a north pole by a north, and a south by a south, while Drs. Paraday and Ritchie assert, on the contrary, that there is nothing new in the method; and as to the poles producing any other than these opposites, it is a complete fallacy, and both these gentlemen deny in the most positive manner the curative powers; and further, that no physiological effect can be produced by them, -that on

the living body they are totally inert.

But to enable Dr. Schmidt to prove the physiological as well as the curative powers; of his magnets, the Westminster Eye Hospital patients were offered him for his selectwo weeks, on Saturday the 12th inst., to the surprise of many, and myself among the Parliament."

Parliament. Parliament But of wha produced by the cold of the magnet. I immediately had a bar of wrought-iron, of nearly the same weight as the magnet, made in the form of a horse-shoe, and on Wedceday the 16th inst. In the Westminster Rye Hospital, Dr. Schmidt himself tried the effect of my har of wrought-iron on Mr. II. T. and on several other medical gentlemen present, when precisely the same physiological effects were produced on all. What carative effects may be reported, of course I have not the means of judging. In the above investigation I have had nothing for in the my object but an inquiry after truth, no person, no not even Dr. S. himself, will re-taics more than I shall do, if the magnets can be brought to our aid, if only in the unfair to settled yes

alleviation of the above you will very muc oblige that I remain, Sir, your very o By the in C dient servant, ROBERT DAVIDSON. Parliament-street, Dec. 29, 1835.

SCHEME

FOR REGULATING

To the Editor of THE LANCET.

UNCONNECTED as I am with any party in the profession. I have no besitation in expressing my sincere pleasure on perceiving a modification of your views as to the origin of the abuses now perpetrated in the rural districts, under the name of " Medical Re-

In the excellent observations contained in the leading articles of the three last Numbers of THE LANCET, you place the question in its true light. The blame attaches to the entire administration of the Poor-Law, and the Somerset-House gentlemen, as the head of that adiamistration, are the principal, though by no means the only offenders; nor is there any probability of redress until " the tion, and it seems that from eight cases of conduct of the Poor-law Conversationers and amaurosis, Dr. S. selected four of the most their assistants be brought before the consifavourable for the magnete. At the end of deration of the executive Government and

But of what use will complaints be, unless the Westminster Medical Society "that the we are provided with a remedy? Thompson might be tention, and to that of your numerous readers; and, even should it be altogether undesirable, will, I hope, be the means of calling forth more suitable and unobjectionable schemes of amendment. I propose, therefore, three principal measures.

I. That there be a certain and uniform remuneration for parish medical attendance.

11. That parochial surgeons he fully anthorized, in every case, to decide upon the nocessity of their assistance to sick par III. That the rate-payers of such

appoint the medical attendant of

let. As to Rememeration. Th of appointment by "tender," qualification of medical manifestly wrong, as

The Part words

ductive of transactions that its aboltion to the might be easily embodied in a scale similar character of the profession, that its aboltion to one proposed by Mr. Rumany, of Cheswould be hailed with estisfaction very revery medical man, except those infatuated specularity. The objection to a payment per case is, that lators, whose object is, at any risk, to occupy a point d'appui, from which to invade the practices of their previously established brethren. Nor is the plan adopted in some other Unions more defensible; viz. a certain remuneration offered, far below the previous expense of medical attendance, without any reason assigned, except that of "economy," and forced upon the medical residents under the threat of introducing one of the students, or half-pay surgeons, whose name, are on a list at Somerset House. Both these abuses would be removed by the adoption of a scale of remuneration, calculated upon the real cost of proper medical attendance. But suppose the principle of a fixed scale of remuneration were determined upon, several questions arise as to the mode and data of its calculation, and as to the persons by whom it should be calculated.

estimated by the total number of pumpers in the poor, to decide on the amount of remueach parish-or it must be by an average payment for each case of illness. The former appears most generally acceptable to medical men, and is proposed in an able pamphlet by Mr. Yeatman, of Frome: if adopted, however, the distance of parishes from the medical officer, as well as the seperficial extent of large parishes, must be provided for in addition to his plan.

But I doubt the propriety of this mode, for the following reasons . -- 1st, the difficulty of the calculation is much greater. Indeed, I know not exactly how a scale, containing a variation in the number of paupers, a varia-tion in the distance of parishes, and a variation in their superficial extent, could be compiled; and without either of these three items it would be imperfect as a guide to a fair and reasonable remuneration for the trouble and expense bestowed. 2ndly, the total number of paupers is not by any means always proportional to the number of met. 3rdly, disputes might often arise as to who are strictly paupers; since the regular paupers of the country are rapidly diminishing, as a distinctive class. And 4thly, it is probable that the administration of the Poor-law will reduce the number of paspers much faster than the number of patients who must be attended by the parish surgeon.

None of these difficulties present themselves with the payment per case; and it has the advantage of being recommended by sayment must, however, depend on the number of patients likely to be atthe distance of every patient the provisions of the Act on that bead to the distance of every patient that the provisions of the Act on that bead distance. These two condiments the three variations should elect their medical officer. This point medical of calculation, and is one, which is rather likely to be passed ded, and on the distance of every patient imprise the three variations

The objection to a payment per case is, that it is a temptation for the relieving officer to withhold slight cases from treatment. This objection is so valid, that it would be absolutely necessary to deprive the relieving officer of this power, before the plan were adopted. Then it would be unobjectionable. But more of this under my next proposition.

As to the persons by whom the calculation should be made, most certainly it should not be entrusted to the Poor-law Commissioners, nor to our own body, exclusively; but I think it might be fairly settled by the two parties in conjunction, that is, the country practitioners might appoint a certain number of deputies the fewer the better for the execution of the business), who should have power to treat with the Commissioners on the subject; or, what would be preferable, the Government might appoint some disinterested persons, whose attention may have been previously directed 2nd. As to the mode, it must be either to the expense of medical attendance for neration.

By whomsoever made, the scale should be in force only for two or three years, in order that unavoidable defects may be rectified, and unforeseen variations in prices may be periodically adjusted.

Srdly. As to the power of "ordering" medical attendance for the nick paupers. This must no longer remain in the hands of the relieving officers. It is atterly unjustifiable that these men, who in many instances are ignorant and unfeeling, necessarily absent from home during the greater part of their time, and anxious to curry favour with their employers by a rigid parsimony,—I say it is monstrous, that to these persons should be intrusted the delicate, important, and prompt decision, as to whether the applicant requires medical assistance. Almost all the coroners' inquests that have been held on neglected paupers since the introduction of the new Poor-law, have implicated the relieving officer.

It appears to me, therefore, that the medical officer must be the first referee in every case, nor should the sick pauper have to do with any other authority until medi-cal advice has been obtained. Some check would, of course, be required on the surgeon, to prevent the lavish distribution of relief to those whose circumstances do not entitle them to parochial assistance, and this might be arranged by a subsequent appeal to the relieving officers, or by the Board of Guardians declaring that the relief afforded is by way of loau, to be recovered according to

over as unimportant; to me it appears far otherwise; for even supposing that the first ineed as lateriers with the supervision and second propositions should be agreed to, which the Boards of Guardians, as the exceeding the laterier of the supervision which the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the Boards of Guardians, as the exceeding the supervision with the Boards of Guardians, as the exceeding the injustice and general injury, by the appointment of unfit and unacceptable persons to fill the responsible situation of parochial medical attendant.

Indeed, in proportion as the office might be made a more desirable one, so would a eystem of jobbing and favouritism prevail; more generally in these appointments. In a union of twenty or thirty parishes, the guardians cannot be expected to know the merits of each medical candidate, nor to judge impartially of the wants of each locality; the friends of the influential members of the board would, therefore, frequently be chosen in preference to the independent practitioners, who might possess no other recommendation than the confidence and good will of the parish in which they reside, — a recommendation which now often tells more against than for a candidate. Above all, the vile system of medical districts might still continue in force, for although the guardians would be unable to economize by it as they do at present, yet the mere wantonness of power, of more than a million of the human race, and the absurd fancy of simplifying their when suffering from disease, very properly arrangements, might lead them to appoint | reminded the profession, that the time is fast three or four medical officers, where ten or approaching when its members should agree twelve ought to be employed. These ap on some "almost unobjectionable plan," for prehensions are not merely speculative, but the removal of the gross defects of the prearise from a close observance of the work- sent system of medico-parochial relief. You ing of present measures.

Not only, therefore, as a preventive to sity of a change in the system, and that the these evils, but as due to the parishioners only question is, what are the principles on and to the medical profession, let each parish which the alterations should be made, and elect its own surgeon. The merits of the how they should be carried into effect? And, candidate will surely then be the only ques- finally, you have most judiciously observed, tion with the electors, and as no increase of that it will be of little use again to direct the expenditure would follow their exercise of attention of the House of Commons to the the right of suffrage, it is but in accordance subject, unless the profession be provided

should be extended to them.

The contested election between Mr. Cos- ledged. greave and Mr. Dunn, for the parochial It is now nineteen years since my senti-surgeoncy of St. Clement Danes, is a striking ments on the medical care of panpers were fact in support of my proposition. If four first recorded in the Medical and Physical or five guardians had been left to settle that Journal of London. In the year following or the guardians had been left to settle that. Journal of London. In the year following matter, it is just as probable that Mr. Dunn a plan was suggested by me for legislation, would have succeeded as Mr. Cosgreave, which was published by Longman and Co. although the latter was obviously entitled to The scale of medical pay, as contained hold the office, from "the humanity, skill, therein, was not, however, sufficiently grand industry, with which he had for nine duated, and was much toe high to be likely years discharged his duties in that parfah." to receive the sanction of Parliament, from Your remarks on that election were as just the which quarter alone any last and final secas its termination was fortunate.

put an end to the vexations and unsatis-factory mode of appointment now in vogue, contract system. Meanwhile, the to increase the respectability of the office, alluded to was distributed and and the prevent future chicanery and patronage, the rights of the rate-payres should be restored, and the parochial surgeon elected apite of expense and discourage

fauctionaries.

I have now, Sir, laid before you the heads of my plan, -there are many details which I refrain from troubling you with. Trusting to your liberality for the insertion of my remarks, I remain, at present preferring to be known only as, your obedient servant,

RURICOLA.

Dec. 21st, 1835.

PLAN

FOR REGULATING

MEDICAL ATTENDANCE ON THE SICK POOR.

" Da dextram misere," -- Vinc. Fa. lib. 6, 1, 379.

To the Editor of THE LANCET.

Sin .- You have, in advocating the cause truly intimate, that all concur in the neceswith the liberal spirit of the age that it with a remedy for the cvils, aircrady so fully made known, and so generally acknow-

its termination was fortunate.

Once more, therefore, I submit that, to From 1818 to 1834, I watched, with

and improved addicate was former, first inserting a copy of it in Tax Lancer for April, 1831, with a graduated scale, which cost me no little labour to construct. My plan, which embraces one uni-form system in the appointment and salaries of parish surgeons, consists mainly

of parish surgeons, consists mainly,
1st. Of a graduated scale of remaneration per head, and per hundred, of paupers, falling in price, in proportion to numbers, but below which rate of pay, no surgeon should be permitted, by law, to contract.

2nd. It recognises the principle of a comparatively minute division of medical labour, secured by appointing surgeons to parishes, or districts, in rotation (after two years' residence and practice), and limiting them to the care of two thousand panpers, annually, where medical men can be obtained in the immediate neighbourhood of the respective parishes or districts.

3rd. The contracts recommended, are to include casual paupers and interlopers, the treatment of compound and simple fractures and dislocations, and those attended under a suspended order of removal; no bill for extras being allowed, except for midwifery and trusses.

4th. It is also recommended that no pauper should receive medical relief, without an order from the proper authorities, unless in very urgent cases.

Permit me, Sir, to refer my professional brethren to No. 400, page 151, et seq. of your periodical, for the details of the plan alluded to, and to express a tervent hope that they will support it, unless they can produce one more worthy of their confidence, and of my humble but zealous assistance.

Many valued correspondents approve of the plan under consideration, while some propose, in addition to the salaries, so much per mile for journeys beyond the first mile. This item of pay, I apprehend, would be opposed in Parliament, because it would unsettle the amount of salaries, and open the door to real or supposed imposition. Surgeons would be suspected of performing more journeys than necessary. My experience, however, and close attention to the whole of this most important subject, induce me to recommend that the expense of drugs be defrayed by parishes or unions, instead of by medical contractors, the amount of which would be in augmentation of professional remuneration under my scale; and this probably might meet the views of those who think it too low, while it would remove all suspicion of paupers not being duly supplied with medicine. The medicine to be furbed by select vestries or guardians, with drice of the parish, district, or union paragraph by order of guardians or

attack, like the | stated hours, except in cases of emergency, when it should be done, as heretofore, at their own hopper and at their own expense. The mean of parishes has increased in author of medical monoplies, and, in the

same proportion, has rendered it impossible to discharge the medical duties, while many districts of unions are much too extensive for the medical superintendance of individual surgeons. The former miserably low rate of pay has been reduced in the districts and unions, and advertising for tenders is, in effect, farming out the care of the sick to the lowest bidder. In short, the well-known evils have been very recently multiplied and aggravated.

In defending the appointment of young surgeons, immediately from the schools of medicine, the Poor-law Commissioners speak of the superiority of their education, as compared with that of their elder brethren affirming it to be equivalent to the experience of the latter. But this singular argument, applied only to one of the de-partments of medicine - midwifery - will lead, if acted upon, to inhumanity and death: since in difficult cases of childbirth (about which alone, parochial, district, or union surgeons are consulted by midwives), nothing short of experience will enable them to overcome the difficulties of the case.

Another error of great magnitude has been committed by the commissioners, its advising guardians to pay surgeons so nuch per patient, instead of per pauper, per annum. The relieving officer, knowing nothing of the insidious approaches of disease, will, in numerous instances, refuse orders for medical relief, except in obviously severe and protracted cases of illness and accident. And it is frightful to contemplate as to what may become of pauper sick, after the half-crown fees, per patient, shall amount to the former salaries, for attendance on whom the district and union surgeons are not to be paid one farthing.

To amend the law regarding the medical care of paupers, will be as great a benefit to parishes as to the sick and hurt poor, since the latter, being more skilfully treated, will sooner be removed from the list of those receiving parish support. How many cripples, blind persons, and individuals unable to work, have remained through life a burden to themselves and parishes, in consequence of medical neglect, and the bad ranagement of fractures, dislocations, and dissesses of the eys, and of those numerous chaosic forms of disease, the victims of which might have been restored to health and profitable labour, if duly supplied with medicine and advice in the earlier stage of disease! How many parents have died, who might have been saved under a better system of the room to be in a convenient modical relief, and whose families have been Militich the surgeons or their as-thrown on their parishes for support! To come dispense the medicines, at say nothing of the impulses of humanity, a

change of system may be truly advocated in Parliament, in accordance with economy. No pecuniary saving will result from leaving one portion of the pauper population to the care of medical contractors, at 35, 36, per patient, while another portion is to depend only on the eleemosynary aid of medical practitioners, notwithstanding the fact that their services in this way are beyond all praise, services performed like those of the illustrious Boerhaave, who declared the poor to be his best patients, because God was their paymaster.

I remain, Sir, your obedient servant, J. C. YEATMAN. Frome, Somerset, Dec. 28th, 1835.

THE LANCET.

London, Saturday, January 2, 1836.

Ir may suit the feelings and objects of certain mischievous insps who play their tricks in the temple of bigotry in the Strand, to allege that the professors, the Council, and the proprietors of the London University, or, as it is hereafter to be called, University College, have been endeavouring to obtain for that institution an all but exclusive nomination in the charter, which it has of a metropolitan university. The allega- equality of all the candidates for literary tion is a gross, unqualified calumny, so and scientific honours and distinctions. In far as the professors and the Council are taking this course the professors judged concerned. What may have been done by rightly, both as regards their own reputathe proprietors, generally, or by individual ition and the interests of the public. They members of that body, we know not; but it have honestly denounced monopoly, and is notorious that neither the members of the they courageously rest their hopes of suc-Council, nor the professors, have ever made cess for their pupils, on the abilities which any application to the Crown, or to the ex- they 'the professors; are capable of disecutive Government, for any, the smallest playing in the discharge of their duties. exclusive privilege, either for their own Besides, it must be recollected, that the act benefit, or for the advantage of the institu- of applying to the Examiners who are to be tion to which they are attached. When appointed by the Crown will be a voluntary they endeavoured to obtain the power to one. There will be no compulsion when confer degrees, neither in their petition, nor lever in the case. The student me in the arguments of their advocates before may not, become a candidate for \$1 the Privy Council, was a single fact stated, and it would be madness to support or an argument advanced, which had a tend- curriculum will be framed will

ency to three the there the merits of their contemporaries, or the claims of other bodies to legislative honours and protection. This position was assumed with perfect justice, and was maintained with boldness and consistency. The senate claimed for their pupils those honours which were awarded at other universities, and where higher, or more efficient appliances for the acquisition of such honours, cannot exist. There was not the slightest pretension to exclusiveness, in any one of their denunds; but having felt that they were fully capable of rendering their pupils competent to undergo an efficient examination in literature, in the arts, and in the sciences, they claimed the privilege of awarding university honours, under the sanction of a charter, because, and only because, there was no public examining body in the metropolis to which the candidates for university distinctions could be referred.

No sooner, therefore, was the proposal made, that an university should exist in the metropolis, under the sanction of a charter granted by the Crown, than did the proforsors of the University willingly say "content" to the principle of a scheme been proposed by the CHANCELLOR of the which would recognise before the Examiners Excuseurs to frame for the establishment of the Metropolitan University, the perfect

the effect of determining the proceedings at which | through its possession, over the proceedings a man must choose to become a capalitate of Smithfield market, Suppose that in that for university distinctions. This consider charter the names of two or three counties ration, as well as a multitude of others, in England had originally been introduced clearly points to the necessity of establish- as those of favoured places, and that no ing the University in this metropolis upon cattle were allowed to be sold in that market, the broadest basis - upon the most liberal unless they had been bred in the counties and well-understood principles. It would particularized, the charter requiring that he far better to be without any university "certificates" in evidence of that fact should in London than to create a new monopoly, be produced by the sellers, to the full satisthough a new monopoly would be created faction of the Company of Butchers, that no beyond any doubt, question, or cavil, if the deception was attempted, that no fraud on pupils of particular institutions are to be the terms of the charter was about to be selected for examination, to the exclusion of practised. Not one whit more glaring is all other applicants. What is it that the such an absurdity, and, probably, not half Government designs to honour? What ought the feelings of fathers, or friends, or uncles, Members of Parliament, have to do with appointments to hospitals? Until this wretched means of promotion is abolished, and the "concours" established in its place, expressions of complaint and dissatisfaction will continually attend all hospital elections. Had those who now repine with disappointment met in conference, and, like the surgeons of the hospitals of Paris, on a recent occasion, protested against promotion by the vile machinery of private interest, they would have deserved the sympathy of the public, and the support of the press; but so long as they consent to be the agents of a pernicious and absurd system, they caunot justly look for either. Now their complaints are only mocked. Their own corrupt inclinations, and the incompetency of even the that a large body sho best Government to decide with justice in pose. Ten or a dead

> We have selected for insertion in this week's Lancer, from several letters which we have received on the same subject, two able communications, (pp. 540, 542,) both containing schemes for regulating the medical contracts in parishes. Mr. YEATMAN has on several occasions discussed this subject with very great ability, and in the lotter signed " RURICOLA" there is evidence that the writer has devoted the energies of a thoughtful mind to the question which is now occupying so large a share of the attention of the medical public. A careful consideration of the contents of these documents, must lead to the opinion that no useful or final settlement of a "plan" can take place, unless the parts of which it is composed, receive the most della vestigation in the presence of of medical practitioners.

sen the capabilities YNATHAN, the author of the letter of RURICOLA," would be us well qualified to execute the task, as would be a committee of one hundred. But when the importance of the ulterior object of influencing members of Parliament is estimated, the more numerous the attendance, the more favourable will be the chances of carrying out the contest to a successful result. Should it be determined, by surgeons who are practising in the country, to hold a meeting in the metropolis, we would suggest the propriety of postponing it until within a few days the Bats that Mr. Liston was solicited to after the meeting of Parliament, at which become a candidate for the chair of surgery, time the members of both Houses of the lately vacant in the University of Edinburgh. results, by their medical friends. We hope published in The Courier, evening newspaper. that experienced practitioners will not be remains not only unrefuted, but is fully consparing in their remarks on the plans which firmed by some remarks which have been are this week proposed by our correspond. made in the Town Council at a meeting of ents. The subject, altogether, demands a very patient investigation.

cover of THE LANCET of December 19, in come a candidate, as the patrons were at which it was announced that a Dispensary that time looking out for a fit person to fill the surgical chair; and Mr. Liston then had been opened in Aldersgate-street for the said, that be would not forego his prospects treatment of poor persons who may be in London for such an appointment. Since afflicted with fisculous and other diseases of that time, however, having had occasion to the rectum. The founder and surgeon of know if he would come forward; in answer this institution is Mr. SALMON. On first hearing of the proposal to institute such a Dispensary, we felt inclined to question the propriety of adding another to the number of our, so called, "medical charities;" but on giving the subject a more attentive consideration, we are inclined to believe that this Dispensary, if it be conducted on the principles which have been set forth in the pro. spectus, will be productive of some important rantages, not only to the public but to the The practice of this institution. erved, is to be opened, withat of a fee, to all medical the profession will now ty of ascertaining whether

of Mr. I that class of diseases which is to be received for cure at this Dispensary, occurs with such searvellous frequency as has been alleged by some Heing authors who have written on the subject; or whether, in fact, increased experience, and further opportunities of obscryation, will not tend to confirm the suspicion which has long been entertained by many eminent surgeons, that this department of surgery has long been made a source of profitable and disgusting quackery.

Ir has been denied by the hired tool of Legislature might be visited, with the best The statement, however, which was first that body, and reported in the Edinburgh Weekly Journal. On that occasion Convener Dick said, that

" When Mr. Liston was lately in Edinburgh, performing an operation, he (Con-An advertisement was published on the reacr D) asked Mr. Liston if he would beto which, in a letter he had received, Mr. Liston stated, that an appointment to any chair in the University, would not induce him to become a candidate."

This declaration of course will set the question at rest in the minds of all persons who have not some knavish or malignant feeling to gratify. "But oh!" somebody may say, "the Council as a body did not offer the chair to Mr. Liston." Of course it did not. The experienced men of the North are more cautious in their proceedings than to take such a step. Individual members of the Council having ascertained that Mr. Liston would not leave London. the Council, as a body, reasonably enough, refrained from addressing Mr. LISTON on the subject. This is the whole of the matter.

THE LATE DR. WARREN.

DR. PELHAM WARREN died at his house in Berkehire, in the 57th year of his age, in Berkenne, in two and distressing filess, during the best of its assessment in an analysis of the first of its and legs of Physicians, though it was considered faithful friend, Mr. Pen nington. His death quite sufficient to enable him to practice what was occasioned by an abscess in the liver, they considered as the higher department of the liver, they considered as the higher department of the liver, they considered as the higher department of the liver. atrabilious temperament, and of a siender timate objects of attention for a pure phyphysical frame, and had a dark and pene- sician, were not so comprehensive as to trating eye. He was constantly taking allow him to make any addition to medical snuff, indulged freely in the juice of the science. Indeed, excepting one paper, which in his person. The circumstances, alto-lence was a predominant feature, made it concealed, he never even attempted to not surprising that he should fall a victim make a contribution for the advance-to hepatic disease. He was laconic in his had a great deal of devil in your face.

was considered to be one of the most capeta men in the trade, contriving to leave behind him a considerable fortune, as the result of 'This d—d morbid anatomy will speil the practice of physic." "knowledge of the world," as it is called, enabled him to secure for his son PELHAM an easy and safe path to successful practice as a London doctor. Educated in a school where bigotry had arrived at its acme, and corruption swayed unmolested, young WAR-REN had every opportunity of deriving the trary to their wish, and thus got for himself advantages which attend a classical, and the character of rapacity for fees what has of late been even more highly uppreciated, an Oxford moral education; and never having applied almself seriously to between Windmill-street and St. George's the study of medicine, or any of the scician, and to procure for him a cordial wel-come as a Fellow within the portals of the College in Pall-Mall East,—one of the most venerable and antiquated institutions in the have been sufficient to real empire.

With all his peculiarities Dr. WARREN allowing him alone to form the medical possessed some of the best feelings of human staff of the household, and obtained the than the imperfections of his character. Some mention being lately made of these in a private circle where the death of Dr. WARREN was the subject of conversation, a lady thus interrupted the conversation. "Ah!" said she, "speak not slightingly of Dr. WARREN. I knew him well. All my family in him placed the greatest confidence, and I know he had a tender heart. He long and kindly attended my beloved sister, who died of consumption in the South of France, whither she was sent in the hope of saving her valuable life. At his last visit she asked him many questions about the danger of her situation and her hopes of recovery, and after having given her the best answers he could, and left the room, my brother, unknown to him, observed him,

In the capacity of a Fellow Dr. WARREN was considered as the leader of a kind of opposition party in the College of Physiclans, that opposition, however, not having for its object any "rational" improvement in its constitution, but being aimed to dislags or to clip the wings of the President, and so losg ruled with sovereign sway the walts of that sanctuary. In most Dr. Warren was a Whig, any was deemed the me show

Many collateral manly and straight-ferward kind. His Maadvantages combined to introduce him, jesty had scarcely "breathed his last," when early in life, to a considerable extent of Sir Hanay hastened from Windsor, in the private practice; and for some time, eati-dead of the night, to Bushey-park, where mating him by his income, he was con- then resided the Duke of Clarence, to consulting physicians generally, diminished necessary worldly arrangements with Wilconsiderably. His illness, indeed, so mate- LIAM the FOURTH, and Sir HENRY'S persuarially interfered with his attention to busi- sive powers were such, that though the KING, ness of late, that, contrary to the opinion of prompted by the best feelings, had declared many, he left behind him but a very indifithat he would not change any of the nervants ferent practice for the aspiring generation of his brother, Sir Henry convinced his to succeed to.

Majesty of the "advantage to the nation" of nature, which it is more pleasant to notice royal promise to concur in all his recommendations. As might be expected, Sir HENRY, with his usual excellent discrimination, selected his own personal friends to fill every one of the appointments to which any emolument appertained, judiciously awarding to himself the most lucrative. From the position which Dr. WARREN at this period held in the College, Sir HENRY felt that he could not entirely pass him over in the new arrangements; yet he wished to place him in no situation of distinction. So, without asking Dr. WARREN'S leave, or saying one word to him on the subject, he gave in a list, and got it at once officially announced, in which Dr. WARREN appeared with the inferior title of " Physician Extraordinary." According to professional eti-quette this was considered both degrading standing at the top of the stairs, bathed in and insulting; so when this appointment was announced to Dr. WARREN, he declined the honour in the most contemptuous manner, emphatically declaring "that he would be d-d if he would accept any appointment from HALFORD," at the same time addressing a letter to Sir HERBERT TAYLOR, the King's private secretary, requesting him to cancel the appointment.

On another occasion Dr. WARREN dis-played similar feelings of contempt at the conduct of the President. When the ephe-The was deemed the se pass meral conversationes at Pall-Mail East [Birs-Birshes] and although Dr. were first got up, every means were adopted to results feelings and man; to procure a manufacture feelings and man; ings of action relief feelings and man to procure a crowded attendance, in order to show the influence and popularity of the

LECTURES

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE CRIVER-SITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE VII. CEREBRAL HEMORRHAGE.

(Concluded.)

GENTLEMEN, we have now studied rapidly the causes of cerebral hemorrhage, and have pointed out the several circumstances which favour the development of this discase, but we have not entered into the mi-nute history of each cause, a general view of the most important questions connected with diseases of the nervous system being the chief object of this course. Having thus deration of

The Symptoms which indicate the actual Rf-

cases they are merely the prodrome of the with a few anomalous phenomena that we hemorrhage which is subsequently to take shall have to consider apart; but before enplace. The patient is affected with head-acks, or giddiness, with numbness of the ask, can we have cerebral hemorrhage limbs, a disagreeable creeping sensation, without the manifestation of any symptoms? 26. In a word, with all the signs we have

12.5

by a violent effusion into the hemispheres. It is to this form that the term "apoplexy more peculiarly belongs. A great number of the symptoms of cerebral hemorrhage depend upon the actual effusion of blood; they are the result of the presence of a foreign body in the brain, compressing, or in a certain number of cases actually lacerating, the substance of that organ. Again, other phenomena that we observe, depend not upon the effusion which has taken place, but upon other morbid changes that coincide with it, such as ramollissement &c.; these form a third series. Finally, other symptoms manifest themselves, at a greater or less period after the occurrence of the hemorrhage. Thus we have occasion to see apoplexy complicated by the super-vention of ramollissement, of inflammation, of congestion, forming at several points of the brain, a long time after the first attack, and these circumstances, by troubling the march of the symptoms, by giving rise to various phenomena not connected with effusion, often render the diagnosis and treatment of cerebral hemorrhage a matter of some difficulty. Hence you see how several of the symptoms that accompany effusion of blood in the brain, do not depend on the hemorrhage alone, and can conceive considered the causes, we come to a consi- the necessity of distinguishing these secondary phenomena from such as are intimately connected with the original disease.

The Symptoms which indicate the actual Rf-fusion of Blood into the substance of the Brein.

These symptoms are such as to permit the in certain troubles in nutrition, relation, their division into several series. In some dy pointed out as indicating a greater currence of effusion of blood into the cereegree of cersoral congestion, and bral substance, is betrayed by symptoms comprised under the that leave no doubt as to the nature of the sion of "molimen henorsionally, the prementory
the to may be altogether possibility of cerebral henorrhage taking
these takes place with place without any of the great functions
the place of its approach, and
being disturbed. In proof of this 1 will county struck down quote the case published by M. La Nouman

in the Journal Heldomadaire, vol. 1, page 435. You will there find the case of a female. thirty years of age, who laboured under what is called the hemorrhagic diathesis, in a most remarkable manner; she had frequent discharges of blood from the mucous membrane of the intestinal canal; from the fauces and mouth; from the uterus; finally, tumours, evidently depending upon effused blood, formed under various points of the cutaneous integument, and the patient sunk under the exhaustion produced by this frequent loss of blood. After death a certain number of apoplectic coagula were found disseminated throughout the brain, yet this patient did not exhibit a single symptom connected with effusion of blood into the nervous centres. I do not know another example of the same kind in the records of medicine; hence, giving it the attention and regard it as an exceptional fact, as a case so extremely rare that it cannot justify the deduction of any principle.

We have distinguished the symptoms of cerebral hemorrhage into three classes, viz those connected with relation, with nutrition, and finally with generation; we shall sorbed, and the pressure thus removed. now take up the disorders manifesting themselves in the life of relation, and these comprehend derangements of the intellectual loss of muscular action coincides with the

Lesions of Motility. (Paralysis.)

The most characteristic symptom of cerebral hemorrhage is, beyond all doubt, paralygis: a sudden and permanent lesion of motility indicates effusion of blood into the cerebral hemispheres more surely than any other symptom we know of. Remark, however, that it must present the two characters we have just mentioned; the paralysis other. must be sudden; it must persist for a greater or less period of time. One alone of this is an important part of the subject. In the two circumstances is not sufficient to some cases we observe only a very slight indicate the existence of apoplexy; the loss engourdissement, or weakness of the affected of motion must have taken place in an ab- member. If it be the hand, the patient is rupt manner. When once established it unable to press an object with his accusmust continue for a length of time; with tomed force, although he can take hold of it these two characters we are justified in pro- with precision. The power of motion then nouncing on the occurrence of hemorrhage remains; we have simply a diminution of of the nervous centres; without these our the muscular force. In other cases the diagnosis should be given with some caution movement is modified in a still greater deand doubt. This diminution of muscular contractility exists, with various degrees of marked. Finally, in some cases motion is intensity, in nearly every case of cerebral completely destroyed, and the limbs are in a hemorrhage, we say nearly every case, for state of perfect paralysis. In a word, the the exceptions, though excessively rare, do sometimes occur; in a few cases no true paralysis has been observed, as for example in the one we have already cited. Another similar case has been published by Dr. tion of contractility SECRETIA, in his thesis on apoplexy, sus-may have no other trained in the year 1827. The subject of this do not present any observation died without having presented motility up to the the least trace of paralysis, and on examintack. In other cases, ing the body after death, a coagulum as large of actual paralysis \$

capying the pos-s at a hen a c misphere, above terior part of the think the ventriele, and extending thence into the posterior portion of the corpus striatum.

These are two very remarkable cases, I believe they are the only two which exist in the records of medicine; note them, therefore, with attention, and reflect on the curi-ous, the comprehensible circumstances of effusion to a considerable extent having taken place into the substance of the brain, without giving rise to the slightest derangement of the faculty of locomotion.

The paralysis once established, does it continue throughout the course of the disease with an equal degree of intensity? No; in some cases, even when effusion of blood to a great extent has taken place, the loss of motion, at first grave, may go off, and then return again with its former characweight it merits, we must at the same time ters. It is difficult to explain these intermissions in the principal symptoms of apoplexy. One would think these are times at which the blood acts with less force upon the brain than at others. However, in most cases the paralysis persists, and only goes off in proportion as the effused blood is ab-

We have next to inquire at what period the paralysis makes its appearance. The faculties of sensibility and of motility. 1st for instant of hemorrhage; it may suddenly acquire a high degree of intensity, and should a fresh hemorrhage take place, which is not unusual, it may augment. In general, however, it remains equable for some time, and then gradually diminishes; or it may increase until the patient dies, or, as we have already noticed, take on an intermittent character, and present itself with much greater intensity at one period than at an-

We now come to the degree of paralysis : gree; the weakness of the limbs is more lesion of motility may vary term capped ment, to a slight weakness of the ar-leg, and thence to be applete impossible muscular contraction. Be

- Tomas AND HEMIPLEGIA.

*patient exhibits a congestion: the matter, without semastin and without motion; sometimes modified, or we remark other troubles of motified, or we remark other troubles of motified, and the case is then constantly tility, such as convulsions contraction of the fatal; or, after having characterized the onlimb, &c; however, these latter phenomena announce the coincidence of another lesion, and we shall have to speak of them more fully in a subsequent lecture. The para-lysis, then, commences with the effection of blood into the cerebral substance, and disappears with the removal of it; whenever another order of symptoms sets in, we may presume that some other lesion of the brain, such as congestion, softening, inflammation, &c., have given rise to it.

Paralysis, the consequence of cerebral hemorrhage, variable, as we have just seen, in intensity, presents numerous varieties, according to the scat of the effusion. We shall now examine this point; we shall take up, successively, hemorrhage of the cerebral hemispheres, of the mesocephale (pons varolli, of the cerebellum, and, finally, of the spinal marrow, endeavouring, as we go along, to point out how far pathological anatomy can throw light on the great varieties which present themselves; and, first, for

Hemorrhage into the Substance of the Cerebral Hemispheres. - How does this form manifest itself? Hemorrhage of this portion of the cerebro-spinal axis may give rise to either general or partial paralysis; it is general where both sides of the body, either in totality, or in some of their several parts, are deprived of movement. Let us now see under what circumstances we may observe general paralysis. The loss of motion takes place in one of the three following cases: -1st. When the hemorrhage is double-i. e. when it occupies both hemispheres of the brain at the same time; 2nd. We may observe general paralysis, with hemorrhage into only one hemisphere; but the effusion has been very extensive; the blood has lacerated the parietes of the lateral ventricle, and thence made its way into the other cerebral cavities, either through their natural communications, or by laceration of the septum lucidum, and other parts; thirdly, and finally. When the hemorrhage, as in the former case, is confined to one hemisphere, and does not communicate with the ventricles: being, however, sufficiently extensive to destroy a great part of the cerebral mass, and then producing double parathe two cases already enume-

then are three causes of general wiz. double effusion of blood; but passage of the blood

se allied to so many masses of inert matter, without fatal; or, after having characterized the on-set of the disease, it may disappear in a certain time, and become converted into hemiplegia. Of this latter circumstance we have witnessed a few examples, and it often arrives in the third case we have distinguished above, where general paralysis exists for the first twenty-four hours, and then terminates in hemiplegia. However, we would here repeat a remark which has been already made, that general paralysis belongs much more frequently to cerebral congestion than it does to hemorrhage, and that in cases where hemiplegia exists, it is 200 to 1 that the loss of motion depends upon an effusion of blood into the nervous pulp.

When the paralysis occupies only one side of the body, we call it

Hemiplegia,

an accident, we again repeat, which, when it arrives suddenly, is the best sign of hemorrhage into the cerebral hemispheres. It then persists a certain time, and is gradually dissipated with the removal of its exciting cause. When it does take place, we generally see both limbs on the same side of the hody affected at the same time. However, hemorrhage of the cerebral hemispheres may produce paralysis of only a single limb; sometimes the superior, sometimes the inferior extremity being the one affected. When both limbs together are paralyzed, we generally see the side of the face attacked. at the same time, with loss of motion. The muscles of the cheek, lips, &c., cease to act, and the antagonism necessary for the regularity of the features being lost, whenever the patient talks or laughs the mouth becomes deviated, and the face more or less partakes of the distortion. Gentlemen, it is a law, almost universal in its operation, that hemiplegia (and also paralysis of the face) is seen occupying the side of the body opposite the hemisphere into which effusion has taken place. Authors have endeavoured to explain this remarkable phenomenon, which they attribute to the intercrossing of the pyramids in the medulla oblongata. The pyramidal bodies are, you know, continued through the substance of the mesocephale to the cerebral hemispheres, and hence the fibres of the right hemisphere pass to the left side of the spinal marrow, and vice versa. This appeared a very natural ex-planation, and was universally adopted by nearly all those who have written on the pathology of the brain. But permit me to lay before you one or two observations, by which, I think, its value is diminished if not here to the other through which, I think, its value is diminished if not altogether destroyed. In several cases where the extensive destroy when this general range a loss of motion in the muckes of the face opposite the seat of effusion in the brain. Now the muscles of the face are optic thalaction brain. Now the muscles of the face are optic thaleast and the state side. This obsupplied by nerves given off above the inter-servation is varied and attackness. We hence we cannot have recovered the ana-tomical fact for the explanation of a phe-nomenon that occurs at least as regularly, if not so frequently, as the paralysis of the we therefore think we must accept the law already stated, without explaining it in the manner generally adopted.

in the annals of the science; to supply the omission, which I only disce-

vered since our last meeting.
Two cases of hemiplegia, effecting the rife. ame side of the budy as the lesion, have at considerable length between Measure been published in the Bulletin Clinique, by SERREN, PEREL, GRANDCHARY, ROSTAN, M. DECHAMBER, of Salpetrière. They are and Houseland; we may therefore ask ouraccompanied by all the details necessary to scives, give them authenticity, and merit our attention on that account, as well as for the interesting points which they illustrate. The letion in the two cases alluded to was ramollimement; but, as we have more than once said, softening or hemorrhage, tumour or encrsted abscess, no matter; they bear all deavour to answer. Within the last few the same relation of cause to the effects we years, several facts have been published, with investigate. Our object in citing authorities the design of showing that the motion of is to show that paralysis does not universally the abdominal member is regulated by the take place on the side opposite the lesion, corpora striata and the nervous mass in front in adding these two cases to the thirteen corum, and the nervous substance behind already mentioned, we have a body of fifteen the thalami: in other words, that notion of facts, some of which, especially the latter, the leg depends upon the anterior part of are precious, because they are recent. In the hemispheres, while the posterior portion age we live in.

The same number of the Bulletin Clinique also contains a note of M. Founter on a case in which sudden death took place from effusion into the brain: the paralysis existed on the same side as the hemorrhage: this makes up the sixteenth case; however, the latter has not yet been published; the Bulletin Clinique alludes to it simply as having been shown to the Anatomical Society.

Paralysis, when it attacks the side of the body opposite to the hemorrhage, most com-monly affects both the superior and the inferior extremity at the same time : however, one is generally more affected than the other. We have remarked that the loss of movement is very frequently more complete in the upper extremity than in the lower. is a common thing to see the arm perfectly immoveable, while the leg and thigh are partially under the patient's control, and when the two limbs are equally struck in the commencement, the thoracic extremity generally recovers its motion some time before the abdominal one. In some cases of perethe homorrhage, the hemiplegia is con-fined to a single limb. The patient, for ex-ample, is unable to move his arm, while the where the inferior of

This point has been discussed lemin !

This is a question which we shall now enand for this purpose ramollissement will an- of them; while motion of the thoracic limb swer just as well as effusion of blood. Thus, emanates from the thalami nervorum optimedicine we require recent facts: the sci-governs the movements of the upper extreence should, as it were, be remade from time mity. We have submitted this opinion to the to time; for it is a principle in human na-test of facts. Here is the result we have ture to reject or look with coolness upon the obtained. We have collected 75 cases, in We have collected 75 cases, in ture to reject or look with coolness upon the obtained. We have collected 75 cases, in testimony of ancient facts, and run with which the lesion was circumverified in one avidity after more recent discoveries, al. part of the brain or other, and after having though, perhaps, they may be nothing but a analyzed these 75 cases, the result we came revival of points known many hundred years to was negative. In 40 of the 75 cases alludage, but fallen into disuse and obscurity, ed to, the patient was hemisleght: the arm merely because they do not belong to the and log were equally paralyzed. Now of the 40, we found the lesion situate in the corpora striuta, or anterior lube, in 21 cases: while in the 19 remaining, the hemorrhage, or softening, existed in the thalami optici, or posterior lobes. Again, of the 75 cases, we found 23 where the paralysis was limited to the upper limb alone. Now if the theory were correct, we should discover the lexions in the posterior portion of the hemispheres. What do facts show us? Of the twenty-three cases, we found two in which the lesion existed in the middle lobe of the bemisphere; eleven, with lesion of the corpora striata, or anterior lube; this remark is quite opposed to the ideas of the authors we have alluded to;) and finally, there were ten cases in which the lesion was seated in the optic thalami, or the nerve

pulp behind this part.
Thus you see how the same idlesion of motility coincided with a lesi various parts of the brain, and of the arm, at least for the The whether the effusion

i twelve ce and in two only of the lesion in the posterior Here, indeed, the nur favour of the theory which attributes me tion of the lower limb to the anterior less but one case is sufficient to destroy the va-lue of the rule, and we have more; we find, as you see, two cases of twelve where paralysis of the leg co-existed, not with a lesion of the corpora striata, but of the optic thalami and parts posterior to it.

The only general consequence we are entitled to draw from the facts which we have just passed in review, is, that dissimilar parts of the brain direct the movement of the different limbs, but that in the actual state of the science we cannot say what particular point of the hemisphere commands the motion of the upper extremity, and what point governs the lower limb. This is merely a negative conclusion, but we should not neglect it on that account. In the study of medicine, negative facts have their imporus wasting our time in the investigation of circumstances whose value has been already appreciated, point out various sources of error that we should avoid, and thus render our march in pursuit of knowledge more rapid, more secure, and more certain.

Is the faculty of motion deranged, when the lesion is confined to the periphery of the

When Effusion takes place merely between or upon the circumvalutions?

Certainly, gentlemen, we have cases where the lesion was strictly limited to the surface of the hemisphere, yet paralysis occurred with the same phenomena as if the blood had been effused into the centre of the organ. thesis sustained by Dr. Fasar in the year the whole of the lecture, a great part of 1832; it is I think No. 133 of the series for it being devoted to an address to students that year. Here the lesion existed at the lateral, posterior, and external parts of the left bemisphere; the author describes a congulum as large as a sparrow's egg, situate between the convolutions at this part, and the patient died paralytic. This case is not unique; we can find other examples. Similar cases are contained in the excellent work of M. LALLENAND on the pathology of the cain and its dependencies; in his first cain and its dependencies; in his first ster, page 63, you will find one; a second test, page 151; was completely confined to the man of the completely confined to the completely confined to the confined was completely confined to the confined with the hourselves, and the that hemorrhage confined that when the confined remarks regions.

the temperature minutes what may be called a direction from a distribution of the gray substance, we often do not abserve any paralysis; but, on the other shind, we have opposite facts to prove that when the convolutions are isfured, paralysis supervenes, although the white substance is little or not at all compromised in the lesion.

At the commencement of the present lecture, we said that loss of motion also ex-isted with effusion into the pons varolii, the cerebellum, or the spinal marrow. Let us next take up each of these parts in the order enumerated, now, however, only mentioning the mesocephale. We possess a certain number of cases in which we find

The Lexion confined to the Pone Verolit.

and we may draw from these this general principle, that the four limbs are rapidly struck with paralysis. However, in the science of medicine, we unfortunately find, at almost every step, certain exceptional cases which we are compelled to take into Thus, apoplexy of the mesoceaccount. tance as well as positive ones; they prevent phale is sometimes accompanied by bemiplegia, not by general paralysis : but in cases of this kind it has been remarked that the lesion generally is situate more at one side of the pons than at the other.

COOMBE LYING-IN HOSPITAL

DUBLIN OPHTHALMIC INFIRMARY.

THE Introductory Lecture, delivered, in the above institution, at the commencement of the present session, by Mr. ROSERT F. POWER, L.R.C.S.I., and one of the Masters of the Hospital, has been submitted to our examination, in manuscript. Want of space You will find an example of this in the in our columns will not allow us to insert on the importance of a scientific knowledge of his art on the part of the accoucheur; but we may select the following passages for publication, with a certainty of their posseesing interest for every class of medical readers. Before making the extracts, we may premise that on the death of Mr. O'Baza, the former " Master" of the hospital, the governors appointed two medical officers to fulfil the duties of the institution, which had previously devolved on one. The new masters were Mr. Powsa and Mr. HUGH CARMICHARI, the former gentleman undertaking the labours of the midwifery department, and the latter those of the Ophthalmic Infirmary. In the commencement of his lecture, Mr. Powns comments, of southilty, as when it in terms of Indignation. "on the attempt," as he describes it, " which has lately been did remark that when made" (by a magnate in the London Collegs of Physicians, before the Parliamentary where the stick.

those whose duty it was to remedy the crit.
"Since, however, the establishment, which we are assembled has been in operation, such truly pitiable occurrences have sltogether ceased, and with them those unfortunate results, then so prevalent, as the death of the infant, and recovery on the part of the mother with consequences so unhappy as to incapacitate her from the future fulfilment of her maternal and domestic duties. Indeed to such an extent did events like these prevail, that a respectable practitioner, who resided for a long time in this part of Dublin, at his death bequeathed an annual legacy for the establishment of a Lying-in Hospital in his district, after having spent the best part of his life in representing the necessity of such an institution to Government, but to which a deaf car was turned. Through the kindness of Doctor Bell, one of our most auxious supporters, and than whom no one is more conversant with the former miseries of pregnant females in the liberties, that legacy is now devoted to the support of this house, and the delays which used to lead to the events I have described, is remedied, a skilful pupil being now sent from this hospital to take charge of the female, and conduct her through her perilous situation."

CASE OF

OBSTRUCTION OF THE BOWELS,

WITH SUCCESSIVE OPERATION FOR THE

FORMATION OF A NEW ANUS.

To the Editor of THE LANCET.

Sin,—I publish the following most interesting case at the request of several medical friends, detailing the state of original imperforation, the means used for its remedy, and the time when the obstruction commenced, its progress, and the effects produced on the constitution of the patient until relieved by the operation which has led to the publication of the present article. The relation of the patient's subsequent condition, and the treatment, I have given its a condensed form.

I have added a few practical reflections, the stand to render it more acceptable to the members of the profession, and whom it is my more especial spaper should be useful. I

Charle Lempsay, Surg.

Case.—8. P., a boy, was born of healthy parents in April 1822, with imperforation of the anus. The surgest whose attendance was required; has several difficulties to contend with in making an opening into the roctam, as there was no protrusion of the first several attempts failed, but at length an opening was made at the lower end of the gut. Several attempts failed, but at length an opening was made at the lower end of the os sacrum, at the root, and towards the left side, of the os coccygis. The opening thus formed was kept patent by sponge tents and other means, but it was small, and liable to obstruction from slight causes.

On the recommendation of a friend, the child was first brought to me in December 1829, he being then eight months old. At about the same period he was examined by Dr. Weir, then senior surgeon to the Royal Infirmary, who recommended the use of bougies and enemata, which were accordingly had recourse to daily; the former were gradually increased in size, for the purpose of procuring a regular evacuation of feces and enlargement of the passage, which, with a few powders of Submuriatis Hydrars. ct Pule. Rhei, had the desired effect of improving the general health. Notwithstanding, however, the feces were passed involuntarily.

In course of time the child became a stout healthy boy; but when running about with his companions, having no power of retaining his fecce, they were constantly ooxing through the artificial anus, causing always a disagreeable smell about his person, although his mother, who was very cleanly in her habits, paid every attention to his comfort, by washing him frequently, for the couvenience of which the under part of his dress consisted of petticoats only.

The prospect of their son arriving at manhood under so loathsome an infirmity, was distressing and humbling to his parents, whose fears in this respect were, in the autumn of 1834, changed to feelings of a more painful description. At that time his health began to decline; his evacuations per anum were scanty, and passed with difficulty, even although rendered almost fluid by medicine. His belly grew large, while the rest of his body became emaciated; the functions of digestion became irregular and impaired; his appetite fell off; and, ultimately, hertic fover was superadded, which reduced his strength to such a degree as to confine him constantly to bed.

Such was his condition towards the end of January 1835, when I was desired by his fathor to visit him. He had now arrived at the age of five years and three quarters, and during the last four months his health had been obviously and rapidly declining. Language would scarcely describe the miserable appearance he presented. I no longer heheld the little plump radely boy which he for-held the little plump radely boy which he for-

painful contrast with his exceedingly one- the last hone of the secrem, rendered hope-

painful contrast with his exceedingly one-cisted cheer and extremities. Bestless any attempt at enlarging it, which was, Bestless the hectic symptoms, his mother: indees, he less desirable, as it would have mentioned that for several weeks previously left the justient to pass the feces involuntarily he had obtained no evacuation per annua as before. except what was produced by the daily use "all probe could be passed about two of the hougic and the purgative enerosts, including the position the boy was in at the state of the character means in when a little is the time, the noint of it being close moon acription. These symptoms led me to suppose that a flap, or false membrane, had under these circumstances, it occurred formed near the extremity of the rectum; to me that the most proper way of render-which, acting as a valve, prevented the exit ing him relief, would be by making a new pushed back by the introduction of the glys- tum, by that method avoiding the os coccygis ter-pipe. To ascertain this, I proposed to altogether. examine the parts with the finger, which I The objections to this were principally consider the best probe on such occasions. His mother's feelings, however, were overcome so much by the terror of cutting, that she even objected to allow the examination, danger of injuring the hisb of the urethra. especially as she considered his case to be therefore, continued, and by constant per- sacrum, I withdrew it. severance, they succeeded, at times, in On introducing my finger into the wound, bringing away a little feces, which had the and taking the probe in the other hand, I

Accordingly, on the ferce. I now pushed my fore-floger right day following, I visited him, at their resi- into the rectum, when a large quantity of dence, about two and a balf miles from Chas- feculent matter escaped. A mild purgative

Setting a table opposite the window, I had the little patient laid upon it, with his abdomen downwards, which was prevented from pressing on the table, by putting one pillow under his breast, and another under the head of his thighs. On attempting to introduce my little-finger into the artificial anns, I was surprised to find it too small re its admission, even although considerable ares use used, it being not larger than to allow a goose-quill to pass with sass. The integraments around it, which were very hard, appeared to be nearly destitute of either auscular or cellular substance, as if the parts were cicatrined after having been in a state of plocestion, which I was inforward had indeed been the ease. The pre- he personn.

heary imperfect, being merly was, and his extremely large abdo- sept established in the or coccepts and men, which were hard as board, formed a limited or conflict in the or coccepts and

the time the physter-pipe was in, when a little the time), the point of it being close upon The time the gramer-prise were m, when a little the time; the point on it being there is being the focus and matter excaped by the side of it; the cervits of the bladder, and about fifteen which generally stopped as soon as it was lines inward from the perineum. No flap withdrawn. Such, she said, had uniformly or false membrane could be detected by the seen the case during the time specified, alprobe, nor could any assistance be obtained though the dejections were of a fluid de-

of foces, except during the time of its being mus, nixteen or eighteen lines nearer the scru-

hopeless, connected, perhaps, with the dis- taining the probe in the old anus, I took a agreeable reflection, that although his eva- straight-pointed bistoury, and holding the custions were reinstated as before, yet still back of it towards the hulb, thrust it inthe boy's prospects for the future were any wards, about an inch. at that point where thing but pleasant. Purgative enemats, the raphe terminates posteriorly, and enwith the use of bougies of a small size, were, larging the opening a little towards the

On the 9th of February following, howenema was then thrown up, which brought away a great quantity more. In this evacuation there was a plum-stone, which the patient had swallowed four and a half months previous, during the fruit season in automn.

This stone, it will now be observed, I been the cause of the obstruction, any flap or false membrane, as I ha supposed. The stone, after personnels and intestines, had made ment by the eide of, a

us four menths as

is soccygis, from white the context of the hard and unyielding state of the parts, suc-rounding the artificial anus, and being greater in dismeter than the opening than it had been prevented from excepting. A If had been prevented from escaping. A constant tenesums had tormented the patient, while on every occasion of his goin to atool the stone, filling up the diameters the outlet, prevented any feculent writter from escaping, except when pushed back by the glyster-pipe, or a small bougle, as before stated.

Every experienced surgeon knows that in private practice it is rarely possible to get a patient to comply with all that is desired, especially in surgical cases, and it was so in this instance. The nature of his disease rendered the little patient peevish and fretful, and made him averse to be examined. Indeed, the first and only opportunity of examination was immediately before operating. The probe then slipping past the stone, as it was introduced, although turned in every direction, gave no indication of its existence, while the escape of a little feces, as before observed, prevented any assistance being obtained by the eye.

A piece of candle, four inches long, was new introduced as a bougie, and was secured by a pad and T bandage, the abdominal part of it being made of flannel. This was about one o'clock p.m., on the 10th of February. At four p.m. of the same day, he had another large evacuation of feculent matter by the new opening; after which, a new candle bongie was substituted in place of the former, which was partially melted. He was then put to bed, and enjoined rest, with mild diet : he remained in this state until about midday of the 11th, at which time he had another evacuation by the new anns, from 388 of Ol. Ricini which had been administered that morning. A wooden bou-gic, made very smooth, of seven and a half lines in diameter, was now introduced, and was ordered to be kept in and out for four hours, alternately. The abdomen had by this time become pretty empty and flaccid; pulse 150; skin hot; otherwise the boy was in good spirits, and had passed urine twice within the first twenty-fours after the operation, quite freely, and without unessiness B. 17. The motions have been passes gularly by the new anus. He has been walking about daily since the 10th instant, by which exercise, a small quantity of feeslent matter is forced out by the old anus. especially when the howels are loose.

B. Nit. Argenti gr. xx; Aq. Distillat. ij: rolve. Inject a drachm into the old and morning and evening; a piece of lint well covered with Ung. Resinos, to be afterwards introduced, to produce in the first instance a rawness of surface; after which, the solution of Nit. Argent, being discontinued, Tinct. Canthar. Vesie. is to be substitut and the pledget of lint, with the cintment, continued.

This course was persevered in for several weeks, with very little advance towards closing up the first opening, the main difficulty in accomplishing which was, the manner in which it had been excavated or hollowed out (if I may use the expression) by the great pressure of feculent matter, previous to the operation being performed, which has made it like an inverted cone, the outlet being the spex.

Considering such to be the case, I thought the only rational way of closing, or, rather of filling up, the posterior opening, would be to treat it as a fistula. So on May 19th I divided the space intervening betwirt th old and new opening, with a probe-pointed bistoury. When for this purpose I sutroduced my finger into the new anus, t sphincter closed round it with great firmness, which convinced me of his being able to retain his feces by the new passage, if the old one was filled up. A piece of o caddice was introduced into the wound, and accured by a positice and a T bandage. A teaspoonful of paste, in imitation of "Ward's Paste," was applied three times a day, for the purpose of assisting to form granulations.

This course was continued long enough to convince me, that something else was necausity to be done before sufficient grame-lations could be produced for filling up the cavity, which desirable object was considerably retarded by the pressure of focus often times displacing the dressings.

This electron is highly recommended by Ba-paytren, who used it in case of fissure about the arms with decided advantage. See Leiter of March

June 26. Coarse green flax was substi-tuted in place of the lint, and covered well we may come at the same point, by cutting at each dressing with the following:— or placeding from the perineum, at the pos-lation. Resince 3); Pade. Canther. Veric. terior terior insting of the rapide, as before gr. xx. M.

Previous to the introduction of the flax at

comes in contact with every point of the cavity, and is with the lotion and mixture already producing copious granulations, which are springing up rapidly. His health is excellent; no feculent matter has come by the posterior part of the opening for the last fourteen days, and the pledget of flax, which is renewed every morning, and which I direct to be kept as much as possible towards the sacram, remains in from the one dressing to the other, without being displaced as before. The bougie is to be inimmediately withdrawn.

From that time he was allowed to walk about, and on August 26 the medical remeup, so that neither feculent matter nor flatus form diameter, nor is its clongation so comcould escape by it. Being now able to retain his feces at pleasure, he was dressed in male attire, a circumstance that pleased

him very much.

Remarks.-This case being brought to a introduce a few practical reflections, suggested by what is contained in the foregoing case, and applicable to those of a similar nature, although not intended to apply to cases of imperforation in general. Having waited for a day or two, or, in some cases, for three or four days after the birth of a child with imperforation of the anus, in most cases the integuments between the nates gradually protrude, and become of a livid or black colour, from the pressure of the meconium within. There can, then, be no difficulty in determining how to proceed. With the pointed bistoury we make an opening, and, enlarging it with the aid of a director, nothing further is necessary than to keep it patent, and attend to constitutional symptoms, until the infant recovers.

But in cases of imperforation of the anus,

where no such profrusion takes place, and where no other mark indicates the position of the rectum, we are beset with greater

difficulties.

With a view of lessening these difficulties, I would suggest proceeding as in the case of S. P., by making a small opening with a narrow bistoury, just large enough to admit the probe on the left side of the os coccygis. If, with the probe, we succeed in seaching the gut, it can easily be ascertained, by its hogany, or

detailed; after which, the small opening at the root of the ea cocoygie may be conve-niently closed up by adhesive plaster.

the dressing morning and evening, 3] of the inically closed up by adhesive plaster. following lotion was thrown in with a small a detention to these directions may, I consyrings:—II. Dececti Gentiane Ib iss; Acid. critical series and least the difficulty in making a proper than at first, in cases where Joly 21. The flax tent, with the ointment, the gut can be found, by piercing at the root of the coccyx; and we may rest assured, that we never can make an artificial anus in any other situation than the one here recommended, with a probability of rendering the individual comfortable through life. There we have it at the most depending part of the trunk, so that no sac can form beyond it. We have the probable existence of that essential part of the anus, the aphincter muscle, without which we cannot retain the feces; we have also the two nates, like powerful sentincls, both adding strength to troduced into the new annu once a day, and the passage within, and affording security from injury without.

For keeping the anus patent, after it is made, I would prefer the wooden bougie to dies were discontinued, in consequence of any other. The sponge-tent is irregular in the posterior cavity being completely filled its surface, and does not continue of a uni-

plete as is required.

The wooden bongie can be made of any size, or of any form required, and never alters its figure by use; unguents of any kind, with which it might he proper to cover it, adhere better to a bougie made of successful issue, it may not be improper to wood, than to those made of bone, ivory, or metal. It is, besides, an advantage pos-sessed by the wood, that it

never communicates the same unpleasant sensation of cold to the parts as is the case with any of the others, unless previously immersed in hot water, which render them unfit for receiving a coating of ointment, if thought neces-

Bary The kind of bongie which I have found to suit best is made in this form, very much like that of a candle, with a rim, or border, at the farther extremity, to prevent it from sliping in, the pad and bandage, without the aid of tapes, serving to keep it from coming on extreme length which I h

of too small, a new to at a very trifling expelle

For a tent or pledget, my experience leads sac to think that green flax is preferable to caddier. Flax accommodates itself with great accuracy to the surface with which it comes into contact, and by its roughness it provokes the formation of granulation while it is sufficiently soft to yield wand protect them when forming. The size of the pledget requires to be reduced from time to time, as the cavity fills up, until it is finally

rendered unnecessary.

It will be observed, in perusing the above case, that from the 17th of March until the 26th of June, the time was in a manner lost in vain endcavours to close the old anus; this partly arose from the size of the cavity being so wide as to always allow a large quantity of feculent matter to descend and displace the dressings, but principally from the actual inefficiency of the applications. Some little progress was indeed made, but nothing compared to what was afterwards attained, by the use of green flax, cantharides ointment, and lotion, the paste at the same time assisting in an inferior degree.

COLICA SPASMODICA.

FOLLOWED BY

INFLAMMATION,

TERMINATING FAVOURABLY.

To the Editor of THE LANCET.

Sin,-I beg to transmit the following case for insertion in the pages of THE LANCET. I am, Sir, your obedient servant.

MATTHEW GIBSON, Surg. Govan Haugh, Glasgow,

Dec. 22, 1835.

Case.-John Maxwell, aged 20 years. while engaged at work on the night of Thursday, December 18th 1634, and in a state of profuse perspiration, took a large draught of cold water, and at 10 o'clock, an hour afterwards, was seized with a pain in the abdomen, exactly over the region of the caput cæcum coli. By l a.m. it had increased so much that he was forced to leave work. On arriving at home he swallowed two ounces of Epsom salts, which were in the house, and in half an hour afterwards had a motion in his bowels, but felt no At six the pain had so greatly in-accompanied by a disposition to his friends requested that he

21, 10 a.m. Passed a bad night, has taken five pills ; no stool ; blister rose well. and thinks the pain is rather easier; pulse 96; other symptoms the same. Applic. catap. emol. ad vesicat. Cap. pil. col. duas

statim, et idem schib. q.q. 2d hor. 8 p.m. Has had the pills regularly, but no passage in bowels, other symptoms much

Monday, 22, 10 a.m. Has had the pills regularly since last night, and has had thirteen stools, which are feculent and of a brownish colour; the first stoel was about an hour after last night's visit; expresses himself as considerably better; the hand can be pressed on the abdomen with great freedom, except above the capat on-cum coll, which is still tender; pulse 86, soft: skin meist; still some thirst; no more vomiting; did not rest much, from purging. Contin. cataplasm. Discontin. omnia medic.

10 p.m. Has had no more stools, but continues easy; blister discharging. Quies,

Cras mane.

Tuesday, 23, 10 a.m. Pulse the same; has had several stools since last night, which are mixed with a flocculent kind of matter; tongue cleaning; still some thirst; in other

respects pretty well.

Wednesday, 24. Has had six or eight stools since yesterday; thirst diminished; blister nearly healed; scarcely any pain in abdomen; pulse 82; tongue nearly clean; beginning to feel a little hunger; ordered some mild soup. From this date he gradually continued improving, without the aid of any more medicine, his bowels being freely opened once and twice every day, and in four weeks he was engaged at his usual employment.

Remarks.- In this case, it would appear from the prevailing symptoms, that both the beginning and the termination of the bowels were in active operation. That the greater portion (if not the whole) of the small intestines were acting naturally is certain, from the retention of the larger part of the medicine, and the consequent violent purging which ensued after the subsidence of the complaint; and that the greater portion of the large intestines was also acting naturally, is equally certain, from at the end of the small or at the beginning leading circumstance in the history of this cum coli, which is proved by the pain com- swoke in the morning with a violent pain

What was the pathology of this affection? | " A month after this attack," poses all cases of colic to be? Or was it spasm, which Dr. Cullen's views would lead us to believe? Or was it a case of common inflammation?

For my own part, I should consider this to be a case of obstruction, not altogether, however, arising from constipated howels (although the patient had had no stool for two days previous), but, as Dr. Cullen would case is, that after a

milit contractor. I have arge draught of cold water ations had drunk whilst perply, his bowels being sluggish time, both co-operating tagether, by giving a sudden check to the perdration, and nervous system, and thereby bringing on the disease in question, which coded, with the severe symptoms which ensued, in inflammation.

CANCER OF THE UTERUS.

To the Editor of THE LANCET.

Sin,-The importance of clinical lectures above all other lectures is unquestionable, and all men of science who feel for the welfare of a profession which stands first in the scale of humanity, must rejoice in the adoption of a mude of instruction, which but a few years ago was unknown in the British metropolis. Much also are the public indebted to THE LANcur for the wide diffusion and the consequent practical benefits of such lectures, which, had they ever been delivered at all, would, without the efforts of that journal, have been confined wholly to the limited circles in which they are pronounced.

In THE LANCET of November the 7th, in the clinical lecture of Dr. Elliotson, a case is given of "Chronic Inflammation of the Uterus," which, when I read it yesterday, impressed me very forcibly with an opinion, that its details and conclusion might tend to lead to much practical error. "The next case," the lecturer observes, "is one of diseased womb, in Elizabeth Warren, aged the expulsion of the different enemata which 29, a married woman, without children. were given. Now the fact comes to be this; Now this is to be noticed, that she was that the complaint must have been either married and had no children." The of the large intestines. In my opinion the case is, that about three months previous complaint was altogether in the caput ca- to her admission into the hospital, she cum coil, which is proved by the point course in the hypogastric region, accompanied by and also from the observations previously "a severe hearing down." "She had menstructed regularly hefore, and very copiously." " which was the Was it a case of simple obstruction in that monthly period, "she had a profuse dis-part from constipated bowels, or a loss of charge of a black colour, containing large muscular power in the part, and consequent clots of blood," and this lasted "for five over-distention, as Dr. Abercrombie sup- weeks." On her admission to the bosnital. On her admission to the hospitale the uterus was found to be so diseased, as to induce a doubt whether it was not of rhous (cancerous) nature. Sheobia under the treatment adopted of mercurials with opinm), and in the temporary she from town, as "relieve"

Now a leading

ion the 12sh she at the second of the second

The neglect, then, of an exercian when under amendment, to ascertain when ther the uterus was then "solid and fixed," or softened and more compressible, has thus consequently involved this case in a supposed doubt as to its nature; and is doubt Dr. Elliotson concludes his observations on the case: "But I will not say at this moment whother the disease was simple induration, or scientist, in the modern exclusive sense of the word," all of which embarrassment might have been avoided.

The directly probable state of this patient was that which Dr. Elilotson supposes might have been the case, viz., that "the uterus had fallen anddenly into a state of inflammation," and the circumstance of her not having had any children—and having menstranted "very copiously "previously to the attack, confirms the probability of the opinion that there existed a predisposed state for such an attack. But, on the other hand, all the history and circumstances of the supposition of a doubt that in its then reported state, it actually partook of any thing like the nature of scirrhus in the modern exclusive sense of the word."

In my "Inquiry into the Nature and Action of Cancer," published in 1805, 1 attempted to show and establish, that sein-thus was the result of "permanently altered structure" and "acquired actions" leading to cancer as a secessary consequence. This doctrine was opposed to the then prevailing opinions, that the disease depended upon some "specific poison," some "leaven" or "ferment" or "formes," or some "animalculæ of an hydatid nature."

This doctrine, supported as it was by the facts connected with the origin and progress of cancer itself, necessarily slow in its origin, was generally admitted, and so far influenced Dr. Ballie at the time, as to induce him, when he published his third edition of "The Morbid Anatomy," to withdraw certain opinions which he had formerly stated relative to the precliposition of parts as being the produces the disease, when

speaking of the "scirrhous and cancerous stomach."

So much is stated in application to the

So much is stated in application to the case in question. There never was sudden attack the immediate result of which was scierter "in the modern exclusive sense of the word."

The morbid, the permanently morbid altered structure, must be the progressive effect of some former injury or disease of a part, wherever scirrbus or cancer exists.

In all this the late Dr. Denman concurred, confirmed as the concurrence was by his own able and extensive observation and experience. Scirrhus of the uterus was never known to exist in a menstruating woman of twenty-nine, and therefore could not have existed in Elizabeth Warren's case; but which state the diseased condition of the uterus would necessarily lead to at some distant period, if it were not wholly removed, or if the patient were not previously destroyed by some fresh attack of inflammatory ulceration of the organ itself.

All the symptoms of Warren's attack proved it to be inflommatory, -andden, and not previously slow and progressive. Her copious menstructions" previous to the attack, sufficiently indicated the state of things, followed, as it was, by the after "profuse discharge of large black clots of blood," which lasted for "five weeks," and by which nature herself very sufficiently and impressively pointed out the treatment for relief, and which was adopted in this case, but in part only, and not completed. She was "relieved," but not wholly so. The treatment, therefore, as a case, was un-finished, and here was the error. The patient should not have been discharged as "relieved," but the state of the uterus absolutely ascertained by examination, the treatment continued, and the case not lost sight of, until the disease was wholly removed, or found to be incurable.

As these observations may be applicable to other and similar cases which may occur, I have thought it practically important to send them for publication, which, even if, Mr. Editor, you should not agree with me in my views, I yet claim, at your hands, upon the just principle which has hitherto influenced the conduct of Tag Lancer,—viz., that I may be heard, and, if wrong, that I may be set right, but if right, that that which is right may be established and promulgated. It is not, in this individual case of error, as I conceive it to be, that I respect Dr. Effects on less, but that I esteem the promulgation of truth more.

Amidet the labours of an extensive private practice, no honourable man can fail to entertake facings of respect for the public exertions of Dr. Elliotson in the general cause of science, which stand so pre-emimently in contra-distinction to those of that

FREE GASES IN DIABETIC URINE.

To the Editor of THE LANCET.

SIR .- For some months I have been much interested with respect to the free gases supposed to be contained in healthy urine, and have put the question to the test of experiment, by submitting the urine of different healthy persons to the action of my airpump, in the manner formerly explained in the pages of your very valuable Journal, but I was not enabled to extricate a single bubble of gas from any specimen of urine

experimented on.

Not deterred, however, by this, I was again induced to experiment on the urine of a sailor, belonging to this port, who had long been afflicted with that incurable and most severe disease, diabetes. This person, a dependant in the Sunderland Workhouse, came at two different periods to our infirmary, and in my presence passed twenty ounces of urine each time, in the most steady and correct manner, so that no gases were lost during micturition. The exact proportions of gases which ten ounces of this urine; ganese, put into a bottle which will hold contained at the first micturition, were as

Cabic Inch. .02 Carbonic acid gas19 Nitrogen gas

follows :-

From the second of the two micturitions, which was performed about five days after-wards, I obtained from a similar quantity of urine the following gases :-

Cel	Cabic Inch.		
Oxygen gas	.03		
Carbonic acid gas	.02		
Nitrogen gas			
	21		

I need not point out to the medical faculty the importance of these facts. I beg that they may be compared with what I have published in the pages of Tax Lancer, with respect to human arterial and venous blood. I remain, Sir, your most obedient servant.

W. REID CLAWNY. Sunderland, Dec. 24, 1835.

MEDICAL PREPARATIONS OF MANGANESE.

To the Editor of THE LANCET.

Sia,-Among the numerous metals which have been introduced into the class of medicines, I have never observed any prepara-tion of manganese. This metal is principally employed in the art of dyeing, and for chemical purposes, but I now wish to introduce it as a remedial agent. About two years ago I prepared a chlorine solution of that metal, and introduced it as an alterative and tonic, but afterwards found it a valuable medicine for epistaxis. Several remedies are now employed for this complaint. under the name of styptles, but I believe they are not to be relied on in severe cases of hemorrhage; and the acetate of lead is frequently objected to, on account of its irritating property.

It will be useless to mention the number of cases of epistaxis which have effectually yielded to the chlorine solution of manganese, as I have given the form for preparing it, and will leave the surgeon to judge of its application from his own experience.

To prepare the chlorine solution of manabout two pints, one ounce of carbonate of manganese previously mixed with three conces of distilled water. Let a current of chlorine gas be slowly passed immediately upon the mixture (by means of a glass tube connected with the retort whence the gas is distilled; until the manganese is dissolved. The solution must then be put into a flask, and a gentle heat applied for a short time, when the mixture will become clear. Filter when cold, and add one ounce of alcohol.

This process occupied a great deal of time, and was attended with some little trouble; therefore, instead of using the chiorine gas, I have since prepared a muriate of manganese, which is not attended with trouble, and its medicinal properties appear to be precisely the same. To prepare the muriate, take one ounce of carbonale manganese and two ounces of muriatio mix them together in a flack, and a treat of a lamp for a few m the mixture to cools file ounce of alcohol.

With respect to: of this medicine, 1 cient proofs to in its praise, but

proved a very good, antimony, &c. For itte e may be given, in combination with m rilla, with a very good effect. In some obstinate cases of chronic rhot also been given with advantage. The fol-lowing will be the best mode of administraing the muriate of manganese :-

As an alterative, tan or 60 be given twice or three times pe may a day in water. For epistaxis the same dose may be given, to be continued for a week or ten days, or antil a sensation of vertigo comes on, which usually takes place. If the hemorrhage continue for some time without intermistion, and the surgeon think it necessary to heck it immediately, give ten or twenty irops every quarter of an hour, until the pleeding stops, or until vertigo is produced, and continue its use for several days after. in every case which has yet occurred, the second dose has always succeeded in stopping the discharge, and without prolucing any subsequent unpleasant sen-lation. The muriate will sometimes proluce nausea, when the bowels are in a lisordered state; therefore a dose of some sperient medicine should first be given, if ime will allow, and also after vertigo is proluced an aperient must be given.

For hemoptysis this preparation has not et been given with success. However, it ias only been tried in two or three cases. When combined with Sp. Æth. Nit. and Inf. Anthemidi, it has proved serviceable in some cases of hematuria, but it must never

se given when fever is present.

By giving to the foregoing a place in your raluable journal, you will, Sir, oblige your bedient servant,

HENRY OSBORN, Chemist. Southampton, Jan. 5, 1836.

FOLLOWING.

SUPPRESSED FEELINGS or PASSION.

To the Editor of TER LANCET.

Sin, -I send you the following case, thinkng it worthy of a place in your journal; it scourred in the Hotel Dies, Paris, last sumwhere I was then studying. Your ot sgryant,

J. I. IRIN, Surgeon. Yorkshire, Jan. 4, 1836.

> tat. 35. tailor, of Paris, an affection of the

ary, states that he has been subject to violent pain of the head for two years and a half, but that it has become much worse lately, and that he had been totally blind for five and that he has seen totally mind for live months. The immediate cause of his blind-ness he attributes to a violent mental emoon, experienced whilst at a review of the National Guard, of which he is a soldier. Being strongly, and, as he considered, un-justly reprimanded by his captain, and not daring to reply to his superior officer, he was obliged to contain his violent feelings, in consequence of which partial blindness, attended with a strange sensation in the head, was the immediate result. This blindness rapidly became worse, and at the end of a month he was perfectly blind. For this affection, as well as for the pain of the head previously, he was repeatedly bled, both in the arm and the foot, and had cauteries applied to the head &c. but without the slightest benefit resulting.

His symptoms at present are, intense pain of the head, great heat of the sealp, watchfulness, agitation, vacant amaurotic stare, with dilated pupils, and numbress of the right arm, approaching to paralysis. Pulse 50, regular, but weak; tongue rather furred; appetite bad; akin cool; bowels regular; urine natural, and in proper quantity. Indeed it is only of the pain of the head that he complains. He answers questions rationally, though the other patients

state that he is occasionally delirious The treatment at this time employed by Dr. Recamier was very simple. It consisted in the constant application of cold to the head, by means of a tube communicating with a tub of cold water placed just above his head; the exhibition of purgatives, when necessary, and in keeping him on low diet. These means have not the effect of relieving his intense sufferings, though the sensation of cold, from the constant application of a stream of water to his head, is very agreeable to him.

I watched this case very attentively for a considerable time, but no improvement took place, at least with regard to the affection of his eyes. The pain of the head did, indeed, occasionally abate, but only for short times together. He grew exceedingly emaciated, and, finally, decided symptoms of mental derangement ensued, in which state I lost sight of him, as he left the hospital.

Observations.-Here we have a case of amaurosis which was decidedly produced by congestion of the brain, causing paralysis of that part of the brain from which the optic nerve takes its origin, the exciting cause being a fit of passion; the predisposing cause his sanguineous and plethoric temperament, apparently not hereditary, as he inwas admitted formed me that his parents were healthy old samier on the people. The congestion appears to have faction of the been of that form which is described by M. assesses. He Andrai as the "first seriety of coretral con-

gestion," in his lectures now publishing in structure. It is supply to guberty the body THE LARCET (and from the publication of and mamma were well formed; but the time, lost."

CASE OF ARTIFICIAL ANUS.

PRODUCED BY A LANCE WOUND,

CURED AFTER A NEW METHOD.

Related by Professor DIEFERMANN, Berlin.

A Polish officer received, in combat, a thrust of a lance in the abdomen : the blade penetrated up to the shaft. The result was a wound about an inch broad and two inches from the umbilicus, from which blood and excrementitious matter were simultaneously discharged. The patient's life was saved by an antiphlogistic treatment, but an artificial anus remained, which resisted the means used by several surgeons to close it. The whole circumference of the opening was surrounded with a hard cicatrized mass, whose long diameter was five inches, and its breadth two inches. The middle of this mass was occupied by a round hole, which easily received the tip of the middle finger: its inner edge was lined with the mucous membrane of the intestinal canal; probably the transverse colon. An examination of the cavity of the intestine showed not only that it was united to the abdominal parietes. but that its caliber was considerably diminished. As soon as the opening was uncovered the contents of the intestinal canal issued forth; while it was compressed with a printe and bandage they were retained. However, when the patient went to stook it was impossible to prevent a discharge of fecal matter through the artificial anus. After various unsuccessful attempts, the patient had recourse to a celebrated physician at Berlin, who thought he could close the opening by a milk diet, restricting the use of all solid food. The treatment had no other elfect than that of rendering the patient exceedingly thin. He now placed himself under the care of M. CARPIR and the author. The first care of the latter surgeon was to restore the patient's strength by proper diet &c. They then attempted to destroy the hard edges of the orifice with the actual cautery, but this means was also unavailing : an ill looking, pale, granular mass constantly shot up, which they could not get rid of. M. DIRPERBACH now determined on endonvousing to close the artificial anus with a ction of integument taken from the sound is; for this parpose he commenced by do a transverse incision of long, shove the wound, the of skin, two and this that WAR CORties only with

having arrested the hemovrhage, M. Dirr-PERBACH turned this flap downwards over the artificial opening, and united its edge with the lower edge of the circumference of the round cavity: here the two edges were united by a great number of small needles and sutures. The large wound thus produced was filled with charpie, to diminish the dragging and extension of the stitches. However, this experiment failed, the flap of skin died, and the granulations which sprung up were not sufficient to close the opening : the latter remained, although somewhat diminished. The author now proposed a method of treatment quite different; this consisted in destroying, with the actual cautery, the edge of the bowel united to the orifice of the wound, and also, at the same time, a considerable portion of the intestine within the orifice, sparing however, at each cauterization, the external integument. edge of the intestine was touched with the actual cautery the first day: a few days later he introduced a hot iron, crotchet-shaped, and as thick as a pen, into the intestinal cavity, and touched its parietes all round. This gave little or no pain, and was followed with a happy result. The opening was immedi-ately reduced by the rapid growth of granulations; and finally, after a treatment of nine months, the fistula was completely closed .-Kleinert's Repertorium, November 6, 1835.

CASE IN WHICH THE

ESOPHAGUS WAS INTERRUPTED IN ITS MIDDLE PORTION.

The Superior Moiely terminating in a Cul de Sac, the Inferior Opening into the Trachen. —Observed at the Hopital des Enfans Trouves, Paris. By M. Padiev, Interne.

A CHILD of the female sex, one day old, was brought and deposited in the "creche" of the hospital, on the 6th of August, 1835. Immediately after its reception the infant was seized with frequent vomiting: she threw up a sufficient quantity of bloody maccesity to induce the nurse to say the child vomited blood. On the 7th the vomiting continued. The matter ejected consisted in a very spurious miscosity, tinged of a rod colour from the blood. The colour of the 8th, some vomiting; the integuments are cold; the pulse excessively small; the respiration embarrance; face a little bluish; the drink taken into the mouth was rejected very soon after having been swallowed. Death on the 8th,

The amelioration continued for the seleving days: the See Muller's Archiv. fur Analousie. lochia now set in, and milk was secreted from the mamme; however, the wound did not present an appearance of speedy union; it was half open, and at the second dressing its edges were completely separated. The author, therefore, thought it best to heal by to suppurate; every thing went on well, and t was healed in less than seven weeks. During this period the woman did not suffer rom any of her former pains, and was carefully restored. The child died on the fifth seck .- Kleinert's Repertorium.

DESCRIPTION

THE ARTERIES

PAGAGED IN THE

ERECTION OF THE PENIS.

ANATOMISTS are not yet agreed on the nechanism of erection, nor in the manner ov Professor MULLER: -

M. Mexican distinguishes the arteries of he penis into two kinds, differing in their ourse, form, and termination. One act erves for the nutrition of the organ, the ther are the vessels which determine erecion. The untritious artery (arteria probada penis) passes to the apongy substance if the organ; its branches anastomose with ach other, subdivide, become finer and iner, and, terminating in capillary vessels, an no longer be followed by the eye. The rectile arteries (arterie helicine) are very hort and small, and are given off at a right men the larger and smaller branches profunds penis; they enter pens; they enter sitter and sither sit cal de sac, or by an analon, will that siving any either o, white giving any furcalling of the arteria are is sumed, not only ties, but also of which probably reis flaceid,

set in, viz., frequent ventiling and costive not numerous; the professor has not dis-ness. Some calonal, with an occasional covered them in the venous cells of the curema, was administered; this brought gians penis. These rectile beauches are away a quantity of fecre and wind, and the most casily discovered in man; less so in

CARR 2 .- Pauline Arnaud, eight years of age, of lymphatic temperament; with light hair; fine white ratio skin; eyelashes exceedingly long, &c. Her father and mother are healthy; she has not been affected during infancy with any eruptions of the scalp, or glandular engorgements. At the age of seven she contracted the measles; the erupn which the arteries of the corpora caver- tion went through its course with regulaiosa penis are distributed in the interior of rity, but left behind it some accidents, hat tissue. The following is a resume of in particular a catarrhal affection of the he researches lately made on this subject bronchi, slight, however, and never forcing the patient to keep her bed. In the year following the attack of measles, the cough was moderately frequent; headache from time to time; never hamoptysis or convulsions. On the 1st of August she was seized with malaise, vomiting, and a little fever. These symptoms persisted for three days. On the fourth she was admitted into the hospital.

Aug. 5. At the morning visit she presents the following appearances: - Embonpoint moderate; face a little flushed; decubitus dortal; cough not frequent; expectoration none; little or no difficulty of respiration; heat of the sk.a moderate; pulse 108; respiration 24; the tongue is covered with a light whitish for; the nauses and vomiting have disappeared; the abdomon is indolent and supple; the stools natural; no headache; the intellectual and sensorial faculties are Intact

Had the examination of the patient been

Author exertion, bercular meningitie, from page 695 . We continue our series of cases of tu \mathbf{C}

confined to determining the above symptoms, we might naturally have considered trunk still very well and the lit is imposher as convalencent from a slight gastric attack; but on practising percussion and auscultation we soon discovered the existence of grave disorders in the thoracic cavity.

Under both clavicles percussion grave and sound. The stethoscope revealed the presence of gargouillement and pectoriloquy in the most decided manner; the inferior pulmonary lobes alone were permeable to air. The disease was at once diagnosticated "pulmonary phthisis." A pectoral emulsion was ordered, and the patient allowed to take some solid aliment, as the digestive passages were in a good condition.

During the following days auscultation and percussion furnished the same signs as before, and confirmed the diagnosis. No change took place in the patient's condition until the 19th Aug. At this period diarrhora set in, accompanied by an access of fever every evening, and terminating during the nightain abundant sweats. The alvine flux was very obstinate, and resisted the employment of enemata with starch and narcotics.

On the 26th. The patient appears very dull, she refuses every kind of aliment. She answers the questions addressed to her with impatience. She avoids the light, and buries berself constantly under the bed-clothes. The pulse, however, remains calm. In the morning it gives only 84 pulsations. The respiration however is a little more accelerated; it is now 36. The abdomen is slightly tense, and painful to pressure; the chest is free from all kind of uneasiness; the patient complains rather of her head; no convulsive movement has been observed.

29. Profound alteration of the visage; alternating redness and paleness of the face; intense headache, forcing acute cries from the patient; vomiting. Sinapisms to the lower extremities. In the evening, convulsive movements of the muscles of the face and eyes; delirium; acute cries at intervals.

30. Deep prostration and suppor; pupils dilated and oscillant; complete loss of the vision; conjunctive injected; irregular movements of the globe of the eye; permanent rigidity of the muscles of the neck and trunk; resolution of the limbs; the sensibility of the skin is much diminished, especially on the right side; no trismus; no difficulty of deglutition ; face is pale ; abdomen supple ; diarrhosa persists; five or six involuntary evacuations in the twenty-four hours; skin dry and warm, is covered with sudamina over the front of the abdomon and chest; pulse 144, small and frequent; respiration 40, and unequal; no cough or expectoration. Blister to the neck; sinapisms to the lower extremities.

. 31. The patient's eyes still agitated by convulsive movements. She murmers every now and then some inarticulate words, without meaning or connection. The face is spinal matrey are as

trunk stiff very well states. It is impos-sible to place the child sitting up in bed. She is lifted up as if made of a single bit. The sensibility of the skip still obtuse at both sides of the body. The kimbs are in a state of resolution, except the right arm,

Sept. Text symptoms continue to present the raine character. The patient now lies in a state of complete coma. All the senses seem abolished except that of hearing. Twice we addressed a question to the little patient in a very loud voice, and twice she made a movement as if terrified.

2. Coma more profound. When the evelids, which had hitherto remained half open, but now are closed, are drawn asunder, the pupils appear a little contracted; the conjunctive are injected, and seem ecchymosed in some points; the cornea is dull; its surface covered with an albuminous exudation. The movements of the globe of the eye are less pronounced than formerly. Persistence of contraction of the right arm, and of the tetanic rigidity of the neck and trunk. Polse excessively accelerated, filiform; evacuations are involuntary; death at eight o'clock in the evening.

Body Examined 37 Hours after Death.

External Appearance. - Body but little emsciated; no cadaveric rigidity; anterior parietes of the abdomen present a greenish tint.

Cavity of Skull and Rachin .- Skull well formed; dura mater healthy; the glandulæ pacchioni seem small in number. Underneath the arachnoid which lines the convex surface of the hemispheres, exists a great number of granulations of a whitish-yellow colour, and varying in size from a milletseed to a large pin head. They are more numerous on the left side than on the right, and are chiefly confluent on the middle and external portion of the left hemisphere, and at the base, in the fissure of Sylvius. On the auterior and external surface of the left hemisphere, they are multiplied to such a degree as to produce small yellowish spots adhering on one side to the arachnoid, on the other to the substance of the gray matter forming the convolutions; the latter is softened with injection of its substance to the extent of an inch square, and to the depth of two or three line lateral ventricle contains alout of scrum. The fornix s of the ventricles are any change of colors. No al rest of the corestal mass; The pia mater covering the No alters presents granulations; organ and of the pre-The fibrous and an

able quantity of second estudies chord itself is perfectly normal.

Chest .- Adherence of both lungs to the costal pleurse. Each of the two superior lobes is occupied by a large empty anfrac-tuous cavern. The other lobes are healthy; we do not find in them any tubercles, either isolated or en masse. The larynx, traches, and bronchi, do not present any hing ro-markable. The bronchie fields are hy-pertrophied, but have not undergone the tu-bercular degeneration; heart and pericar-

dium healthy.

Abdomen.—Peritoneum free from alteration; mammellonnated appearance and slight injection of the mucous membrane over the great cul de sac of the stomach; the rest of the membrane is of a rosy gray colour, and does not offer any change of consistence. The mucous membrane of the small intestines is, generally speaking, pale; it presents some points of ulceration near the end of the ilium. Some of the mesenteric ganglia are tubercular. Numerous ulcerations exist in the crecum and in the colon; around the edges we detect a remnant of tubercular matter. The consistence of the mucous membrane of the great intestine is throughout diminished; the liver has undergone the fatty degeneration; the other viscera are sound.

P. H. GREEN.

LATE ELECTION

AT THE

RICHMOND HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

Srn,-Knowing that the pages of your invaluable journal perform at once the duplex functions of exposing medical abuses and suggesting practical remedies for their correction, may I, therefore, beg your attention to the subjoined statement of facts, which have produced much talk, if not excitement, amongst the politico-medical circles in this city, during the last fortnight or three weeks.

Mr. M'Dowell, a gentleman of much intelligence and indefatigable industry, who held the important office of Surgeon to the Richmond Hospital, fell a victim on the 7th tions to an over-test in his professional regits, which unfortunately outlived the wers of an endeut mind and a delicate resident mind and a delicate leave the melancholy ask of waiting the enlogy of man and excellent surgeon, pen than I can wield, and present by declaring

what the solate family have experienced an irreparable loss, society has been deprived of one of its brightest ornaments, and the surgical profession in Indiand of one of its most distinguished and independent members.

I need scarcely inform you that Mr. M'Dewell's death created a vacancy in the Hospital in which he was so efficient an officer. An inconceivable number of candidates for the vacant situation suddenly appeared in the "contested field," each putting forward his qualifications and claims to the best of his judgment, either by letter, proxy, or in propria persona, to the members of the Irish Government, with whom this appointment rests. Mr. Cusack Roney, the ex-surgeon, who in prophetic talents, in matters of self-interest, rivals Pastorini, in this transaction anticipated the uncompromising hand of death, and in what he no doubt considered a clever hit, sought by a very early, if not an indelicate application, through his friend Mr. Moore O'Farrell, M.P. for Kildare, and one of the Lords of the Treasury, that situation, for an ob relative, which was as yet the vested and legal right of the unfortunate sufferer, and for whose place, in excellence of character, it would be difficult to find a competent successor. Mr. White, of poor-law and cholera notoriety, employed as his advo-cate the cloquent Member for Tipperary, Mr. Sheil, who "could see no reason why his friend should not be appointed at once; he who had trodden the beaten path through the vale of years, and whose brow wore the indelible impress of the scathing hand of unsparing Time; in a word, he whose locks had not only grown gray, but had actually acquired an argentile brilliancy, in the cause of his country and suffering humanity." The Attorney-General, Mr. O'Loughlin, thought it would be no great compliment for the Government of which he is so distinguished a member, " to nominate his cousin, Mr. Kevin, who had been shamefully neglected, not only by former Governments, but by the public at large, for more than half a century." Mr. Trant's cause was ably advocated by his friend, Mr. Maurice O'Connell, the honourable Member for Traice, who stated that he spoke the sentiments of his father.

This was an unfortunate mistake in the learned gentleman's address; for, when he had concluded his oration, Lord Morpeth, by way of reply, slily drew from his pocket a letter which he bad received from the Liberator himself, in which he strongly recommended to his Lordship's attention another person, Mr. Lynch, whose capability as a clinical lecturer is but foe well known

to the pupils of the Jervis-afreet Infirmery.

Mr. O'Reilly was escorted to the Castle
by a Mr. O'Farrell, the M.P.'s brother, who ented death, introduced him to Lord Morpeth, as being said, discon- "the most efficient surgeon that could be found in Dublin," and at the same time as- rece sured his Lordship that " he spoke the sen- legit timents of his brother the honourable Member for Kildare, who would take the earliest to the Bioline possible opportunity of waiting on his Lordship, as he was much interested in favour of his friend the Doctor." Here a very and ward scene occurred similar to what took place in the case of Messrs. O'Connell and Trant. Lord Morpeth having listened with great attention to Mr. O'Farrell's statement relative to the deep interest which his brother took in the success of Mr. O'Reilly, smiled, and said, " This is really very strange, and then produced the letter pital, caused by the death of Mr. M'Dowell, which the Member for Kildare had written and that a Mr. M'Donnell was nominated to him some days previously, by solicitation in the room of Mr. Carmichael, who had of Mr. Roney, in favour of another person.

A Surgeon Ferrall was introduced to the Government through a petition from the Sinters of Charity, which was most numerously signed by the members of that community. The petitioners humbly entreated " that his Excellency the Lord Lieutenant would be graciously pleased to carefully consider the claims and acquirements of their long-tried friend the Doctor, and that he would look with an eye of benign conwideration on the object of their solicitude and maternal care, and that they would ever

There were many other candidates in the field, but as I am not well acquainted with their mode of approach to head quarters, I cannot pretend to describe with accuracy the particulars of their canvass, or the parts which they played in this truly ludicrous " comedy of errors." The Government find. ing themselves thus beset and besieged by a number of applicants of conflicting interests, yet all happening to be their supporters, felt desirous of getting rid of the embarrassing situation in which they were placed, of making an invidious selection of one from amongst many friends, had recourse to the following extraordinary expedient -They appointed Mesers. Crampton, Colles, and Carmichael, as a board of commissioners, and furnished them with a list containing the names of the candidates, from amongst whom they were desired to nominate the individual whom they deemed best qualified to fill the vacant situation. Well, the commissioners met, and met again, to consider and discharge the important duty confided to " their better judgment;" they felt puzzlod and confused, for the list was composed for the most part of Roman Catholics, and it contained none but reformers; they could not, therefore, conscientionally recommend any of the persons whose names were on the Castle list; but agreed to recommend to his Excellency's consideration a gentiernan, hir. Adams, who was not on the list, but who had the good fortune to be the political and personal friend of the impurish and arust-worthy delegates! Mr. Adams was fast, re

the sudac ed insulting protest, if is appoint med Hogil order to support the " che cal school of Deblin"!!! er of the medi-Although such a statement may appear incredible and prereaders of The Lawcer, yet it had " the desired enter; ? and, accordingly, in the course of a few days it was formally, and, I believe, officially announced in the newspapers, that " Mr. Adams was appointed to the vacancy in the Richmond Sure generously resigned to make way for his friend."

Thus ended the bungling and jobbing transaction, which in itself would be de-serving of little public attention, were it not for the extraordinary circumstances connected with it, and the rank and infinonce of some of the parties concerned. This given the whole affair a degree of seriousness and political importance, quite sufficient to set reformers of every class a thinking. In the first place, let me ask, what, in the name of common sense and common justice, could have induced the Irish Government, aye, and in this city, where party and political feelings run so high, and where partisanship and jobbing of the most flagrant and shameless description are deemed a legitimate part of the staple trade of the metropolis, to shrink from the firm and impartial discharge of its duty, and delegate the power and authority with which it alone was invested to three experienced jobbing intriguers? This may appear to those who know nothing of the former practices of the new-fangled commissioners, to be barsh language, but persons well acquainted with the intrigues of the medical profession, such as Cusack and Co., will readily un-derstand the propriety of its application, However, for the information of the uninitiated, I wish to justify my expressions, and illustrate their truth by a reference to facts which challenge contradiction. Mr. Crampton has, by a steady perseverance in that tact and managerism of which he is an accomplished master, succeeded in getting three of his own apprentices, one of whom is his nephew, appointed surgeous

to the Meath liospital. Amongst the numerous p ments of Mr. Colles, I have to tention to one which certainly be furgotten on the present of eighteen months ago, Mr. C ance with an agreem into by himself and. league, Mr. Cu Willy, appainte

Illabia was done. luminary whom the contracting parties deemed a suitable successor.

So much for the practices of two of the faithful delegates. As to Mr. Carmichael's

dik it prowess as an intriguer, I don't think it necessary to add one word beyond that has been already stated—namely, that he has been induced, within the last few days, to re- regarding Mr. Adams, I do not wish to be sign a post of honour on conditions best understood as speaking disparagingly of him known to himself. What could be more insulting to the candidates, all of whom were legally qualified to fill the situation, and of professional information, and that he is whose names were forwarded to the com- an honourable man. However, when I exmissioners, than to pass them by, and nomi- press myself thus, I wish it to be distinctly nate one of their own creation, assigning as understood that the conviction on my mind their reason for so doing the unblushing is, that he owes his present appointment Dublin?" This is not only an insult to the sorry to say that Mr. Adams ought to be medical teachers of Dublin, but a false re- classed with such rancorous bigots, both in usefulness he extended by his recent ap- Government. Oh, shame, where is thy pointment to the Richmond Hospital! In no blush! pleased to pursue in the exercise of their and place on their political enemies, to the high judicial authority, in treating with con- unjust exclusion of their own supporters! my success authority, in treating with con-ting distributions whose names were in-bed on the list which was sent to them and the success of the success of

cheers protegé of a reform Government! t doubt if a greater enemy to reform, or prized, by advertisiont, or otherwise, that doubt if a greater enemy to reform, or a his disinterested professesor had any inten-tion whatever of resigning in favour of the possibly be found in the medical profession then Mr. Adams. As a proof of the truth of this statement, I beg to apprize you that during Lord Haddington's ephemeral administration in this country, Mr. Adams was, on principle, appointed to a lucrative Government situation.

When I state these incontrovertible facts either as a surgeon or a gentleman. On the contrary, I believe he possesses a fair abare falsehood that it was necessary that Mr. more to the religious and political prejudiess. Adams should be appointed to preserve the of the commissioners than to his scientific respectability of the "medical school of attainments or private worth. I should be presontation in which the commissioners religion and politics, as Messrs. Harrison, betrayed their trust to the Government Jacob, et has genue owne, who take a pride which gave them power Why, Mr. Adams in declaring, on all suitable occasions, their and the learned commissioners would not be uncompromising hostility to the present lin, even if it were ordained by Providence tred to every thing liberal. By the way I that they should forthwith be translated have just heard that the veracious Mr. Harto another and a better world." However, rison wished to become a candidate for the

> there is no person more membered, both by Mr. Warburton and the Adams himself, that he, Government, should the premised Medical-the particular friend, Reform Bill lead to the establishment of a fine himself the harmony central board in Dublis, as persons who have, by their recent conduct, completely

disqualified themselves from atting or cooperating with any body of men whose duty and rule of action should be the exercise of impartiality and fair-play towards all persons, without reference to the religious or political opinions of any. Playe the honour the honour to remain, Sir, your obedient's vant.

OBSERVATOR.

Dublin, Dec. 30, 1835.

METROPOLITAN UNIVERSITY DEGREES.

To the Editor of THE LANCET.

Sin,-Having read two letters in recont Nambers of your Journal, on the subject of the remoured ministerial University, from students, it will not be thought, I trust, presumptuous in me, though but a country apprestice, yet equally concerned in this intoreating event, to say a few words on the

Thinking with your correspondent who signs himself " A STUDENT," that the plan divulged would be little better than a continuation of the certificate system (which enriches the few at the expense of the many), I wish to be considered as replying to some few of the extraordinary statements contained in the letter of the "King's College STUDENT." On seeing this signature, I was led to suspect something unsound, and my suspicions were increased, when, on reading the letter, I found a long account of the immoral tendency of students having to prepare themselves for examination, without compulsory attendance on "recognised" schools. Your correspondent seems to have overlooked one source of disadvantage to the student from the present plan. Are the morals of young men more likely to be endangered in country towns, under the eyes of their friends and relations, or when crowded together amid the temptations of populous and dissipated cities? It is not so much the love of mero pleasure, as a fond-mose for company, that leads young men into the excesses of youth. Your correspondent seems to wish, that no degree should be granted noises the candidate has obtained ertificates of attendance on lectures, when he himself allows that they are often prosured without attendance. " How many ' he exclaims, " who never show suscives in a instarr-room more than three or four times a week!" And yet these mag men obtain their "certificates." Why then should sertificates be required? Provided approbation, or ready to a student passes his examination, in course to any measures a quence of having acquired sufficient know- views of the old figs to enable him to perform the imper-m duties of a medical practitioner, what away come of

in he needed was honest govern ment?

The present system who tends to prevent the country practitions from raising little and above standardity, she has no inducement to devote sends time to the instruction of those pupils who are placed under his class, and who, after spending five years in comparative idleness (unless there be much dispending systemations), go to London attend dispending operations), go to London, attend the "recognized" hospitals, and there are professed to be taught their profession, while, in reality, the system in the end produces little more than the "fecs" which they are obliged to pay to the lecturers,not a harvest of knowledge to the students.

But, Sir, that part of your correspondent's letter particularly astonishes me, where he says, that if young men "were to graduate directly on coming to London, relying solely on their own exertions for getting through their examination, and without being put to any expense, being sons of farmers, tradesmen, &c., their graduation would detract from the respectability of the graduates as a body." This, in the nineteenth century, from a student of medicine and surgery! The gentleman, no doubt, is the son, or perhaps the grand-nessy, of one of the " big wigs" of the profession, or surely he would not write thus. Are men of enlightened minds to be refused the means of graduating, because, forsooth, they are sous of tradesmen and farmers? Surely the gentleman forgets bimself.

Praying that the cause of which you were so long the sole supporter, may soon trample down its great enemies, monopoly, prejudice, and self-interest, I remain, Sir, your abedient servant,

A COUNTRY APPRINTICS. Taunton, Dec. 18, 1835.

THE TUNBRIDGE-WELLS CONTRACT.

To the Editor of THE LANCEY.

Sin,-As I am the "individual" alluded to in the communication made by Mr. Way in your last week's LANCET, allow me through the same medium to state the rossons why " I alone of all the medical a objected to sign the regulations entered by those gentlemen who formed the m ing referred to. I did not, as is there a " decline from the first to act fessional brethren." On the op Way's house), perfectly wil in any arrangements whi

compensed, I was all acquainted with a nature of the resolutions passed; until the nature of the resolutions passes next meeting, when I read the included in the state of emerge two principals, an a large man the state of emerge two principals, an a have never before a ran as follows: ran as follows: - The me themselves individually not to outer into any contract with the Guardians of the Poor, for the whole or any district of a union, without the concurrence of Me Way, West, and Starling." ed mattion the Committee had an arranged mat-ters, that no one should, consistently with his honour, have anything to do with the parishes, excepting such portions of them as they, presuming upon their appointment. might be disposed to give up, being either at too great a distance, or not worthy of their notice.

When Mr. Way called upon and pressed me to attach my signature to the resolutions, which I had returned without signing, I objected to do so on the score of the third resolution, and was then told by Mr. W. (one of the Committee, that the consequences of my refusal would be exclusion from all future medical meetings, and that should I at any time require assistance in any case of emergency, it would be denied me by all the medical men in the place and neighbourhood. * * * It is further stated in a resolution passed

on the 26th of November,-"That the meeting express their deep sense of the apparent injustice which the Board of Guardians of the Tunbridge Union have committed in appointing a gentleman who had been less than four mouths in the district, to the charge of the sick poor of four parishes, which have hitherto for many years had the attention of five of the oldest practitioners in the place and neighbour-hood, who were willing, if required, to continue their services on the proposed terms."

• In reply to this, I beg to say. that although I have resided in the district only four mouths, I have, nevertheless, lived several years as assistant to one of the first practitioners, and in that situation have had the care of a part of the district. If the meeting meant, when they said, in their resolution of Nov. 25th, that the district had been formerly under the care of the oldert practitioners,- to convey the idea that the practitioners, I beg to remind them e pauper poor have been hitherto of those old practitioners; sting a minute in one of the completing in no measured at time received from an

> lesmat-terrace, Tunbridge Wells, December 23rd, 1823. 7, Maner P

"." To prevent a long and fruitless controversy on matters in which Mr. Sorwirm himself has not been placed in the situation of defendant, we have withheld from publication some passages in his letter. They relate to questions which are not really involved in the points at issue between Mr. Sorwith and the deputation.

THE CERTIFICATE SYSTEM.

To the Editor of THE LANCET.

Sir, -As I perceive from the letter at perceive 516 of THE LANCET, signed "A STUBBET. that the writer is willing to end the controversy, I shall, to prove myself actuated by a like spirit, forbear replying to many of his assertions, and shall content myself with laying before the public the following extract from a lecture delivered by Dr Elliotson, at the London University, being the first he ever delivered at that institution, and containing a most excellent programme of what a medical education should be. I myself was a much-pleased auditor, but any of your readers who have not read it, may had it at page 64 of the volume of THE LANCET in course of publication in October 1831. The extract is as follows :-

"The mode of instruction by lectures, though by no means sufficient of itself, is in my mind of high importance. When a whole subject can be taught in a solitary course of lectures, and the exhibition of nothing is required, so that a mere delivery of statement constitutes the whole task of the professor, there can be no doubt that a good work containing all the same information might be studied in private with equal beneal. and indeed with this advantage, that it would after probably costing less, remain in the possession of the student, to be consulted by him whenever he thinks fit. But when a circle of instruction is required, when the subjects are numerous, and demand many courses of lectures and many professors, th student cannot be committed to his Without lectures he would become also a cortainty bewildered, study at irre intervals, and wander from one sale another, gathering little fruit from interest, as well as a regu as shall which are of impalculable utility.

Such are the spinious of Dr. Ellicteon on this much-disputed point, and as he is one of the most talented members of the medicalreform party, these arguments, strengthened by the authority of his name, will go much farther towards producing conviction, than any I could adduce. I therefore far the present hid farewell to this subject, which I have not undertaken without pondering well over the following lines from Horace's book "De Arte Poetica:"

Bunoffe materians vestris, qui scribitis sequem Victimos un venste dis, quid farre reconent, Quid volume houveri. Cui lecta potenter exit res, Not hoppadis, deserct hanc, nec tueldus ordo."

That I was not inadequate to the office I undertook, is, I hope apparent to all. I have endeavoured to treat upon the subject with all possible calmness and moderation, and in retiring from the field of controversy, allow me to thank you for your liberality in allotting so much space to the writings of a political opponent. I remain, Sir, your obedient servant,

A KING'S COLLEGE STUDENT OF MEDICINE AND SURGERY. December 29th, 1835.

*.º Our correspondent commits a great error in quoting the opinion of any lecturer in favour of attendance on lectures, and on the propriety of rendering that attendance imperative on students. The question, however, is not whether certain courses of lectures may be advantageously attended or not, but whether the student shall be compelled to pay for certificates of having attended those courses, and many others.

REDUCTION BY A TWIST.

To the Editor of THE LANCET.

Sia,—Although dislocated hips may generally require pulleys and polling, yet the profession should knew that they will some-sines "go in with a twist." Last evening I was quietly taking my infusion of green tea, when "our hospital man," as my waitress calls a certain personnge, announced a dislocated hip taken into Gay's, adding that Mr. "Morgan was sent for." Knowing by dire experience that Mr. "Knowing by dire experience that Mr. Knowing by dire experience that Mr. Line of the command students assembled in the theatre, and an arundal system in the special and muffled men in a gray frieze cloak, handling ropes, palleys, &c. in the srea. A small candle personal in of a junto, would conscious countenance, and cast a dim religious light on the specialed and muffled men around. I special the gray man, the puny candle, the spectators, and the circle in the cares page of Tan La From half to there quarters of an hour with every seak

however classed, the find the became different, the discovered find at last the han in gray discovered. This is naciont gentlement with a broad-infinished particular, before the thourse and enoughed. Moreovered the thourse in reduced. Mr. Morgan bids me my that he extended the limb, and it went in with a terior.

with a twist."

I demanded to inspect the patient, and found him to be a man with a thigh like a life-guardsman &, and a beily to match. "Lucky fellow!" thought I, as I entered the case in my book, "to have thy dislocation go in with a twist! Enlightened students, to get such a clear and copious clinic, by proxy, on the case!" Your obedient servant, Mr. Editor, Q.

Dec. 24th.

The Dublin Journal of Medical and Chemical Science, January 1836.

Tur fund established during the recent summer for the support of Ireland's "only Journal," is not yet, it seems, exhausted. Another number has just come out, in which the causes of the expensive failure are still more manifest than on any former occasion. The communications called "original," by custom or by courtesy, we presume, are below the usual average of such contributions even in that Journal; the reviews exhibit the ordinary mixture of partisanship; and it is enough to say, with regard to the " nolities" of the Journal, they are by Dr. Jacob. But what opportunities for observation, what records of disease, or what talent in its investigation, could bring into favour in Ireland a work which is notoriously designed to promote the local professional advantages of the party by whom it was instituted and is supported? The feelings of distrust, suspicion, and contempt, which the appearance of each number of this periodical excites in Ireland, render the work a most inaut and uncongenial periodical for the circulation of scientific matter in the profession. Even had it the command of very numerous and able communications, which it com not, its character as a meant of the personal interests and of a junto, would ever name its utility and inflaence.

In November or subsection in the current or had pages of Tas La

Sutline of the su voted, and in physical eclerics such as that knowledge of the percussive responses in of medicine, when much personal cheerva-tion is implied, and a compendition, may in its proper place provides an adequate mutatitute for a more voluminous work. Manuals may be correct, though they cannot be full. A scholar's globe may be perfectly accurate, though it can present but few details of the face of the earth, and the stadent will gain much knowledge of geography by its use. Indispensable qualities in an elementary work are, correctness of arrangement, clearness of principles, and strikingly illustrative details. We will try the volume before us by these tests.

The science of auscultation, on its first introduction into this kingdom, experienced the fate of all important discoveries. It was received with almost universal ridi cule; but year after year the number of its disciples has increased, and, being dispersed throughout the various provinces of the empire, have propagated its doctrines so widely, that there are not now twenty men, - unless they be pure physicians and Pellows of the College,-who do not use the stethoscope in forming their diagnosis in supposed affections of the thoracic viscers.

In reply to the general demand for guides on this subject, almost the only work we have been able to mention with approbation, is the translation of Lacunce's work by Dr. Forbes, the cost of which is expensive. There are many persons, therefore, who, without our attempting to draw for them a comparison between the two works, will be glad to meet with the translation made by Mr. Pitzherbert, who states that the chief merits of the volume consist in the new matter which it contains, and the clearness with which the author has arranged all that is yet known on auscultaion and percussion. The author's preface we condemn, as full of erroneous dogmas. The translator should excise it in the next dition. The introduction forms an incerious essay on the utility of auscultation ne. The work itself is divided 1. The explanation of difmined by percussion and auss of particular diseases. ences, fully and satisall the regions of

to added they are the pricty of this accompanion is obvious. the healthy state, must precede a knowledge of their morbid deviations. Then comes a judicious essay on auscultation in general. In describing the normal respiratory sound, M. Raciborski controverts an opinion of Dr. Bean as to its physical causes :-

> " The friction of the air against the parietes of the bronchi and vesicles, appears to us, as it did to Laennec, the suppose its formation. According to Dr. Bean, the the resonance, in the whole colum inspired and respired, of the sound resulting from the pressure of this column against the soft palate and adjoining parts.' When the gutteral noise is suspended, says Dr. Bean, 'the trachesi and vesicular noises no longer exist, the respiration, although silent, takes place as usual, and if you did not feel under the ears the thoracic parietes retire and advance alternately, you might believe the individual did not breathe.' We object to this, that if there were no other signs of respiration but those afforded by the depression and elevation of the thorax, it is very probable that respiration did not take place, and that if it occurred without noise, it was because the air cid not arrive in suff cient quantity, nor rapidly enough to produce it; and that the reasons for which the tracheal and vesicular sounds did not exist, are precisely those which would hinder the formation of the guttural sound. As to our own experience, it has furnished us with results directly contrary to those of Dr. Bean. Patients required to breathe on a sudden, and therefore making more noise in the traches, have the respiration very slightly remarkable; on the other hand, the respiratory murmur, although feeble, has been distinctly heard in persons with whom the soft palate made no noise. But to meet with these cases, you must choose persons with whom the expansion of the lungs is habitually marked, or whose respiration is puccile. Although Dr. Bean pretends to have heard normal respiration, by blowing through a tube of paper against the soft palate of another person who held his breath, we have tried the same experiments several times, without producing analogous results. Most commonly we have heard nothing in the chest, but sometimes an acho of the noise produced in the throat; echo, however, had no similarity to the murmur of respiration."

M. Raciborski's remarks on the asseults. s evidence afforded by these tion of the respiration and the voice, sally with our own conclusions on the subject We quote the following moroscur relati to the more interesting assemb

"When a cavern bursts in the cavity of of the cavity. These was, by falling upon the pleurs, this cavity contains a collection of liquids proceeding from the broken on analogue (similar) to the produced by the verm, or afterwards secreted by the inflamed of liquid. In this case asscultation will feel of adapt of wasping and contain containing the cavity of the feeling of liquid. This quently dotted in the cheek, a particular results of the feeling of t quently detect in the chest, a particular noise, called by Laennec tintental matel-tique. The father of auscultation attributed the fintement metallique to the vibration of the air at the surface of the liquid, when the latter is agitated by the respiration, the voice, or coughing. Dance brings forward the following opinion with regard to the formation of this noise. When the level of the liquid, contained in the cavity of the plears, is superior to the orifice of the cavern, the air which enters at each inspiration into the lungs, rushes into the cavity of the pleurs, rises through the liquid in the shape of a bubble, by reason of its specific gravity being less, and arrives at the sur-face, where the bubble breaks, and produces the tintement metallique,

This observation had passed unnoticed-It is only lately that Dr. Bean, without being aware of the coincidence, happened to suggest the same ides, which he explained and verified by numerous experiments.

"The tintement metallique, for which Dr. Bean has substituted the term tintement bullaire, may, according to that writer, be equally well heard during expiration, coughing, talking, and expectoration. In fact, he observes, although in these acts the air be expired instead of inspired, still in the majority of cases of the presence of caverns, the surrounding part of the lungs is hardened, and does not collapse during expiration, the air expelled from the rest of the lungs rushes from the traches into the open bronchi, and from thence acts as air in-spired. Most generally this noise follows each act of respiration; sometimes, however, it takes place slowly, which seems to arise from the circumstance, that the bubbles before bursting may stop some time at the surface of the liquid.

"According to Dr. Bean, the same noise is sometimes heard in large caverns, filled in a great measure with liquid, and in hysumothorax, without any communication with the respiratory passages. But in these two circumstances, it is difficult to enceive the formation and supture of bubbles, and we must admit, in certain cases of tintement metallique, the simple explanation of this sound given by Lacanec in the case pared to the plaint of a gewhen it accompanies the repture of caverns name of topphonic.

into the cavity of the pleura.

"It happens frequently with patients in Tegeshonic is in uncertain these conditions, that when they change a tainly not always easy? I horizontal for an upright posture, drops of liquid, adhering to the plengs, or retained by hame the distinguished. uid, adhering to the pieura, or retained by may be disting se membrance, become separated from the "When the mem of liquid, which falls to the inferior part over a meet of

"The cases in which the fintement metal-Mose is observed, systems another phenomenon. Whenever the cavity of the pleura, or a higher payers in the lungs, contains liquids and gives, you will hear, when you shake the thorax, the fluctuation of the liquid; this is called by Hippocrates successions. sion, and since his time, has been known as Hippocratic succession. You may imitate this phenomenon by shaking a decanter containing a small quantity of liquid."pp. 82, 83, 84.

The following paragraphs relate to the abnormal resonance of the voice through the

parietes of the chest.

"The resonance of the voice is very distinct in the regions where the bronchi are superficial, but less so in those regions which correspond to laminæ of vesicles, on account of the numerous divisions experienced by the undulations of sound in arriving at the extreme ramifications of the bronchi.

"I. Hence, if the cavities of the vesicles be destroyed by any cause whatever, the voice will resound in the bronchi corresponding to the obliterated vesicles, and that in proportion to the greater or less extent of the obliteration. This abnormal resonance of the voice through the parietes of the chest, is called voix bronchique or bronchophonie. The impenetrability of the cavities of the vesicles, whether it result from the presence of tubercles, or from the concretion of the sero-sanguineous matter secreted by the parietes of the vesicles in the second stage of pneumonia, will therefore occasion this phenomenon.

"2. The same phenomenon is observable when the impenetrability of the vesicles is produced by an effusion in the cavity of the plcura. But if in this case the liquid be in too small a quantity to compress entirely the lamina of vesicles, and only causes a closer application of the pleurs to the parietes of the vesicles, so as to form therewith a mambrane more or less tense, applied to the extremities of the respiratory passages, the resonance of the voice will, in this case, offer a very remarkable character. It is a broken interrupted sound, like the sound of a person who stutters. It he

"According to certain

wals the case in plantal dilatation of a broad-chus, or in an exceptation of the lungs, con-sequent upon tablercles, the resonance of the voice in those parts is such, that the pa-tient seems to talk in the ear of the examiner, especially if the latter amountate with the stethoscope. This is pectorilogue, which is complete when the cavern is superficial, and adheres by its sides to the costal pleura, and when its angles are indurated; but it will be more diffuse, and may be heard over several different points of the chest, when it indicates a considerable dilatation of the bronchi. The hand applied over the arietes of the thorax during bronchophonic feels the parietal vibrations as in a normal condition. This phenomenon is no longer met with when the lungs are separated from the thoracic parietes by a certain quantity of liquid.'

The division of the volume which is devoted to the organ concerned in the circulation of the blood, is amongst the best in the work; it contains much original information, communicated with great perspiculty; but we shall quote no more, lest, without sufficient justification, we lay ourselves open to the charge, after treating the literary product in our critical alembic, of leaving only the caput mortuum for the benefit of the author.

The second part of the book is appropriated to the mode of applying auscultation principles to the diagnosis of particular diseases, and these are arranged into affections of the abdomen and pelvis, of the organs of respiration, and of the organs of circulation. Upon the whole, we can, in strict justice. recommend this "compendium" as a faithful and intelligent guide to all those who are desirous of learning the art of diagnosis by auscultation.

The Cyclepadia of Anatomy and Physiology Edited by R. B. Tonn, M.B. London: Sherwood.

THE publishers have now issued a sufficient portion of this work to enable us to form a better estimate of its claims to support, then when it last received a notice at ands. Parts 1, 2, 3, and 4, are before think that they afford materials perrect general view of the the undertaking. On ex-

omission: but as the arrangement of tonics is alphabetical, the deficiencies may be rectified in the future Parts, and we consider it probable that the Cyclopedia of Anatomy will ultimately supply an acknowledged histus in the literature of Great Britain.

The articles which have already appeared are for the most part well treated,-the natural result of a good selection of authors, in the list of whom, indeed, are the names of very many gentlemen of whom we may say, without any incautious respect for the authority of mere fame, that their engagement on the work affords a pledge that it will contain a large number of very excellent encyclopedic essays. The announcement of some of the "minora sidera" certainly excited a smile, and some surprise, perhaps. Their light, however, though simply twinkling, and not brilliant, may yet prove useful. As the Scotch say, "Many mickels make a muckle."

The nature and variety of the subjects embraced in the plan of the Cyclopædia are well known through the advertisements. The plan combines Physiology and Anatomy (Human and Comparative), with the essentials of Animal Chemistry.

With regard to the details of such a work, it is not in our power to give any useful account of them here. In speaking of the execution of the articles, we may particularly allude, for their excellence, to those on "Absorption," "Age," "Arachuida," "Aves." " Blood." Let us, however, take the opportunity of suggesting, that, as the work will necessarily be an expensive one. it is incumbent on the Editor to interpose his authority for the prevention of every circumstance that is likely to enhance its price without increasing its value. It should be the peremptory duty of the conductor to revise all the articles, with a view to repress diffuseness of style and redundancy of quotation. The exercise of a capacity to review the facts is not sufficient. The labours of literature, in a redacteur, comprise something more. The connection, also, which exists between the subjects of Zoology and Comparative Anatomy should not be broken, but to decide upon its extent the judgment and official powers of the Editor should be called into requisition, or the evil we have menhave schooled for explanationed may become a just source of comtioned may become a just source of e good, and afford most material sastistance in also of many intrinse per joyeve the author's pulsars

In the desertment of Comparative Anatomy Dr. Town possesses the assistance of the science-Professor GRANT and Mr. Owner, and every fresh record of the exertions of these able and learned philosophers adds to the gratification we derive from baving been the hamble means of blending this branch of stady in the department of medical education in England. Comparative Austoney was known to but few as an important division of medical learning until the brilliant course of Professor GRANT obtained universal diffusion in the profession in the pages of Tun LANCEY. The impression of its value and interest is now continually being testified by the writers, and in the schools devoted to our art. Dr. GRANT's "Lectures" constituted almost the only comprehensive and accessihis source of information on this subject in the English language. Now the parent has a numerous progeny. The "lectures" of Dr. GRANT, however, will for years stand unique for arrangement and details. But comparative Anatomy has now many labourers in the field, whose fruit is engerly sought, and duly devoured.

Compandium of the Ligaments (illustrated by Woodcuts), and the various Cartilages, Bynovial Membranes, Bursa Mucora, and Bones of the Joints; the Dislocations, Fractures, Physiology, and Pathology. By A. M'NAB, M.R.C.S., London : Benshaw. 1835.

Two work is a synopsis of the principal facts relating to the anatomy, physiology, and pathology of the joints. The author remarks that the study of medicine has been facilitated by condensing the writings of good authors, thus affording to all, the means of learning their contents at a cheap rate. The fibrons seructures especially, which are in immediate connection with the joints, are in general described in voluminous works, d these descriptions are dispersed through different chapters. Mr. M'Nab does not profess to present us with any thing novel, but he has collected the facts with industry, and arranged their with judgment.

Respecting the wardcuts, the less that is said of their execution the better. They How then con the

other respects the volume will prove morful details are faithto the dissense, because it two chief inhousers in that interesting ful. To the established presentations, too, it may serve as a useful " farmer."

THE LANCET.

84

London, Saturday, January 9, 1836.

No apology can be necessary for resuming, after a very brief interval of time, the question of founding a national University in this metropolis. We must regret appearing to be tedious on this or on any other subject, but we must hope that the objects which it is sought to accomplish by establishing the new institution, are of so important a character, and must, in their resulta, be attended with so many mighty consequences to the country, that too clear a view of the whole of the circumstances involved in the consideration of the proposed scheme, cannot be taken in the present early stage of the inquiry. If the members of the Government proceed with any degree of precipilately in this matter, they will erect a monument to perpetuate their own folly. In giving the executive Government credit for the best intentions towards the objects of science and the interests of the country. we cannot refrain from reminding them that something more than mere evidence of purity of motives is required in founding a great national institution, which is to be devoted to the culture of the powers of the human mind.

In contemplating the objects for which the University is to be called into an the principle on which it should. and governed, is not less as intellect of the philauthe sopher, then is the sun. senses of the andest.

the state of the

nervenier the on recognised schools, or institutions. The ratification, by moral CHARTER, of so monstrous a proposal, would andoubtedly tend to bring the Ministers of the Crown into contempt, because it would evidently have a tendency to make them appear as the abottors of monopolies, or of signalizing them as persons of too contracted an intellect to frame a scheme of University Government which should be national in its principles, and national in all its arrangements and functions. There is one sign which ought to warn them of the dangerous ground on which they now stand. We allude, necessarity, to the approval of the scheme by nearly the whole tribe of medical corruptionists and monopolists. Why have those persons given to it their sanction? Because they are well aware that if the University be founded strictly on the plan of the CHANCELLOR of the Excusquen, that the result will be a failure. These persons have sufficient cunning to know that if an University be not rich in its endowments, it cannot receive general support upon any other ground than on the solidity and extent of its reputation. In the instance before us there are NO ENDOWMENTS, and, unless appuration be first secured, if is not likely that any endowment will oppositly exist in the new University. Upon these views the calculations of the entire gang of corruptionists and monopolists are founded. In the infancy, at the sary entect, of the institution, unless the University take a high, an elevated position, in the opinion of the enlightened portion of the public, the candidates for the degrees will scarcely outsumber the memthe examining council. And we ask, That can be the extent of its aurusebume be only oriculated to and syour, to the odious of ""recognising" this been so long

position be sanctioned, or even tolerated, of old medical conscirutions? This question resion of that principle, to should be answered, deliberately answered, the functions of houndaries of two or three by the Ministers of the Crown, before they proceed with their project one step ferther. We repeat, that precipitancy on this occasion, will plunge them into an occasi of troubles and difficulties. How often does it happen that in discussing the details of a measure of referm, the principles which called that measure into existence, are wither wholly misrepresented, or are passed over in silence by the disputants. Who can have forgotten the reasons which were publicly proclaimed for founding University Callegs, viz., that the youth of the motropolis might enjoy the benefit of an University education; and, secondly, the establishment of an institution in which University henours might be acquired by all persons, without reference to religious creeds and distinctions? The objects, therefore, and the means of securing them, were resolvable into one general principle, of a wholly naliere we observed that tional character. the vile and sordid practice of "recognising" particular establishments, to the exclusion of others, in awarding University honours, was scorned and repudiated, not indeed so much in words as by the very principle which conferred upon the new institution life, energy, and strength. The partialities of Oxford and Cambridge had long been denounced, because it was generally falt, by the more enlightened portion of the empire, that in those Universities, bigotry and religious prejudice had often but too much share in making candidates successful in their applications for degrees. The "recognition" in those institutions was not of a favourable description, maless there was a " subscription " to cortain andcles of belief,-an exaction of too insolvent and odious a character to be any longer endured by the members of a well-informed community. What then, are we to have in the new University of London ? Not. indeed, the demand of a signature to "curtain articles of belief,"-not a "minimurles

most butsful. Both demands are equally the buildings, and the general arrangements changions to the cultivation and the free of which appear to be capable of accomprogress of the human intellect. The stig- plishing the objects which are specified in the brand, of partiality, is manifest in the University curriculum, then it must be hoth cases, and although some excess might at once confessed that the new institution is he found in the instances of Oxford and not dedicated to the knowledge, but to the Combridge, for an adherence to a line of wealth of the nation. It would be another circumstances of the period when it was of oosn. Have the members of the medifirst suggested and set in motion, yet there cal profession forgotten the anathemas which can be no just ground whatever, while esta- have for so many years been fulminated blishing an University in this empire, in the against the President, the Censors, and the minuterath century, for rendering wealth, or, Fellows, of the London College of Physimore correctly speaking, the non-aristence of cians? And what has been the offence wealth, an obstacle, as gross and obstructive with reference to the procuration of Univerity honours, as was that of religious intolerance in the fifteenth century. We again ask, "What is it that the Ministers design to reward?" and in answering the question we trust that the real sentiments of the individuals will not be disguised by a liberal display of plausible words. If the portals of the new University be thrown open to candidies, without any regard to the places of their education, and no other introduction to the examination be required than is to he found in the testimonials of an unimpeachable moral character, the University of London would at once far excel, in reputation and utility, every other University in Europe. But if Ministers, in setting this metional institution in motion, require that it shall be reached only through two or three "recognised" TOLL GATES, representing only new colleges, or old corporation schools, it will but exist, as we have already said, as an unhappy evidence of the absence of angacity and foresight in the minds of its founders. There can be no mistake as to the result. The gift of prowherey is not required in this instance to the country, institu

ticular cross,—but the eri- foretell the state of the festire, for in the of a miles pitter of money. In the one very arrangements which have streamy been case the Dangon or Ricorn's is to be pro- suggested, there are seen the elements of tiated; in the other, the DEMON of disunion and decay. If the "recognitions" of the senate of the new University are to be grealy say which Dunson is the confined to particular schools,—the funds, inclubich may have been justified by the costly and pernicious sacrifice to the nower committed by those parties, - the one offence which has obtained for them either the hatred or the contempt of every liberalminded physician or surgeon in this kingdom? It was simply this,-that they refused to examine any condidates for the Fellowship of their College who had not obtained degrees in medicine at Oxford or Cambridge. Really this is a striking fact. 'It was owing to the existence of this disgraceful partiality that the recently-established University College received the warm and generous support of so many enlightened medical practitioners. The Fellows of the disgraced College of Physicians have contended, and still contend, that the charter has ever empowered them to make exceptions in favour of graduates of our two ancient Universities. What, then, are we, in founding a new institution, to create other exceptions, which must prove as obnoxious and pernicions as those which are already in existence? The Fellows of the College of Physics their conduct have utterie only the respectability, the their institution. ously and invited

Insolently and lamphtily to every condidate | juga all distinctions, partialities, and except who had failed to supend-uselessly expend tions, with ref hundreds of pounds starling at Oxford or Cambridge, that College would at this moment have been taking the lead of every other medical institution in Europe, in all matters relating to the interesting and important science of medicine. From acting, however, in the odious system of restriction, partiality, and monopoly, the College of Physicians carries with it not the slightest degree of influence with any ten individuals belonging to the least-informed members of the profession. Every man, therefore, who prefers honesty of purpose and comprehensiveness of principle rather than intrigue, monopoly, and narrow-mindedness, will learn with a sense of loathing, if not with a feeling of horror, that our present liberal Ministry have, even for a moment, entertained the idea of framing a charter, in which, under the authority of the sign-manual of the King, there should be constructed, in the year 1836, some new arrangements for carryon, with increased vigour, the old exploded system of favouritism, recognition, and monopoly.

" But," it will be remarked, "if distinc-" tions be made in favour of University Cul-" lege, King's College, and two or three other " catablishments, will not the privileges thus "conferred, prove of great advantage by " raising the standard of education in those " institutions?"

If this observation be well founded, are the utterers of it to limit the general tendency of its application? If the standard of education is to be raised in two establishments, why not in six, and if in six, why not in all that the country can produce? This would be a real national benefit. Then, indeed, a stimulus would be given to the a of literature and a knowledge which the existing monopolies ngossible to destroy, or even the charter, there-Ministry to ab-Water tar Salt . in

rence to Universities, or -many valuable years of his life, and many scholastic establishments, of whatever description. At the same time we desire of them to insist that the senate of the new University shall require from the candidates for the degrees, such proofs, furnished craffy and in writing, of an extent of qualification which shall entitle the candidate to receive the honour which he is auxious to elitain,the University distinction which they are empowered to award. In such a scheme no sanction will be given to " curricula" for "the schools." The examination alone will, in such cases, necessarily determine. in the best and most effective manner, those subjects of study which ought to the aresented by the professors to the attention of the student. The object to be attained, will be the natural and rational stimular of the pupil, and the subjects to be included in the public examination before the senate, will necessarily determine what shall be the qualifications, and what shall be the duties, of the professors and lecturers in the chief scholastic establishments of the empire:

> Under some such scheme as this, the new institution would rise at once into beauty and grandeur, as an offering rendered to THE GENIUS OF THE NATION. If, however, it is to be made a thing of " shreds and patches," of jumbles and exceptions, distinctions and partialities, it will be called into action under the influence of an unworthy spirit, and as such, it will remain an object of perpetual reproach to its well-intentioned but deluded founders.

> Since the foregoing article was written, a report has reached us which is in no repect curious, except for the malignity of the falsehood on which it is based.

> It is stated that the CHANCELLOR of the Excusouss, after having received deputations from those two filthy dens of menopoly and corruption, the College of Physicians, and the College of Surgeons, has referred the arrangement of the Valversity The talk of participation

to the talk or bearing and it goods

constion, so far as the medical department foolish, Separas It is is consorted, to Dr. Characters, Dr. Hot- mischievers, to require any person who is LAND, and Sir RENJAMIN BRODIE. This is not thus qualified, to execute the important the report. This is the felsehood. If Mr. functions mikich Coroners, at the great Sixture Ries could have given but why majority of inquests, are necessarily called should we say if! The thing is impossible. Still, we say, if Mr. Ricz have listened in silence to such a proposition, he ought not to escape without being reminded of what was said by himself in the House of Commons, when the Lords examined the Town Clarks of the old Municipal Corporations, as to what had been the result of the old eye-They obvious reasons, will resort to every species of stratagem, and every manosuvre, in order to delay the settlement of the University question, is sufficiently plain to the heart discerning individual, but that Mr. Spains Rice or his colleagues will fail into any one of the many snares which are set for him and them, by the wily enemies of a liberal system of medical education and national improvement, is a minfortune which, we believe, cannot occur. It may be well, however, to tell the CHANCELLOR of the Excureves, that no two corporations in the United Kingdom of Great Britain, are so thoroughly, so heartily, detested by, probibly, at least, fifteen thousand medical practitioners, as are the London College of Phynicians and the London College of Surgeons. If, therefore, any liberal-minded legislator turn his attention towards these established ments, it must be in the hope of avoiding every thing that is sanctioned or practised therein to imitate, nothing.

WE have observed with much satisfaction. that the new Town Councils have in several instances been addressed by medical genflemen, who have been solicitize the appointment of Coroner for the borough. If this office is to be snything but a nullity, it must be alled by a gentleman who has been particularly for a per made signal to the discharge of its duties by for so long a. a medical education. It is worse than dolenge,

upon to discharge.

THE concours for the chair of clinical surgery, now vacant in the Faculty of Medicine of Paris, commenced on the 2nd of this month. The candidates were, MM. SAN-SON, GUERDON, BERARD jun., LEPELLE-TIER, and BLANDIN, who all competed last year in the concours, which we reported so fully at the time. In addition to these gentlemen, we find only three new candidates, MM. JOHERT DE LAMBALLE, SEDILLOT, and LAUGIER. M. LISTRANC, convinced of the impossibility of being received amongst a body to which he has always been hostile, has retired from the field; although, curiously enough, he has since been sent as one of the four judges, by the Academy of Medicine.

THE concours, in Paris, for the anatomical chair, will not open before the 14th of April next.

Some months ago, Moses-Monte-Sanc-To was elected a corresponding member of the Royal Academy of Medicina, Paris. At the last sitting of the Academy, M. GUENEAU announced that M. Monte-Sancro was unable to avail himself of the honour conferred upon him, as the Austrian Government refused their authorization to accept Prench degrees.

INTERCEPTED LETTER

"DEAR DR. MACHICHARL,-You must spologize to my numerous friends who have been making anxious inquiries about me and all my concerns, and you must explain to all of them how impossible it is for me to resume at once my many arduous functions diately on my arrival in this labyris can scarcely imagine the effect a change of subjects for con of objects around me, and I to get into habits

life. Businarastu, ithose gigantic intellect of two to be the whole business of she affabled him to combinate mankind in all its relations, made in observation, when on his flight from litude, which has been often brought to my recallection, and which is particularly applicable to myielf at the present moment. Narouzou, on his strival at Wilns, had taken up his residence for the night at the house of the mayor of that city, and taken up his residence for the night at the house of the mayor of that city, and which I his while a line which I him the sine which I had the s and whilst walking about the room, in sullen meditation, began talking to himself, -for the Emperor was accustomed to put questions to himself and then reply to them. the midst of the soliloguy he was heard to exclaim, "Good Heaven! how strange! There is but one step from the sublime to the ridiculous!" Now, far be it from me to compare myself, in many respects, with the great Navolzon, but I cannot help per-ceiving the accuracy of his observation to be applicable to myself, under present circumutances. To tell you the truth, my good friend, my position as a country squire, living richly in my own domains, never being visible beyond my own territory, unless in a splendid carriage, with four prancing horses, -this sublime state, contrasted with my avocations here, makes me feel that I am, at this moment, assuredly in a ridiculous plight, being every instant liable to be called to Kensington, or some other such place, to fect the pulse of a princess, and to look at her tongue, and then, perhaps, directly after, being obliged to address myself to her French maid, Mademoiselle Numertle, eyes is bonte, ma chere amie, de montrer le pot de chambre." This, however, as you know, is only one of the many disagreeable things that the pure physician must submit to, in order to impress on his patient a sense of the superior knowledge which he possesses of all internal diseases.

"While alluding to NAPOLEON, there is a point to which I cannot but refer on this occasion, as one wherein I possess an acknowledged superiority over the late Emperor; I mean in my classical learning. His biographers tell us, that he was extremely ignorant of the dead languages, and that when he was at Brienne, receiving his proliminary education, such was his backwardness in acquiring a knowledge of Greek and Latin, that he procured with difficulty admission into the Roble Politecksigns. In future life he often alluded to this, and used to quote a passage from Locas on Education, wherein that profound philosopher has, incautiously for the inte-rustrum our Universities, used these words. I gonsider (says Locks) what ado is a little Greek and Latin, how

FORESCHOOL SON STREET, STREET,

tion. How size is it possible that a cl

"You must not suppose, my dear friend, that the time which I have spent in the country has been altogether lost, or that it has been uselessly employed. It is under circumstances of rural retirement, that I have experienced the extended hencilta of that strict moral and virtuous course of education which I received at Oxford, and that I have been able also to reflect on the immoral and licentious habits so emerally practised in my time by the studiests of the University of Edinbergh. The idea thank felicity, observes an enlightened with a so congenial with the human mind, that cannot wonder to find it cherished at all the hurry and dissipation of public life, especially if we consider that such a life is often attended with labour and sorrow, with often attended with labour and manage weariness and disappointment. When we weariness and disappointment. look abroad into the world, we see fixed down to his desk, or stationed behind his counter, and from morning to night busily engaged in arranging his accounts, or dealing out his commodities, with scarcely sufficient intervals for the refreshment or support of nature. We see another, sepiring after some place of honour or of profit, wrapt with suspense in the pursuit, frequently baffled in his object, and if at length successful, dissatisfied with the acquirsition. While a third, whose situation may appear more enviable, who,-alike exempt from the toils of the city and the ambilion of the court, has no other concern than, to enjoy the amusements and pleasures of li -is often found a miserable prey to chagrin, from the caprices and jealousies which are sure to infect the brightest circles of gayety and fashion. In all these cases the mind naturally looks forward to the country, to the independence of some rural retreat, the peaceful labours of husbandry, the diver-sions of the field, or the scenery of nature, for purer sources of anjoyment. How true is the language of Thouson :-

Rottrement, reral quiet, trionitable, books, Ease and atternate labous, useful life, Progressive virtue, and approving Meaven!

" Besides participating in the amusements and recreations of a country squire, I ha occasionally employed myself in readi those classic authors from whom I deriv such delight when at college, - a source of the spent in it, and what a noise incidentual pleasure which is one our approximation that the parents of the shooting with the only indiced, except he who has partaken of it. I have not troubled my head much, as you may have not the partaken of it. I have not work on the only indiced, excepting Mr. Wanner's work on blood-letting, I have not obtained much pleasure from anglother Riemary-gardension, that we shall share the property of the property o much more comprehensive manner than he could have done had he not possessed a thorough knowledge of physic. It is there where general practitioners have advantages over the perer grades. Indeed, I am free to confees, and it matters not for me, at my time of life, to let it be generally known, hilation would be disastrous to him, had be that Limes often had eccasion deeply to is not something else to look to. I rejoice to entany ignorance of surgery, and I shall take near favourable opportunity of pointing out to the sounger fellows how seriously their worldly interests are affected by their ignorance of that art, and the bad habit most of them have of affecting to sneer at everything like a knowledge of those dis-cases which require surgical aid.

"New that I am once more amongst my professional brethren, it behoves me to derote all the energies of my mind to promote the good of our great cause, and as I can report but few patients at this season of he year, I shall not fail to pender well on College matters. The granting of licenses will have no effect. CHAMBERS is too lofty must not be delayed a day, and you may and rough, and wants that susviler in mode order Dr. Asuwall to come first before us, on trial. The very idea of these German tors makes me smile. But we must treat the matter gravely. So long accustomed as we had been to license the Scotch no one but Madame V,, whose case, I am dubs, I never thought anything about them, and certainly we had some first-rate men amongst them, but to have to do with a squad of Dutchmen is really quite ridicues; and if it were anyhow possible to keep the machine in Pall-Mall going without granting their admission, we should not run the risk of placing within our enemy's reach so powerful an engine of satire. I always remember, with regret, the laugh against us for inducing the good ARCHRISHOP to give CHARLES CLARER & degree. But as things are, we must fearlessly adopt extreme mea-

"Next to the 'ways and means,' as my dear friend Sir ROBERT PREL calls them, comes the Metropolitan University. Here we must strain every nerve. As I told you higher. I have never been committed by any manufact of the Government, directly or indirectly, as which, however, I am not sured, considering that I think and act so specially as they must know how cleverly generally as they must know how cleverly generated the Peel-Wellington Adminitration from making any changes in Pali-with vention, with true facilities of the many changes in Pali-with vention, with the limit arold being awareped, and I do anger Walker, in the limit arold being awareped, and I do anger with the limit arold being awareped, and I do anger with the limit arold being awareped, and I do anger with the limit arold being awareped, and I do anger with the limit arold being awareped.

will throw his friends at Lincoln's-Inn overboard, and accept office. He must be watched closely. Neither would I trust Sir ASTLEY, notwithstanding all he says, if the cortificate-system he wholly exploded. He flourished and lived under it, and its annilearn from Lady BRODIE, that Sir Aurt.EY has taken a serious furn latterly. It is such a revelution, that I can only hope it is true. ado not expect that we shall get much good from the negotiations of HOLLAND and CHAMBERS. HOLLAND having endeavoured, after being a Whig all his life, to cut a favour with the Tories, when every rational man must have believed that they would hold office for ever, and having, now that the Whigs are in power once more, again become a Whig, I have no faith in him. His opinions will not be hearkened to; even the sweetness and simplicity of his manners which gives me so much influence over the human mind. Let Turren, Nussey, Tra-GART, PULLER, and all the top men in that line, know of my arrival. I have yet seen happy to say, I have hit exactly. I discovered that she has an affection of the heart, and I told her that the system of treatment which I would adopt was mild, and unattended with pain or danger, and that a ---- might also be required to perform a redical cure. Write a paragraph for the Sunday Times, announcing my having been consulted on this interesting case, and believe me always yours,

"Curson-street, Dec. 1835,"

ADMINISTRATION OF CREOSOTE.

AND SOME OTHER MEDICINES, NOT ALWAYS REMEDIALLY EUCCHONUL

To the Editor of THE L.

lately-sublished clinique lacture delivered by DR Effiction. The dishe recorded by Dr. Effictions are dive, in Dr. Walker admits, and the case now inshed by Dr. W. is but one case; I think, therefore, that he could to have carried his observations fact By reference to ether clinical lactures of Dr. Ellictson, Dr. Walker would have discovered that Dr. E. has had cases in which crecopate has failed to relieve gastrodynia and vomiting, as well as Dr. Walker, and that Dr. Elliotson, therefore, does not anticipate invariable success in the use of that medicine. There are many circumstances which materially modify the action of medicines, which must be taken into account. Thus, there was a case in our hospital last week, in which prussic acid was given to allay gastrodynia and vomiting; but each dose of the medicine increased the vomiting; but, on looking to the mode of exhibition, there was discovered the cause. The patient was taking the hydrocyanic acid in peppermint water, and that made him vomit. Peppermint is known to have this effect with many people. On substituting cinnamon water for aq. menth, pip., the medicine immediately had the desired effect, and she was discharged cured in a few days. Now Dr. Walker administered the creesote in his case in mucilage, and how do we know but that it was the mucilage, and not the creosote, that caused the vomiting? Nay, there is now a patient in our hospital who could not retain on his stomach a dose of a mucilaginous mixture which she was taking for a cough, although she did not vomit on taking other things. Again, ascribe the effects produced to the creosote, and even idiosyncrasy might play its part. There are those on whom medicines of various sorts have very unusual effects. Thus, a patient in our hospital last month, had her gume become tender whenever she left off morcury, and they got well again as soon as the resumed it.

We can only account for such anomalous cases by regarding them as the result of idiosyncrasy, so that by that same cause it will and does happen, that with one patient creosots will answer best, with another opium, with a third prussic acid, and so on. Accordingly Dr. Elliotson does not employ creosote riminately, as might be inferred from Dr. W.'s letter, or from the parusal probably of one clinical lecture, but at this moment he is giving to one patient prussic acid, to another cruosote, and to another stramonium, to allay pain in the stomach and vomiting. In the case in which he is giving stramonium; are the succeeded for a while, and afterpnaveiling, and now stramorelief. In another case prussic gether to rollers vomiting, Anti-Ame of crecente

creaming and appropriate many cases it has proved beneficial after the fallaxe of everything else; but then it sums be administrated in different ways, according to circumstances; and as to Dr. Elifesten's "plan" being "two deeps in muclings and water every six hours," that is not at all the enio, for he mould given it in plain water, and sometimes is obliged to impresse the deep do twenty drops, "or more, said that not only every six, but every four, or every those hours.

I would not have written in angu-Dr. Walker's letter had he not com an error which is likely to do mad chief, and is too often repeated, -via of drawing general conclusions from it facts. In another medical period week ago, Dr. Ellistson is censured. indiscriminate use of iodine, as the employed it as a paracen—as an unityer remedy for all diseases, which no unit w knows anything of that gentleman's prec-tice can for a moment assert. It may not be amiss to state here, what is not generally known; viz., that if cressete be not carefully parified, it contains on to substance, which passes over with it in the distillation. This fact was unknown to the chemist who first prepared creases; and, consequently, much of the creases which he at first sent into the market, actually contained a most powerfully ematic substance. Hence, perhaps, in part, have arisen the discrepancies with regard to its virtues as an anti-emetic. I am, Sir, yours pespectfully,

A STUDENT AT THE NORTH-

Dec. 22, 1835,

e.º We object to opening our columns to the controversy which would arise from the publication of some passages and remarks which we have omitted—but without at all interfering with his legitimate object.—from the letter of our correspondent. We have endeavoured to limit his statements to facts which may here usefully obtain insertion.

MEDICAL MAGNETISM.

To the Editor of Tun LANCOT.

Stn.—The candid importality with which you listen to noth sides of any question that may be brought before you, assures in that you will give a place in your journal to the lellowing shuple maximum of faction.

Mr. Davidson says, in his latter immetal in has work's Larcar, that he regress having been mentioned in consistints with the subject of induced magnetism. How this can be a cause of regres with Mr. D. Lain at a less to consistery he was not facused have

To make the strong, Mr. D. brings forward formalesses manner. He says, Drs. Peraday and Ritchie dony any curative pro-perty in the magnet! However valuable he authority of those names is every other papers may be, it is inadmissible in this, as respect may be, 13 19 Institute pure in this, as based upon theory only. One figt certainly is worth all the shearies in the world. Notther of these gentlemen will hold a thing impossible because he does not see how it is effected. This would be unphilosophical indeed! Mr. D. further states, that there is rathing new in my method. Now Mr. D. ought to have stated at the same time, that he is incompetent to give an opinion, bething of the magnet. The gentlemen on whose authority Mr. D. seems to make this statement, are neither of them fully sequainted with my views, and they certainly would not wish to condemn any one's opi-nions before hearing them. And though it is with the utmost reluctance that I make use expressed by the parties themselves. Dr. Ritchie said, before the Westminster Medical As to myself, I do swert, that in magnetiz-ing, the poles produce their like and not their opposites; all magnetizing is but a continuation of the like pole, and quite the same whether by contact or induction. I finally maintain; that like, and not opposite, poles assist each other. By simply following out these views, I have succeeded to obtain results, both in the construction and application of the magnet, not achieved before. My magnets are more powerful than others, because they are constructed on what I conceive the right principles.
It will be fresh in the recollection of every

member of the Westminster Medical Society then present, that it was with considerable reluctance I accepted Mr. Hale Thomson's kind offer to experiment on amaurotic pa-tions in the Westminster Ophthalmic Hospilal. Lany with reluctance, because I foresaw the objections that could be raised against experiments on the eye. It is morewell known that many cases of amau-

自动有有效的

the subject, but came forward of his own companied by glancaging the other became free will, to make some statements to defend amaurotic after un distinguis for and the amazrotic after an manufacture and the third had been operated again startioning for cataract, when a piece of the capsule remained in the posterior chamber.

Mr. Gutterle, moreover, has kindly expressed himself several times, that none of the cases could be considered appropriate. Now in the one case I excepted, the patient professes to have received considerable benefit; the same, though in a less degree, was the case with two of the others. In most cases where the magnet is used, it is applied over the clothing and does not come in contact with the body, when, of course, no objections as to effects produced by the metal only can exist. And now a few words with regard to what Mr. D. calls an inquiry after truth. In the first place, I think it would have been fair to have stated that I at once admitted that cold would produce lachrymation, and that I applied the cold iron, fally expecting it would do so. But I say that iron will not produce that great mobility of the iris, which follows the application of the magnet. There can be little doubt but a piece of cold iron will produce of names, I believe that I owe it to myself doubt but a piece of cold iron will produce to state, that Mr. Faraday pronounced my similar effects on the eyes of four or five views, as far as he was aware of them, to be healthy individuals, but not precisely the new on some points, and worthy of investi- same, as Mr. D. says, for on some it would gation. Singular it seems to hear opinions | not produce any perceivable effect whatever; quoted, which differ essentially from those; others would feel heat, and some both cold and heat. But what has this do with the magnet? Mr. Thomson not remembering Society, that in magnetizing, both poles were that cold iron produces lachrymation, very produced simultaneously. Now this is cernaturally considered it as one of the effects
tainly different from what is said by Mr. D. of the magnet, and he certainly would have taken an opportunity to correct his mistake, had such occurred. To me Mr. D.'s inquiry after truth, seems a wish to tell the public what great authorities are opposed to the magnet being used as a remedy, and to make them aware that he is of the same opinion. I remain, Sir, your very obedient servant,

CHARLES SCHMIDT. 137, Regent-street, Jan. 5, 1836.

TWO CARES OF

GLANDERS IN THE HUMAN BRING. CURED BY CREOSOTE.

Related by Mr. J. P. CHERTHAM, London, in. the Veterinarian, Jan. 1885.

The susceptibility of the human frame contract those dire maladies deliber we well known that many cases of mass contract those dire mainting descriptions of the large partitions are made and the large partitions and the large partitions of the larg

A summary detail mentaining to the appropriate of the affected horse there was in increased scoretion of will exhibit the materix of the disease.

In the months of April last, I was requested to examine a bay horse declared to have a common cold, with secretion of pas from the mostrils, but which had continued during as inordinate time. A person who shall be nameless, forwarded some halls that were said to be infallible. The owner, in order to be assured that they were administered, gave them himself; but not being very expert in this occupation, he lost a part of the cuticle from the kauckle of the fore-finger.

The symptoms presented by the horse were, the glanderous discharge with the fettid effluvium; extensive ulceration of the pituitary membrane covering the masal septum; enlarged and indurated lymphatic glands, occupying nearly the whole space between the posterior maxillary bones, projecting beyond their margins, and displaying themselves even to the sight; and the cough short and difficult, indicating the thercular condition of the respiratory organs. His coat and outward appearance, however, presented an apparently healthy aspect.

My advice was to destroy him, being certain of his death, and likewise knowing the danger of propagating the disease to other horses, and to the persons who were in attendance. The owner was unwilling to sacrifice his favourite, and pressed me to give medicine, valuing neither time nor latour. In order to satisfy his mind, I ordered the blue draught (sulph. cupri) to be administered twice x-day.

In the course of a week after this, the owner informed me that the horse had amended. Considering this rather a strange anomaly, I forthwith visited the patient, and satisfied myself that, instead of amending, he was quite the reverse, for blood was interwoven with the discharge; the breathing was laborious and difficult, and, especially, it was accompanied by a very peculiar sound in the nasal passages. In a few weeks the proprietor told me that the horse had been sent to the knackers' yard, and at the same time I heard that he and his man were similarly diseased.

The smell and the discharge were of an identical character with those smitted by the horse; and on examination my opinion fully coincided with his. From the resemblance of the characteristic symptoms in both, a general description will andice. The coarse conjugatory to have notered the through an abrasion of the through the modium of a sore on the land, and in the coarse of the modium of a sore on the

Me Appen of time print to the appearance of the Money is an Eventy of the Appendix of the State of the State

when their presents from glandsmust seatter there was his hierapsed scentiline of mesons from the noise, which was attributed to mile catarrh, spill the character of the discharge, the blood intermingled with \$2, pain in the frontal sinuses and the cavities of the meson and short and interrupted along, roused them to a state of anxiety.

The pus with its gluey, slimy, glanderous appearance, itsisfied me as to their real state. I could discern no distinct alcers on the pituitary membrane; but from the statements given by the patients, I should incline to decide that they existed in the remote parts of the nose. The threat, on pressure, was rather painful, and the lymphatic glands were enlarged.

These patients having come so much mader my own observation, I shall give home account of the treatment of their respicative cases by Dr. Elliotson. The servants was admitted into the North-London Housial, and the master attended by Dr. Elliotson.

By injecting a solution of creecete in water up the nostrils thrice a day—by this simple means, and this alone—the servant was brought to a state of convalences in ten days, and the master in a little longer time. If the local application of the cree-sote had proved insufficient, it would have been administered internally. The strength of the injection was changed according to the stimulating effect produced. At first the cases admitted of two minims to the ounce of water, until the parts began to alter their morbid state.

These facts will add to the triumph of those speculative theorists who consider that glanders is a mere local affection. My purpose here is not to open the way for controversy on a disease that every pretander assures himself he possesses a specific for. The cases, however, are worthy of record: Perhaps they may lead to a course of experiments on the power of the especial control of the contro

[In a paper in the last volume of "The Transactions of the Royal Medical and Chirurgical Society," Dr. Elliotson refers to the above two cases. "I am anxious," says be, "to mention its effect (the effect of createte) in two cases of chreating plandarity affecting one coastel and the frontal ellions with pain, and a copions and tetid discharge, The disease in the two persons was clearly purpose doing myself the honour of laying the facts before the Society early near fluid, in the control of the control of the control of the control of the second of or meta-rith on instance like these in the human indicate, former cases having been acute glandaries in checonic fator. The seculous injection of a

weak solution of creceote up the nostrillyears, abandoned a practice which he had seasoned the whole of the symplicies after a very few weeks, and I hear the distincts are still well. I need not say that the discome has always hitherto proved fatal in the

With some exceptions, Jew and for I tween, and some of them of a very doubtful character, glanders "has always, hitherto, proved fatal to the horse." Should we at length and a care for this cyclecte, although only in its chromic form, the faterinary proion will be under deep obligation to Dr. Ellioteon. We shall wait with some impatience for this valuable document, and in the meantime, some zealous veterinarian will, we trust, put the power of creosote to the test in the cases of chronic glanders, and favour his brethren with the result. - Ed. V.

GUY'S MOSPITAL BEPORTS.

THE example set by Mr. F. South, an " interne" of St. Thomas's Hospital, Southwark, has found speedy imitators in two "externes" of Guy's Hospital, its neighbour; and we have before us, consequently, a thick pamphlet under the above name. The circumstances under which this production has originated, the anticipations of its projectors, and the prospects of the contemplated series, must form subjects for our pen on another occasion. At present we shall simply way, that so low is the ebb of literature at " Guy's," that the medical officers have actually been to Bath for an introduction to their work!

Dr. Bright "opens the ball." We have denced through one fandango with the old "lady, and below present our readers with a condensed account of her conversation while performing the labour. "If a man," said the dowager, " have, through ignorance, in early youth, or at any other time, whispered noft falsities in the ear of the public whom he hath courted, he should certainly repeal and amend his tale when he gets older and wiser. I once committed errors of this kind, and deluded those whose favour I sought. In a few years more I saw that I was wrong. I cught to have "confessed" at once; yet something held me back; bot now after the revolution of many more years, I am going to tell you my faults." tripping on, with tongue and feet, we obtained from our partner the astounding morning, by a dose of castor oil, a

previously recommended for its excellence to the profession, without ever hinting to them until this very day, that that practice war materially calculated to keep up the disease which he originally designed it to lessen. We condense the details, which are distributed through half-a-dozen pages of the "Reports"-into the following passages. The original article, with a case of "Simple fever, protracted by Irritation or the Bowels, and attended by Relapse," appears in the form of "Observations" or

TREATMENT OF FEVER.

THE physician should review from time to time his published opinions, that he may see how far experience bears out his former impressions. With this feeling I detail s case of simple fever protracted by irritation of the bowels. Eight years ago I stated my thoughts on the treatment of fever. Additional experience has induced me to make some important modifications, adopted from the practice of others.

In a great majority of the cases of fever treated, more particularly of those which are admitted into an hospisal, the period has passed when the febrile action could be cut short. It is established, and, as it must run its course, it is our task to conduct it through as safely as possible. No danger, then, so frequently presents, as that which results from irritation in the lining membrane of the alimentary canal, more particularly in portions of the ilium, the execum, and in the colon, generally with great derangement in the digestive functions. To obviate this state, I formerly said that the combination of the hydrargyrum c. creta the ipecacuanha, and the compound chalk powder, in different proportions, with the mildest nourishment, caused the symptoms regularly to retire. This practice has been followed by others with great satisfaction, but I now conceive that even this mild combination has, in many cases, kept up the irritation longer than would have been the case, had a more soothing practice been adopted: in point of fact I have not, for many years, had recourse to this combination, except for temporary purposes, scarcely ever now continuing its use in the way I once recommended.

As regarde purgatives in the stages of fever, I almost communication myself to small doses of the small doses of the small doses of the small doses. creft, varying from two grains to distand followed, in about four hours, or the most confession that Dr. Bright had, for many limited to two dradiess, seldom incress wordstaying in 1993 gir stoff butter than worth or since our tout that will in

half an orace, and hever exceeding six tonic: when where is administered, it should drachms, to which wary often add from be only by the ounce.

two to six drops of sections of opium.

I further observed, eight years ago, that as a part of the disphoretic plan in fever, the ipecacuanha wine assisted a free discharge by the skin: but, that in mining cases, harm rather than good is done by the use of saline remedies and disphoretics in any form, as they irritate the bowels. Forcibly impressed with the injurious effects of most of our disphoretic remedies, I have of late, in a very great degree, relinquished them; and have substituted a remedy, which I was first induced to try, from seeing its very favourable action in the hands of Dr. Addison; that is, the carbonate of sods, in doses of from ten to twelve or fifteen grains, three times s-day, in some mild aromatic infusion, as the infusion of mint; and this now generally supplies the place of all other saline combinations. It certainly irritates the bowels less than most other remedies given in fever, though it is occasionally necessary to guard even this with a drop or two of the tincture of opium. How the soda acts I am unable to say: but somemes, in spite of all our care, diarrhoea ureatens, and the stools assume the peculiar unhealthy appearance which belongs to this character of fever. To check them too suddenly would be wrong. In these cases, I find most excellent assistance in a clyster of a few ounces of grucl or starch, with a small quantity of the sirup of poppies, varying, according to circumstances, from a drachm to three drachins; and this repeated once or twice, or oftener, in the day, according to the urgency of the symptoms. For this remedy I am indebted to Dr. Robert Williams. I have, in most instances, found it decidedly preferable to the ordinary opiate clysters which I was accustomed sometimes to employ, and which will still be occasionally found indispensable. The advantage of the sirup of poppies over the tincture of opium seems to be, the greater mildness of its action. In that class and stage of fevers to which the present obser-vations refer, I should say - Keep the patient tranquil, shave the head, and apply a cooling embrocation. Let the only food be fresh barley-water, or toast-water; or if, occasionally, a little more support is required, arrow-root and mild animal broth. Give the soda regularly: regulate the evacuations with the hydrargyrum c. creti and the castor oil: if the bowels need restraint, use inpoppy sirup and starch: if the starch is the starch is the ten-

The case to which these observations refer was an instance of febrile irritation, kept up to a great length of time, and, when co valencence had apparently beauestablish a little neglect of diet, with animal food-to a relapse, which threatened in fatal res In the cases of the disease, a few grain calomel, well guarded in their operati-will occasionally be found most decides useful, but I am quite convinced that gra-mischlef results, in all stages of the d ease, from the incantions use of this reme

NORTH-LONDON HOSPITAL

REMOVAL OF CALCULY FROM THE URRTHRA.—Mr. Liston, on the 1st instant, removed three small calculi from the urethra of a little boy, aged four years and a half. The patient had suffered for some time with symptoms of stone in the bladder, and he had been sounded at one of the London hospitals, but no calculus was detected. On his admission here, the sound being introduced, it was found that the wrethra was partially obstructed by calculi, about half an inch from the orifice. The grating of the instrument over these bodies rendered the diagnosis, as to the presence of any stones in the bladder, very obscure. Mr. L. removed three small stones of a sub-triangular shape, and of about the size of half a common nut, in the following manner. He introduced a sharp-pointed curved bistoury through the meatus, and widened the passage on each side. The stones were then easily accoped out. Mr. Liston preferred this mode of procedure in this case, to making an incision from beneath the urethra. Had the stones been situated further down the pas-sage, he would, he said, have pushed them behind the scrotum, and cut down upon them through the perineum.

THE TAXIS IN HERNIA. - In a clinical lecture the other day, Mr. Liston remarked that he believed that operations for strangulated hernia were resorted to far more frequently than was really necessary. He believed that almost all cases might be relieved by the steady and persevering application of the taxis, particularly if resorted to within twelve hours in inguinal hernia, and six or eight hours in crural, after the strangulation has occurred. The warmbath and bleeding might be advantageously evaployed in many cases. Of course in of the hladder fragmently by placing the use of the taxis, it required in the operation hand over the layer, part of the abdoman.

If the strongth fall, the influence expensions with a few grains of the subcarbonate past with a few grains of the subcarbonate past and a few grains o

with much loss danger to the re was loss fear of acute peri-mention coming on, and, of hance of recovery. It must retood, however, when recommendthe steady and persevering employment the taxis, that he did not sanction any eart or violence, nor the carrying the appli-cation beyond reasonable limits. The first indication in this operation was the reduction of the bulk of the tumour, which was cted by squeezing the air contained in the extruded bowels into that within the challen. The pressure was to be kept steadily up for fifteen or twenty minutes, and the contents, if possible, gradually pushed back late the abdomen.

CARE OF GONORNEGAL DISCHARGE, ACCOM-PARIED WITH CONDYLONA AND CONDY-LOMATOUS TECHNATION.

LUCY CARYER, meat. 17, was admitted on the 13th of March, 1835, under Mr. WALKER's care. Her complaints, which she has had for more than two months, commenced with severe ardor uring two or three days after connection, and a discharge occurred during the ensuing week. She has had a bulo in the lest groin for two months, which gives her but little pain; there is an ulceration in the mior commimure of the vagina, which she has had for three weeks, and three or four amall condylomata at the edge of either lablum, which have been there for the same period. She has taken no medicine. Her mt symptoms are, a profuse thick yels discharge from the vagiou, scalding in terition, &c. Her general health is not very good; there is much shortness of breath; general uneasiness about the chest; with plearitic pain over the right side. The bowsis are very much confined. The catasenia have been absent for one month.

the was put upon a purgative plan of plied to the bubo and condylomata.

19. The scalding has nearly gone; the ers in the inferior labial comminure pro-ishin a turned edge; a small bulg is pre-senting itself in the right groin.

26. The bowels are very costive, and she is been ebliged to take large doses of aprient medicines (Computed Decariton of nes and Rhyberd) to keep them open. She has also suffered much from weight and

pain across the forehead.
Ageil 3. The bowels have been better rigidated lately; the genorrhead discharge is self sentimes talek, yellow, and profise, is

t, in fact, its recognited are greenally re- quentity, and there is slight scalding in cold as much credit on the surginu, and michaelides. There is sinch excernation attended with much less danger to the from the plorestion excepted the critice of the training of the critical state.

12. The properties gian of treatment has see contlined with much relief to all the rapping phasest, both internal and external. The std pain over the forchead and cyce sometimes returns, resembling in the severity of its attacks the low agree.

17. She has had no return of pain in the head since the last report; the discharge is the discharge in the control of the co old pain over the forehead and

accely gone; the sociding has subsided, and the ulceration and excertation are healed.

She was discharged this day.

In the work LANCET of last week, RODERICK MACLEON, the amiable editor, compiler, or fabricator, of that weekly bundle of stundity the "Medical Gazette," "confirms" all that we have said respecting the application which was made to Mr. Lieron, respecting the Chair of Surgery in the University of Edinburgh, and concludes his notice by observing, "With respect to "the gentleman by whom the invitation " was sent to Mr. Liston, it now appears "that a Mr. Drox was the individual;" and then, echolog THE LANCET, RODERICK myr. -"This is the whole of the matter." Here, however, the amiable mind of Hournick will be gratified on discovering that be has committed another mistake, as it is not the whole of the matter. The gentleman whom he designates "a Mr. Dick." and who wrote to Mr. Liston, is the Convenie of the Town Council of Edinburgh. Further. we may state that it is known in Edinburgh. that the Lord Provest applied personally to Mr. Lauron, when that gentleman was intely in Edinburgh, to ascertain if Mr. Learon would take the Chair of Surgery; and the magistrate who takes charge of the Collège affairs, and who is CHAIRMAN of the College Committee, addressed a letter to Me. LIBTON, in which was contained a sign inquiry. Nothing, therefore, than the following facts, vist ron having been consulted. clined the appointment, for Crastus Bress was then "electricity" and the distinguished lanicht, 'see'lle proof a favourable entities personnel dis Collegation the Council,

To the Editor.—Siz.—On Wedn Dec. 23), at the Bellin of an Hospital, a known to the modical profession are great integrity that distinguishes his seedings of all its members, the first contest for professions place. A young law some knotty points at the Board, in rundry caustic reflections which proved to he very unpaintable to a physician of some notoriety, who replied in his customary manner, and, on resuming his seat, declared that every word spoken by the lawyer was altogether false. The lawyer did not approve of this mode of arguing the case, and on rising, declared the fluent doctor, with three emphatic iterations, to be neither more nor less-I blush to say it - than "a liar." Little mure beyond a few apologies to the Board was said, and the doctor retired-to look it was whispered-for "a friend;" but the surnise was wrong, for next day the follow ing pithy dialogue was heard. Doctor, I suppose you have been to Chalk "What!" replied Dr. Farm this morning." S, with most feculent look, " to fight with a t-d? No damme." LECTURES

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL.

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculte de Médecine of Paris.

LECTURE VIII.

HEMORRHAGE OF THE CEREBELLUM. LESIONS OF SENSIBILITY IN HEMOR-RHAGE OF THE BRAIN.

In our last lecture, gentlemen, we also touched upon hemorrhage into the various points of the cerebral hemispheres, and having discussed the functional disorders accompanying each lesion, we passed to the cerebellum. We now propose to continue the history of sanguineous effusions in this latter portion of the cerebro-spinal axis, and in so doing we would demand not only your into several details on this subject, that may about to investigate has not been studied by many writers, it therefore requires a minute thalysis of the cases which we have been able to collect in the records of the science; these are not numerous, our task will not therefore be very long. We are acquainted with only thirty-two published cases of hemorrhage into the cerebellum. Let us see what we can learn from a careful analy-sis of those cases. In layertigating the subthe case; experience demonstrates, that in the case of creeked homorrhage? 2nd, is crossed. The lesion of motility occupies supposing the existence of paralysis with the side opposite the effusion. This ayou see, is the same effect produced by effusion the context of the case of the c

itself; have we paralysis on the same, or on the opposite side?

As to our first question, if we would decide it simply by à-priori reasoning, it is a much more difficult one than you might at first imagine. We are not sufficiently acquainted with the physiology of the cerebellum; experiments have not determined, in any thing like a satisfactory manner, the functions which belong to this portion of the brain; we are, therefore, compelled to rely almost exclusively upon pathological observations. and we shall presently see in what manner they resolve our question. As to our second question, whether paralysis takes place on the same side as the effusion, or at the one opposite to it, if we would determine this point also by à priori reasoning, we must examine anatomical facts; and what do they lead to? To the conclusion that paralysis should manifest itself on the same side as the lesion, in cases of hemorrhage into the cerebellum, because its fibres pass to a part of the spinal marrow where there is no intersection as in the pyramids. If, then, we adopt the conclusions to which anatomy seems to lead, we should say that the loss of motion is collateral for cases of apoplexy of the cerebellum, because here we have no intercrossing of fibres; it is opposite in cases of cerebral apoplexy, because the attention, but something of indulgence and fibres passing from the hemispheres interpatience; we shall be compelled to enter cross at the superior part of the spinal marrow, in its anterior pillars; however, we appear tedious. The question which we are beg you to remember what was said upon about to investigate has not been studied by this latter point in our last lecture, when we endeavoured to overthrow the anatomical explanation hitherto received, and to show that if hemorrhage of the cerebral hemispheres does produce loss of motion in the opposite side of the body, the reason of the phenomenon escapes our knowledge.

I have just told you that anatomical facts would lead us to conclude, that in cases of effusion into the cerebellum, the paralysis should manifest itself on the same side of the should manifest itself on the same side of the body; this, however, is far from being

solve the questions we laid down a little while ago. Let us assemble our facts together, examine and analyze them, and endeavour to ascertain some general principles, by carefully comparing what has cases just alluded to, we find only three in been observed by others with the facts of our which no paralysis existed. The first of own experience.

a basis for our conclusions, are published in Midicale for 1824, page 70. median lobe of the cerebellum; six of these ever, it is right to observe, that this case is are related by M. SERRES in the eleventh not sufficiently exact to be conclusive. The volume of his anatomy of the brain; the author does not say whether he had examined other is by DANCE, in his memoir on acute the patient from the commencement, at the hydrocephalus, printed in the Archives de date of her first attack. She might have Médecine, January 1830. In none is any been paralytic then, and have recovered the particular mention made of the state of mo-motion of her limbs. This case, then, mere-tion in the limbs. Three other cases refer ly shows, that at a certain period of time to hemorrhage in one or other of the lateral effusion into the cerebellum was not accom-

briefly noticed in Dr. ABERCROMBIE's work tation. Here no paralysis existed, although on diseases of the brain, page 238; here an effusion of blood was found in one of the

Thus, out of twenty cases in which the of motion. There remain now two cases, we find only three where motion remained, of motion. There remain now two cases, we find only three where notion remained and in those the effusion was double, occupying both hemispheres of the cerebellum at the same time; one has been published in the existence of paralysis express! at the same time; one has been published in the existence of paralysis express! is answered, "Does paralysis accompany given without any details whatever. The last case is related by Morgagin in his work "De sedibus et causisque morborum." the seat of the paralysis? The answer; He found the individual dead, and the upper limbs strongly contracted. This is too imperfect an account to afford ground for any deductions. Hence we have only twenty lint the cerebellum nearly as the find only three where notion remained intact; in all the rest, viz. seventeen, we find only three where notion remained intact; in all the rest, viz. seventeen, we find the existence of paralysis expression, then, is answered, "Does paralysis accompany effusion of blood into the cerebellum?" Yee, last case is related by Morgagin in his very contracted. This is too imperfect an account to afford ground for any defluctions. Hence we have only twenty lint the crebellum existence of paralysis expression in the existence of paralysis expression.

What was the particular seas of the Hemorrhage ?

with another? Let us again examine our and the cerebellum. Let us take the first facts. Of the seventeen cases accompanied division and ask, by hemiplegia, one only acknowledged for its cause an effusion into the median lobe. This case is reported by M. Gujor in the journal which preceded the Lancate Froncaise, in, I think, the old Clinique des Hopitaux, t. 1, no. 70, page 110. In the sixteen remaining cases, the effusion was situale in one or other of the lateral lobes. Thus we have determined two points; first, that paralysis exists; second, that it exists in the form of hemiplegia; and, finally, that TAVERNIER, in his thesis on loss of memory, in seventeen cases of hemiplegia determined sustained in July 1825. We must examine by effusion of blood into the substance of the this fact with some care, as it is unique—the cerebellum, one only occurred with hemorrhage of the median lobe, eleven of the good many facts of an opposite kind.

The individual who forms the subject of

which we have already resolved with respect time, in the year 1812, with an access of if this hemiplegia, existing, as we have tion in the limbs on the left side of the just shown, in sixteen cases, manifests itself body. Eight years passed over without the on the same side as the lesion, or opposite recurrence of any accident. In the year to it; in other words,

Is the Paralysis of Cerebellar Apoplexy direct or crossed !

Let us have recourse to our facts as usual. lesion was discovered in the left side of the body eleven times; eleven out of sixteen, this latter evidently corresponded with the crossed paralysis; two of these eleven cases, late attack, and was the cause of death, belong to M. Serres. One has been published by M. Cazes in his thesis on paralysis, plexy, shown by the reinnant of a cyst, in 1824. Another was observed by Dr. which gave rise during life to direct paraand published under his authority in the tailed, but if we study it, we find a great French Laucet for 1829, October 17th, objection, which in our eyes considerably Another, and one of the earliest cases, was diminishes its value. Thus M. TAVERNIER given to the public by Dr. HURTOR, in his did not attend the patient during the first thesis. Finally, you will find five others attack in 1812; the bistory of the case was in our fifth vol. of the Chaique Medicale, given him by the patient's wife: it is there-we should, however, remark to you, that in fore only hearsay testimony. The woman those which we have published, hemor- mistaken one side of the body for the other, rhage into the substance of the cerebrum as people often do: in a word, her evidence trially speaking, therefore, we have only must regard this case as only half a fact, ine instead of cleven cases, of sixteen We therefore conclude, that when the effu-The questions we had proposed, could only direct manner than that of M. TAVERNIER. beganswered by an appeal to facts. We Now for our second division: sampelled to assemble these from diflay before you the results.

Before proceeding any further, we have to
establish a desiran which is not without importance in the study of orrebral apoptacy.

We have lately seen an example of
this event in disease: three others are rethis event in the case of the brain.

> in the Cerebellum and in the Cerebrum, what do we observe?

three in the work of M. ROSTAN on tions, depending upon muscular action, are summer "Ramollissement." You saw that when deranged by hemorrhage into any part of hemorrhage exists in the cerebellum alone, the norvous centres. However, we shall the paralysis is opposite; but let us suppose another case. Imagine a patient with a with hemorrhage of the brain, for the interest double hemorrhage, one in the left lobe of ence exercised by effusion of blood into double hemorrhage, one in the left lobe of ence exercised by effusion of blood into other parts of the nervous centres, upon the other parts of the nervous centres, upon the right hemisphere of the brain; what should muscles we now allude to, is not well underwe observe here? Paralysis of the four limbs? Double hemiplegia corresponding to the double hemorrhage? No such thing; although the cerebellum may be full of blood, no effect is produced by it on the motions of the body. It is the brain alone which infinences motion, masking, or rather altogether absorbing, the faculty of the inferior organ; assuming to itself the whole direction of voluntary movement, and thus giving rise to a phenomenon, which, though inexplica-ble, is worthy of the most attentive consideration. The cases published by ROSTAN and others prove this fact beyond doubt, although their authors never thought of the application when they published them. And hemorrhage. The eyelids may also be deexisted alone would certainly modify the faculty of movement, loses this power as soon as it becomes associated with atrophy of the cerebrum, and paralysis is observed only on the side opposite the injured hemisphere of the brain.

We have now passed in review hemorrhage of the cerebrum and cerebellum, together with the lesions of motility that accompany it. Let us pass to effusion of blood into the substance of the spinal marrow, or,

rather, to the

Paralysis occasioned by the effusion of Blood into the Spinal Marrow.

Here the phenomenou is a simple one and easily understood, for the cause acts in the immediate vicinity of the nerves that supply the voluntary muscles. In most cases the paralysis is double, the limbs on both sides of the body are deprived of motion, and the seat of this double paralysis will naturally depend on the seat of the effusion, as the latter occupies a more or less elevated point of the chord. In some cases, however, hemorrhage of the spinal marrow is followed by hemiplegia; this is of rare occurrence; but you will find an example well detailed in the work of M. OLLIVIER on diseases of the chord. Finally, we may remark that the paralysis is never crossed, as we see is almost universally the case in ridiculous grimaces we sometimes observe hemorrhage of the cerebrum or cerebellum.

Hitherto we have confined ourselves to loss of motion as it may exist in the voluntary muscles of the limbs. It is time to consider paralysis of other parts of the consider paralysis of other parts of the we have seen one constant the body; to examine how far the other functions existed on one side of the body, and the

stood. Let us examine each of these muscular parts according to the different regions in which they are situate, and first for

Paralusis of the Muscles of the Eve.

Paralysis of the muscles, which direct the movement of the globe of the eye, has sometimes been observed; it is, however, a circumstance of rather rare occurrence; the loss of motion does not strike all the muscles to an equal degree; hence their antagonism is lost, and the phenomenon so well known under the name of strabismus, takes place; but this symptom, we again repeat, is seldom seen in cases of cerebral remark, that in several cases where we prived of motion, and particularly the levahave a different kind of lesion in the brain tor palpebra superioris. In some cases it and cerebellum, as atrophy for example, the precedes the loss of consciousness, and the same thing takes place. Thus a diminution general paralysis, for a very considerable of one lobe of the cerebellum, which if it time. We call to mind one, especially, in which the patient was anable to keep his upper eyelid from constantly falling down, for three weeks before the attack.

Paralysis of the Cheeks.

Those different parts of the face, the muscles constituting the cheeks, may also be engaged, and, indeed, this happens more frequently than for any other of the parts comprised in the present series. It is worthy of remark, that the facial paralysis always occurs on the same side as the hemiplegia, a fact which we cannot explain by the decussation of the anterior fibres of the brain in the pyramids. When once established, it produces certain phenomena that are worthy of being noticed. The paralysis is most appreciable in the buccinator muscle; hence, when the patient eats, the paralysed cheek is distended passively, until the alimentary mass is removed by a purely mechanical action, and, in severe cases, at each expiration the check becomes in like manner park sively distended, the buccinator swells wi a air, and when the latter is pressed through the mouth, it gives rise to the phenomen in popularly known under the phrase," funger la pipe," smoking a pipe. The want of chtagonism in the muscles of the face is als the reason why the patient, when he laure or talks with vehemence, &c., me

We have said that the face is constantly paralysed on the same side of the limbs. We must correct this asserting for excep-tions, though exceptions, still cales. We have seen one case of the hemistage.

100

lysis of the face at the other. This is the When the muscles of this region are paraonly case we have witnessed, and here pro- lyzed, the head inclines towards the injured hably the nervous centres were affected side, while the face is drawn to the oppowith a double lesion.

The Movements of the Tongue

are very variously modified in persons affected with cerebral hemorrhage. In the first place we observe a certain number of cases where the movements of the tongue remain intact-where it conserves a perfeet integrity of motion, while the other parts are more or less profoundly injured. In other cases the motions of the tongue are imperfect; the organ at first remains immoveable for a short time, and is then suddenly thrust out, after extraordinary efforts on the patient's part. Finally, in other cases, the tongue is completely paralyzed; the patient is unable to put it out; the slightest motion is imperceptible, and the organ remains lifeless in the bottom of the mouth, in spite of the most violent efforts to advance it. In this latter case language is lost, not from any injury which has been done to the organs of voice, but from want of the mechanical means necessary to distinct articulation. Sometimes the tongue is affected with only a partial kind of para-'ysis; the patient is able to thrust it out, but the tip deviates sensibly to one or other. side. We may ask then, To which side? Answer: The deviation of the tongue is not constant; however, we may lay it down as a very general rule, that the point turns to-wards the paralyzed side of the body; thus, if the hemiplegia exists on the left side, the tongue deviates to the left &c. The other case is infinitely more rare; examples however exist (and we have seen more than one), where the tongue was directed towards one side of the body, while paralysis occupied the opposite membranes. The motion of the tongue is generally recovered long before the limbs begin to enjoy the faculty of locomotion; thus, it is not rare to find a patient speaking without hesitation, and complete master of his tongue, in ten. welve, or fourteen days after the occurence of cerebral hemorrhage, while the lever or upper extremity is still weak and mationless. In most cases, then, the lesion motility, as regards the tongue, is much of motility, as regards the tongue, is much less considerable than in the limbs; there are however, some exceptional cases; thus we have examples on record of individuals who have fallen down in a state of apoplexy. Or recovering, the members remain weak, more; but the voice is gone, the

1.88 x 60 3

site. Paralysis of the muscles of the larynx is also extremely rare; however, you will find a very curious example of complete aphony accompanying cerebral hemorrhage, in the work of M. MOULIN.

Respiration and Deglutition.

The respiratory muscles are not affected, except in cases of a most dangerous nature, where the attack has been sudden, and the coma supervenes with intensity, in a rapid manner. The muscular tissue composing the pharynx and the larynx is sometimes struck with paralysis, but this also is very rare. We never observed it except in severe cases, and it is generally a mortal symptom; the result of this paralysis is a difficulty, or, in some cases, a complete impossibility, of deglutition, and the prognosis, as we said, then becomes very unfavourable. In certain other cases, this difficulty of deglutition forms the prominent symptom; for a considerable time before the actual effusion into the brain, we observe no other premonitory phenomenon. Dr. FLANDIN has published a case of this kind relative to a young man twenty-eight years of age, who, in consequence of violent mental emotions, was suddenly seized with malaise, and impossibility of swallowing; there was no other symptom worthy of notice until the following night, when the limbs on the left side of the body were suddenly deprived of sensation and motion : the difficulty of deglutition, with the paralysis, continued unabated for thirteen days. when the former gradually abated; the hemiplegia however continued unchanged. This is a rare and curious case; it shows in how many bizarre forms nature seems to present the same injury of the nervous centres.

Paralysis of the Rectum and Bladder

has also been observed in cases of cerebral hemorrhage; however, we believe these latter accidents occur much less frequently than has been imagined; nevertheless, it is always good to be on your guard, for the urine may be retained, especially in recent cases. When therefore you have a patient affected with apoplexy, you must be careful to examine from time to time the region of the bladder, and as the patient does not enjoy sensibility, you must not only touch this region, but ascertain the actual state of the bladder by percussion. The muscular fibres of the stomach have thing more; but the voice is gone, the paralysis of the tongue is complete, and the paralysis of the tongue is complete, and the pathot it insights a attitudate a single word. Now for constitution of the Neck in accessively read to personal hemorrhage.

Duration and Termination of Paralysis.

Once produced, the paralysis which is really the effect of cerebral hemorrhage, presents been said to partake sometimes in the gene-

itself with the essential character of persistence: it may last with unabated intensity to the patient's death, or it may diminish without completely disappearing, or it may at length disappear in a per-fect manner. When the paralysis subsides, it generally does so in a slow and gradual manner, and this is an important fact to observe, for it shows that the lesion of the nervous centres consists in effusion of blood, and not in simple congestion, when the patient continues to live for any considerable length of time. The paralysis may persist for twenty years, or even longer, and then the limb either conserves its original form, or the nutrition of the extremity becomes diminished, and it wastes away in a sensible manner. In other cases the diminution of the paralyzed member is much more rapid. We remember one example in particular, where the limb was evidently much smaller than natural within eleven hours after the date of the effusion. The paralysis, as we have said, may gradually diminish, but still at the end of many years some modification of the motility yet remains. The limbs are not active in their movements; they feel heavy, or the fingers remain habitually flexed, &c. These permanent accidents often coincide with little or no lesion in the brain. We had occasion to examine the body of a patient affected with paralysis twenty-seven years; the loss of motion, however, had gradually diminished, and at the second attack, which proved fatal, nothing remained but a simple weakness of the limbs on the left side of the body. After death we found, in the substance of the right thalamus, a hard line, of a dull whitish colonr, not more than six lines in length. This was all that remained of the ancient coagulum; a recent one existed in a different point of the brain. Another division, which we established a while ago, is that in which the paralysis disappears completely at a greater or less period after the occurrence of hemorrhage. Such a case has been seen, and thence we are induced to conclude that the coagulum has been completely absorbed, and that the nervous influence is transmitted with its original force through the cicatrix, the last vestige of an ancient hemorrhage. In some cases of the kind now alluded to, even this cicatrix is removed. In others, however, we discover more or less trace of lesion, such as cysts of various sizes, &c.; and yet, long before death, all paralysis has vanished. then, you see one and the same condition of the brain, in which paralysis may be absent or exist, according to individuals, - a new proof, in addition to those so often insisted upon in the commencement of our present course, that hesides the morbid conditions appreciable to our senses in the dead body, there are others, equally important, which escape our anatomical investigations; but office the process it is other cases it.

which add their all-powerful influence so the former, in favouring or preventing the development of functional disorders.

The Disappearance of the Paralysis, in general follows a sentain order.

What is that order? In most cases the tongue. the face, the lips, first recover their movements; the tongue ceases to deviate, the mouth recovers its natural form, and is no longer awry. After that the limbs regain the power of motion, and almost always the paralysis disappears more slowly in the upper limbs than in the lower. We have already noticed how members which have remained a long time paralytic lose their volume, or become stiff or contracted; but this is not all: in many other cases, shortly after the apoplectic attack, the side of the face and the naralyzed limbs are from time to time agitated by convulsive movements; one would think that the blood at once stimulates and deadens the nervous influence. In cases of this kind we have sometimes found the nervous pulp surrounding the coagulum perfectly free from any lesion that could explain the symptoms of irritation; in others we have seen the coagulum surrounded by injection of the cerebral substance, or by more or less softening, accompanied with coloration of the nervous pulp. Thus we have endeavoured to complete the history of paralysis depending upon effusion of blood into any portion of the nervous centres: it now remains to consider lesions of sensibility, and lesions of intellect, in connection with the same subject.

LESIONS OF SENSIBILITY OBSERVED IN HEMORRUAGE OF THE BRAIN.

During the course of this and the last lectures, we passed in review the various accidents of motility that present themselves, either in connection with hemorrhage of the brain, of the cerebellum, or, finally, of the spinal marrow; having disposed of this, the most important and interesting part of our subject, we shall now take up the lesions of sensibility which accompany effusion of blood into the cerebro-spinal axis.

These lesions are much less constant i cases of cerebral hemorrhage than those M motility, and much more difficult to tribe to any determinate alteration of the brein. However, we must follow nature as the presents herself, although we may be able to explain her actions: we shall the fore consider lesions of sensibility in brain itself; in the cusaneous ful in the organs of sense; and, fourt different mucous membranes susceptibl being submitted to experiment. It us examine

been preceded, for a greater or less period, rare, and that you cannot expect to meet sensibility. Thus the patient is subject to a weight in the head, to cephalalgia more or or less violent; he is giddy, troubled with vertigo, &c., and these symptoms frequently prelude an effusion of blood into the substance of the brain. They are, in fact, phenomena of congestion, alternating in degree, and at length terminating in hemorrhage.

Mudifications of Sensibility of the Skin

we have to distinguish under two classes. We must study them, first, as they present themselves before hemorrhage has taken place; secondly, as they are seen after the occurrence of that accident. Before the modified in consequence of cerebral hemorinstant of being struck with apoplexy, many rhage, what do we observe? In proportion individuals do not experience any modifica- as we become removed from the instant of tion of the cutaneous sensibility. This is a hemorrhage, the sensibility of the skin regeneral rule, but admits of many exceptions, turns, and is almost universally restored, Thus some patients experience a curious long before the limbs have recovered the sensation in the limbs: they feel a peculiar power of motion. Thus, in the first few days kind of coldness, as if the hands were sud- after an attack of apoplexy, if you pinch the dealy planged into cold water. complain of a pricking pain, of numbness toms of feeling; in a few days more, sensaare, in the fingers or toes, or even in the tion, though dall, exists; and, still later, the whole of the limb. The different perversions power of feeling has returned in the limbs, whole of the limb. The different perversions power of feeling has returned in the limbs, of sensibility which we have now pointed out though still incapable of executing the slightas preceding the effusion of blood, may ex- est motion. The sensibility of the various ist always in the same point of the skin, or affect in turns different points of the cutaneous periphery; they may manifest them may also be modified in a greater or less selves on both sides of the body at the same degree; the conjunctiva covering the globe time, or be confined, as was said, to a of the eye is sometimes so insensible that it single member, which is commonly the one admits the approach and even the contact of which will subsequently be attacked with the finger, without giving risc to any uneasy

times they precede the latter by a few days measure connected with a lesion of the fifth only; in other cases the numbness, prick-pair of nerves. The face and lips also suffer ing pain, creeping sensation, &c., have ex-in some cases of the above kind; in one isted many years before the occurrence of case I have seen a remarkable diminution age of fifty-two, had been struck with an sensible. ttack of apoplexy; from the age of sevenen this female experienced a sensation of ceping in one of the hands; at first interttent, the sensations at length became usion, and shortly before the period of usion, were joined by a similar feeling in e lower extremity, together with some prodromes of this kind may be prowar a very great period indeed, and perceptal hemorrhago the attack is ed by various disorders of sensibility;

hy a few accidents connected with modified them frequently as the precursors of apoplexy.

We now arrive at those lesions of sensibility which are observed after the effusion of blood has actually taken place. In many cases the loss of voluntary motion is not accompanied by a destruction of sensibility; the patient is unable to move, but he feels at other times that sensibility is either completely abolished, or merely modified, and in this case the modification of feeling usually takes place in the same side as the paralysis; in a few rare examples, however, the feeling becomes abolished at one side, and motion at the other. The sensibility once Others patient's skin, he does not evince any symp-

may partake in their turn of the general disturbance; the sense of vision remains intact in a great number of cases; however, when the attack of apoplexy is very violent, the power of seeing is frequently completely Thus you see that lost. When vision is troubled, the accidents may appear, either before the hemorrhage has taken place, or after its occurrence, or at the same instant that the patient is attacked. Before the effusion, some individuals exconscious these latter are so well marked that we can also perience various disorders of the sense of that we can which are latter are the constant the constant that the cons

have a veil or fine membrane like a spider's | various modifications of this sense be in some web drawn before their eyes, covering every measure explained. The observations we thing with a species of cloud, as when the liave just made, refer principally to loss of crystalline lens begins to alter; others con- vision at one side of the body rather than stantly see a coloured object in everything at the other; but a more general question they regard; all hodies to them are painted presents itself, vite with little red or black points. Diplopia or double vision has been sometimes observed as a precursory symptom of cerebral hemorrhage, and in some few cases this pheno-menon has been intermittent; other individuals are struck with complete blindness, and this presents the most striking premonitory sign, existing nearly alone until effusion takes place; or the loss of vision may disappear and return again at uncertain intervals. Some authors affirm that in certain cases the sense of vision acquires an unaccustomed degree of sharpness before the attack of hemorrhage; we have never seen an example of this latter phenomenon. Thus you see that several functional troubles are connected with a disturbance of the brain for a greater or less period before the occurrence of hemorrhage: they show that some change, which we are unable to appreciate, but whose nature it would be of the utmost importance to determine, takes place in the the optic ganglia, on a level with their comcerebral pulp, or in its manner of acting, long before the lesion which characterizes apoplexy.

place, vision may remain intact: it may be certain that blindness may coincide with a destroyed or weakened on one side or both. lesion, not of the brain, but of the cerebel-When the hemorrhage is very violent, vision | hum; we have before drawn your attention of both eyes is generally abolished. We have also, an the organ to the organ or the fibres of the remember, examined how far the other nerve, and pass obliquely to the visual modifications of the power. organ of the opposite side; hence we can conceive, that as the hemorrhage may implicate one or more of these different fibres, the loss of vision may take place at one tion. The sensibility side of the body or at the other, and the and surfaces is thousand

When the power of Scaing is completely abolished, can we affirm that a particular portion of the Brain is injured?

that the lesion, that is, occupies the thalami, the corpora quadrigemina, &c.? No. certainly not; if the hemorrhage be violent and extensive, we have complete abolition of the sight, no matter what region of the brain be attacked, because in these grave and dangerous cases, the whole organ is equally compressed; however, we have cases on record which show the existence of a similar phenomenon with a small coagulum, situate now in one part of the brain, now in another. M. SERRES, to whom we owe many researches upon this point of the physiology of the brain, affirms that blindness does not occur when the lesion is situate above the level of the thalami nervorum opticorum; the effusion must take place in missure; but this and several other opinions of the same kind require further examination and more imposing proofs before we At the instant the offusion of blood takes can admit them without reservation. It is simply weakened, or lost at one side of the must not neglect to mention a phenomenon body only; and in this latter case what do of the visual organs often connected with we observe? In some individuals the loss of cerebral hemorrhage, viz., dilatation of the vision occurs at the paralyzed side of the pupil; but as this symptom is merely the body; in another class it is at the opposite consequence of loss of sensibility to the retina, it comes under the same head as We have endeavoured, by a careful ex- blindness, and may be classed under the

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE III .- DISKASES OF THE LIGA-MENTS OF THE KNEW-JOINT, AND DIS-EASE SIMULATING THOSE AFFECTIONS.

Progress of Cases previously described.—Gentlemen, I shall to-day continue the subject which occupied my last clinical lecture, - diseases of the joints. (See LANCET, No. 6.4, page 528;. Respecting the four cases of fibrous capsule of the hip-joint, then described, three are well. The patients were, an elderly man, a boy, a young man, and a woman. The two patients whose cases were left for further consideration were Septimus Carter and Sophia Moath. Septimus Carter, as regards the affection of the hip, seems quite well. He was here yesterday, when I carefully examined him. Pressure over the joint did not cause any suffering. He has some slight pain about the knee, attri-butable to a slight continuance of disease of health was much improved, the pain and the fibrous capsule.

The woman, Sophia Moath, whose local disease I said had been retarded by ill health, is improved as regards the local disease. The secretions are better, but her health is so far from being good, that she wis to leave. The air of the hospital

wising to leave. The air of the hospital does not agree with her. She is to quit to-day, but I have procured her address, and shall accretain the progress of the case for your faure information.

After these cases, I mentioned two cases of inflummation of the specification of the specification of the insertions of the descipation on in which an increased that the description is to a puffluous of the ad given rise to a puffiness of the moretion. The first patient was stioned the case, and the dismissed as cured. comitue, on moving

pase of the

with tolerable freedom, the motion being a little interfered with, in consequence of the alteration of the articular surfaces.

The other case was of a rather aggravated kind, in a woman named Sullivan. The condyles of the femur were enormously enlarged, without giving way. I have seldom seen so great an enlargement without there being abscess, or more severe disease than existed in this instance. At the last report I made, she was directed to apply to and keep on the surface of the joint, the blue ointment, with soap cerate, in equal parts, adding a little opium. The subsequent report says, "the condyles are much reduced in size. There is some pain and tenderness over the lateral ligament, which pain is increased at night, but not so greatly as materially to disturb rest. The health is a little impaired. She complains of pain in the head, which might be attributable to irritation of the mucous surface of the bowels, she having slight diarrhoa, for which she was directed to take the compound chalk mixture, and a small quantity of port wine was given to her." Two days afterwards, the report says, "the bowels continued a little relaxed, but the headache is relieved; the local affection, however, appears rather aggravated," in consequence perhaps of the debility ensuing from the affection of the bowels. The pain was rather more at night, disturbing her rest, and she complained of some tenderness on the surface of the condyles, particularly in the situation of the external and internal lateral ligaments. In the space of the next four days, a considerable amendment took place. The general tenderness of the joint were less, she rested well at night, the bowels were regular, and the appetite was improved. Yesterday, the day after, I inspected the part, and was rather surprised to see the diminution that had taken place in the condyles, which is very unusual to any great extent. Perhaps the thin shell of bone had shrunk after the absorption of the internal deposit. The diminution, also, of the periosteum, which had been thickened, may have tended to account for the diminution in the size of the part.

There is mentioned in the report, " pain in the situation of the lateral ligaments."
These ligaments, in such a case, are naturally put on the stretch; for the distance of the points of attachment above and below is necessarily increased, and slow inflammatory action is thus produced. Since the condyles have diminished, the pain has altogether ceased. I expect at our next meeting to report this case as cared, so far as it to the head of is curable; that is to say, that all inflamma-ticked. The patient had been story notion has been subducd.

CARE 1.—Disease of the Internal Lateral little tendercies, and what romains is just Ligament.—I shall to-day direct your attention to one case of disease of the ligament, otherwise, also is well. Yesterday. ment of the knee, and to another which has the semblance of that disease. The first is the case of Anne Fitts in Queen's Ward, aged 36, of regular habits, an inhabitant of Bethnal-green, admitted October 29th. She said that about two months ago, after exposure to cold and damp, she experienced a dull aching pain in the right knee, increased on motion of the joint, and particularly severe at night. Leeches were applied without benefit, and on her admission, she complained of much pain on the inside of the right knee, particularly in the situation of the internal lateral ligament, more severe at night and disturbing her rest. There was some pain over the whole joint, but more upon the inner side. The leg was flexed upon the thigh to a great extent, and any effort to extend it produced great pain. The muscles which flexed the leg appeared to have got into a contracted condition. I ordered her half a grain of acetate of morphia at night, and, to relieve the local affection, a moza was applied over the lower part of the vastus internus muscle. Here you may remark, that there was a deviation from the principle which I inculcated in a former lecture. I said it was hest to apply the mora near the part which was the seat of the disease; and so it is where there is sufficient substance to admit of the exchar. The coverings, however, over the knec-joint are so thin, particularly over the internal condyle, that there would be a risk, on the separation of the slough, of the ligament being exposed, and producing a more severe a little above it.

November 7th, the report says, her pain greatly relieved; sleeps well at night; pressure over any part of the joint is not productive of much pain; the general health remains good; the moxa discharging very little. From this time to the 20th, she made very little progress; there was rather more pain in the knee, and she was unable to extend the leg. However, she slept well, the appetite was good, and the secretions were in order.

December 2. Rather more pain in the knee, which she attributes to efforts to extend the leg. Had little rest last night in consequence of this. I desired that the mora should be repeated, as the former had mearly closed, and, forther, that instead of the passive motion from day to day, the knee should be placed on a splint, with a hinge, which, by means of a screw, could be gradually extended, and that it should as they are about the be screwed out daily, but not to such an extent as to produce suffering. The application of the splint produced some pain,
which lasted a very short time however,
and she now suffere but little. There is bet

also, I had the importantly of seeing her, and I was plaused in find that the leg. instead of heing closely flaxed on the thigh, had now got nearly to a right angle with it, and, no doubt, by the continuance of the same means, we shall eventually render this part perfectly free, that is to say, the limb entirely extended.

Remarks. - This is a common case of

affection of the knee, particularly in women. The internal lateral ligament is, for an obvious reason, more liable to diseases in the female than any other ligament in the kneejoint. We find, on looking at the skeleton, deprived of the soft parts, that even in the well formed male the femur has a little inclination inwards, towards the median line, as you trace it from above to below, and that from the difference in the length of the two condyles the tibia is put nearly in a straight line, so that every person who is well formed, is slightly in-kneed. But where the pelvis is broad, as in women, and the upper part of the thigh-hones is separated to a great extent, the inclination inwards, towards the median line, the obliquity, is greater; consequently, all females who are well formed, have that particular inclination of the limb which is termed in-knee conspicuous. Sometimes this occurs to a very considerable extent. You may observe in a woman who is walking, when the pelvis is very broad, that she has a slight waddle, inasmuch as she is obliged to throw the inner condyle of one femur over the other, as she brings it forward in form of disease. So the moxa was applied progressive motion, otherwise she would strike one knee against the other. gives a rolling walk to women who have a wide pelvis, and on every occasion of forcible extension of the leg, as in running, jumping, and so forth (and it occurs also in falling), the internal lateral ligament receives the greatest stress, and is, therefore, more frequently injured, and more subject to disease, than any other ligament of the joint. Next to this the posterior ligament oftenest becomes affected, because if the extension of the leg beyond a certail degree, that ligament is put most () the stretch. There was no other evide see of affection of the knee, in the preser case, further than some general pain, whic , ho ever, was trifling in comparison w which existed just over the is not uncommon. The would placed so immediately about

201. 25 1 . 0 12

being discused, the moment the leg is extended the former is stretched and the pain more severe. From constantly maintaining a flexed position for many days together, therefore, the contraction becomes almost permanent, and considerable force is required to effect the extension when it has existed for many weeks or months. The points in this case, therefore, are, that the part diseased was indicated by the seat of the pain, -and the character of the disease by the pain being worse at night,—thus affecting the fibrous tissue. The motion of the joint without crepitus, showed the evnovial membrane to be free from any participation in the injury. She has been cured under the simple application of small moxe, and attention to the general health.

CARE 2.—Affection simulating Disease of a Ligament of the Knee-Joint.—Harriet Winch, aged 29, a cook, residing "th a family in Thames-street, was admatted into Lydia's Ward on the 4th of September. She states that about two months ago, after much exercise, she experienced pain at the posterior part of the left knee, which in a short time became so severe as to oblige her to discontinue work. She then went into the country, where, from rest and quiet, the pain left her. She re-turned to her situation, and in the course of two or three days the pain again attacked the knee with increased violence, and was particularly severe at night, disturbing her rest. Leeches were applied to the knee, but with little or no benefit. On her admission, she complained of a dull aching pain at the posterior and inner part of the knee, particularly towards evening and during the night. The posterior part of the joint was apparently a little swollen, and extensely tender. I found after her admission that I had been led into an error, probably from not quite understanding her description of her case. I understood that she had had an affection of the knee, applications and administration of the knee, applications are administration of the knee, and the content plied Joons counter-irritant and lecches, some its the country, and there recovered, the local affection is the recovery of the local affection in the second in the spelication of lecches that it appears that in stating the techniques of the terrestreet on the red to the treatment on the sen she was an out-paes the was addisordered

portions of calo-

ight, with leed

muscles as to the position which the patient which was thus relieved for a short time, maintains to enjoy rest, or freedom from pain. The patient, thangaire, lying on the back, fixes the leg on the ball, and suffers lief. She was now ordered an additional less in that position, particularly when the internal ligament is affected. The ligament of extreme heat in the knee, a cooling spiralized the recent that legs in the left in was anythed to it as the rituous lotion was applied to it, as she thought it would be grateful to her.

On the 16th (nearly a fortnight after) the pain and tenderness were somewhat less ; the rest at night was much less disturbed, the condition of the bowels and secretions was good; the uterine functions were regular. The onium was still continued, and a blister was now ordered to the knee.

23. Rest rather better at night; in other respects much the same. The former blister having healed, place another over the joint.

Oct. 6. Complains of much pain in the posterior and inner part of the joint. Omit the opium, as it produces headache and constipation. Blister repeated for the third time.

14. The pain and tenderness less; rest at night less disturbed, but she still complains of pain in the head, which is referable to the forehead.

23. The pain in the knee greatly relieved; pressure produces but trifling suffering, but the pain in the head is still very distressing. The opiate was again tried, with a stimulant, the liquor opii, with the camphor mixture. Apply the strong blue cintment, with lint, to the knee, not to be rubbed in, but merely laid on the surface.

30. Pain in the head less, but still distress-In other respects much the same.

Now from my inquiries. and seing the little benefit derived from the local remedies, I began to suspect that there was an hysterical diathesis, and the local disease was continued principally from this. I now ordered her to take the compound galbanum pill, and, with this, a small quantity of hyosciamus every night.

Nov. 4. Not quite so well; the inner part of the knee continued rather tender; rests better at night, but is occasionally disturbed with pain. She was now ordered to take the pill twice a day, and upon the affected part was to be placed the soap cerate, simply with a small quantity of opium, the blue cintment having produced some degree of superficial irritation.

11. Less pain in the knee than since her admission, but pressure over the inner part of the joint gives pain; rest at night not disturbed, and general health improved.

18. Pain in the knee again severe, and the joint tender. I now increased the power of the anti-hysterical medicine, giving the ammonia of the tincture of valerian twice or three times a day, in drachm doses.

25. Much the same. Complains of paining the knee, and rest disturbed at night. I Frequent tremore of the limb, which last about ten minutes, after which the pain is affection is not one of actual inflammation very much increased. Tenderness over the of the ligaments, actual inflammation very much increased. Tenderness over the of the ligaments, actual inflammation of the ligaments, actual inflammation of actual inflammation of the appealing tender of the internal, late her the subcarbonate of iron, still, however, ral, and posterior includes the internal, late her the subcarbonate of iron, still, however, ral, and posterior includes the pain would holding the opinion, that the affection depended a good deal on hysteria.

Dec. 2. Pain and tenderness the same; complains of throbbing at the joint; says she has occasionally extreme heat at the of an hour, followed by a corresponding degree of coldness; trembling of the limb occurs more frequently; pain is increased for a short time after the cessation of the tremors; sppetite more impaired; the secretions from the bowels are extremely offensive, of a dark colour; the bowels are torpid, but the uterine functions are natural. I directed that she should have the asafertida injection, about half a drachm of the common asafætida dissolved in half a pint of topid water, and injected every evening. On the 8th, after she had had one or two injections, she complained of some tightness across the chest; rest much disturbed; headuche remained; altogether much in the same state. Appetite a little improved. This patient, also, for the present, will quit my care, as she is desirous of leaving the hospifirst attack, did all that was necessary.

Remarks.-This has been an interesting case, inasmuch as in the first instance there was every evidence of affection of the joint of a serious kind, that is to say, acute inflammation of the internal lateral and the posterior ligaments. Perhaps the situation in which the affection was described by her to exist, prevented me from inquiring so far into the history of the case as I should have done; and this combined with a belief that she had been relieved, as I said, by counterirritation and leeches, induced me to believe that it was a case of disease of those ligaments, from inflammation, which would be relieved again by rest, and the treatment which had before been adopted. I therefore | tient's address, and she has promised to treated the case at first as declared in the report which I have read to you, and until I found that she had the nervous tremulous pulse belonging to hysterical patients, that she was frequently the subject of headache, soldom without it over the forchead, and that she had a pallid look. This, however, was a little puzzling, when we came to find that the uterine secretions were in a proper condition; but as I have seen frequently exceedingly well-marked hysteria, even in a violent degree, while the uterine functions have apparently been in a good condition, I was not so much surprised as I otherwise might have been.

Now there are further symptoms here views I had taken with regard to the knee, which it may be as first of all, the peculiar wall to moint out, that convince me the nated " hysteria" pute of

larly when the limb was at rest, and she would have complained of pain therepespe-cially on pressure; but when you come to examine the surface of the joint, it matters inner part, which continues about a quarter little where you press. If you press on the patella, on the ligamentum patellæ, between the patella and the internal lateral ligament, there, or even on the vastus externus, or internus, or on the insertion of the internal muscles, or higher up, or lower down, it is all the same; she still complains of pain. It is true she complains of pain more if you press on the posterior or lateral ligaments, or on the anterior part of the joint; but supposing that had been fibrous disease, what would be likely to occur under the unimproved condition of general health? I know that the fibrous disease would have gone on. Besides thickening, we should have had ulceration taking place, and further tumefaction, an increuse of pain, with general rigors, indicating the commencement of suppuration, instead of which you find that in one day's report the knee is detal to obtain country air, which, after the scribed as being rather better, the pain less severe, and the rest better; then a day or two afterwards, without any obvious reason, the pain is aggravated, and the local disease rather increased, and the patient thus going backwards and forwards. This is not the character of actual disease of the ligaments, unless there be some peculiarity of the constitution, some apparent change, from time to time, which will enable you to account for the local alterations that take place. This case has been one of considerable interest, and it has assumed so closely the character of ligamentous disease, that I shall take care to investigate it further. I have therefore desired Mr. WHITE, who kindly assists as my clinical clerk, to take the pame know from time to time how she on. She has gone to reside in a farer atmosphere with her parents. I have di-rected that she should take occasions by an aloetic purge, composed of aloes, hi beciamus, and colocynth. I have given her also the compound steel mixture, with a quantity of castor. This showing regularly, and I have direct to an intelligent medical ma bourhood, who will modify from time to time, acc toms. I trust and able in a short time ably of this case and views I had taken

local disease, and, again, how much the was very trifling on pressure upon the thigh-general health has to downth the continue hone. Complains of some soreness about ance of local affection, whether sympathetic the condyles, much increased at night. or real.

CASE 3.—Complicated Distance of the Knee-Joint.—There are two other cases in the house at present, which afford proof of further extension of disease of the knee. One is a man named Richard Gifford, a sailor, who has partial anchylosis of the knee-joint, a man of intemperate habits, aged 47. He was admitted into Abraham's Ward, on the 19th of November. He states that at about the year 1819, sixteen years since, while at sea, he received a severe blow on the outer side of the knee-joint, from the fall of a block. Much pain and swelling followed the injury. He was obliged to discontinue work, and then he obtained admission into the Bermuda Hospital. Bilsters were frequently applied, and blue ointment was rubbed upon the surface of the joint, and under this treatment the swelling gradually disappeared. He left the hospital as cured, but there remained stiffness of the joint. From that time till about two years ago he suffered but little, except from stiffness, when the joint, without any apparent cause, began again to swell, and was very painful, particularly at its outer part. He got admission into the hospital ship, the Dreadnought, lying in the river, and in about three months he was discharged as well. The stiffness of the joint, however, increased, and in about two months after this the affection again came on, and then he was admitted, complaining of a dult aching pain in the left knee, not referable to any particular spot. It was much in-creased during the night, and on pressing the head of the tibia against the condyles of the femor, an acute darting pain was expericaced, particularly at the auterior and inner part of the joint. The condyles of the femur were somewhat enlarged, and the motions of the joint very limited. There was slight power of flexion and extension. He cannot bring the limb perfectly straight, nor can you carry it far back. The pain was not particularly severe during the day; it seemed to extend up as far as the great was not particularly severe during the day; it seemed to extend up as far as the great trochs her, and slong this course there was some light tenderness. The limb was a little was do. The secretions were natural, and the general health good. Upon examining a cioint, I should say that there was a fifther and there baying hear destruction. of there having been destruction head of the tibia was raapproaching to the posterior

29. Much the same; can bear pressure on any part of the joint, except on some

part of the inner condyle.

December 2. More pain in the joints and at the inner part of the condyle; rest at night much disturbed; the appetite remains good; howels slightly constipated, but regulated by the house medicines. Repeat the blisters. Not much alteration since the last report; if anything, tenderness rather diminished.

Remarks .- I believe that in the first instance, that, from the description given (which, however, will hardly enable us to decide accurately), he had probably had inflammation affecting the ligament and the synovial membrane. He describes the pain to have been very great, and the swelling very considerable, so that he could not continue his work. In the Bermuda Hospital, probably from the active treatment that was then adopted, the disease was checked before proceeding to the extent of suppuration, so as to form an aperture by ulceration. in consequence of the destruction of ligament, of the synovial membrane, and of the cartilage, the articular surfaces became united by granulations, and then again the granulations were prevented from becoming essific by submitting the part to slight motion. This is not an uncommon termination of diseases of the joints; rarely, however, does it reach, in the knee-joint, this termination, because when suppuration occurs, the constitution suffers so much that the patient sinks under it.

We have, however, specimens here to show to what extent the disease may go. Here is one in which you will see the joint nearly obliterated, and the condyles of the femur united to the head of the tibia by ossific matter. Here is another preparation, in which you will see the head of the tibia resting on the anterior part of the condyles of the femur. In this instance dislocation had taken place, in consequence of ulceration of the ligament, the synovial membrane and cartilages, and the man's foot had come forward, so that the anterior part of the tibia was at right angles with the anterior part of the thigh-hone. In that position union took place, even to the extent of ossification, as you will see by the preparation. Now in the case of which I have just read the particufrom the deposition in those lars to you, there has been very slight alteration from ulceration, and why I say there has been ulceration is, because the head of the tibia has separated a little from the conblace without there dyles of the femur. The patient lay in bed, with the limb supported on a pillow, which allowed the tibia to pass backwards. This is, however, better eeen with reference to a

CARR 4.— Inflammation, alcoration, and dis healthy pra-raction of ligements of the knee-joint.— condyles of the struction of ligoments of the knee-joint.— Samuel Buffler, aged 24, residing at Blackheath, a porter by occupation, of regular habits, was admitted into Abraham's ward on the 1st of October, 1835. He states that joint discharged when about seven years of age he had some alight affection of the knee-joint, arising from a blow he received at play. About Christmas, 1834, he fell with some violence on this knee, and the accident was followed by considerable pain and swelling, so as to oblige him to discontinue his work. Leeches were applied to the part, and he remained pretty well, occasionally suffering pain in the joint. At last the pain became so severe, and the joint so much swelled, that he could no longer use the limb. After some time an opening formed of its own accord by an ulcerative process of the inner side of the leg. about two inches above the joint, which gave exit to a large quantity of pus, together with synovial fluid. Upon his admission he complained of severe pain in the knee on pressure, particularly at night; the tibia was partially dislocated backwards, and the head of the tibia was also somewhat enlarged. The wound discharged a healthy pus, the limb was much wasted, the rest at night disturbed, but the general health, considering all things, pretty fair. He was desired to take the compound rhubarb powder, consisting of rhubarb, soda, and calumba, and three grains of the sulphate of quinine in infusion of roses, and he was to take half a grain of muriate of morphia, to procure rest at night, and half a pint of porter a day, and he was placed on the house diet. A moxa was applied to the outer side of the joint, the knee was to be slightly flexed, and supported on a pillow to allow the condyles of the femur to sink backwards.

Oct. 8. The moxa discharges freely; pain

oint produces great uncasiness.

14. The condyles of the femur appear to have recovered much of their natural condition, but still, at the joint, there is a darting times you will have the destruction of carpain occasionally. On the whole, the gene-

ral health is improved. 21. Complained of no pain except on mothe inner side of the thigh produced a dis-suppuration to any extent, and no external charge of healthy pus. The size of the knee aperture was formed, and he got right is is diminished; rest good. I desired now is severe state of the distribution of the that the leg should be placed on a swing box, which would give him more facility to will find the formation of master move in bed, and at the same time allow the condyles to sink backwards.

26. Has had much pain since the leg was cavity of the joint, and then d placed in the cradle, and but little rest in itself through an opening forms consequence. A slight swelling is traced on At this time the constitution

healthy pue. This mileved the paine the condyler of the diffic still alightly project forwards, her put me miles has been placed a in the crud

11. The world in the bater side of the joint discharged white so main in the knee, pressure over the later lives not produce pain, aloops well at significant general health

18. Discharge from the wound fles, in

other respects much the same.

24. Is still doing well. December 1. Is free from pain, the wound on the outer side of the joint is healed, that on the inner part discharging pretty freely; the general health remains good. A small sore is formed on the heel from pressure. On the 7th, three days ago, he was improving and gaining health and strength.

Remarks.- In this instance the case is rather more clear, showing injury at an early period of life, producing chronic in-flammation of the ligament. He recovers from the first attack, and then, by further violence, gets a more severe form of it, quickly running from the adhesive stage to the ulcerative. Great swelling immediately takes place, great disfigurement ensues, the ligaments are soon destroyed by the ulcerative process, and unless care he taken, they quickly separate from their attachment, and the articular surfaces become dislocated. That has been the case in the preparation on the table, and to such an extent as to produce a deformity that would be hardly credible. I have seen several instances of this kind in which the tibia has been dislocated backwards in this way upon the femur. That could not place without destruction of the lateral ligaments, the posferior ligaments, and the crucial ligaments. At this time the disease has extended also to the synovial less; sleeps better, but slight motion of the membrane, and the cartilages, which have been destroyed in the process of ulceration. The extent to which suppuration takes place in these instances is very various. Sometilage, of the synovial membrane, and of the ligaments, with but little apparent formation of matter, as in the case of Gifford counter-irritation. But at other times you tensive, as in the instance of Ruffles, where the matter for the inner side of the knee.

30. Suffers very considerable pain; the swelling was increased.

Nov: 2. There being fluctuation, an opening was made to give exit to a quantity of we get of this kind in the large transfer.

hospitals, more frequently require to be re-muved to get rid of the source of irritation to save life, than to stronge the reure them otherwise, as in this pathon. When I ad-mitted this man harden has the house, there being an opening security live house, there being an opening security lives disaboration, and itrength below page 1 was doubtful whether I should not have to remove the leg, but he has some on we will, under good diet and has gone on so well, under good diet and careful attention, that I have no doubt now of the ultimate favourable termination, unless the healing process is disturbed by some accident; we shall get the granulations perhaps to inosculate, and then he able to use passive motion. This will depend, however, on the closure of the wound into the joint, for so long as that wound exists, it cannot oe right to use passive motion, because we may increase the injury by it. But as soon as the external wound is closed, passive moion may be resorted to, and he will then get ome use of the joint, perhaps to the extent hat the man Gifford has, and perhaps a ittle more. These cases will then show the prentest extent of disease compatible with he safety of the limb.

We have thus seen the knee-joint affected, and the synovial membrane liable to be disased, as well as the articular extremities in ir cancellated structure, and the liganeuts, but more particularly the internal and the posterior, in which case the disease if the ligamentous structure extends to the guovial membrane, and the cartilages beicath become destroyed. The articular suraces are removed, a new deposit takes dace, which unites the osseous extremities if the bones, sometimes by fibrous matter und sometimes by osseons matter. These ases, which proceed to an extreme degree, arely do well, in consequence of the difficulty of maintaining sufficient power in an timosphere like this, but the cases I have ited are exceptions to the general rule. ave not at present any other case of inte-est of this kind in the house, and as we save now followed this subject up in three ectures, I shall go to another subject when lexitive meet.

A rolle, published in Dr. Lombard's work a the influence of professions on sulmon ry consumption, shows that, of all its circle in the large is the inhalation of regetable emanations, which is in a large in the large is the inhalation of localities. ST. THOMAS'S HOSPITAL

CLINICAL LECTURE

ON A CASE OF

SIMPLE FRACTURE OF THE LEG; FOLLOWED BY GANGRENE.

Delivered in the Session 1835-36.

BY MR. GREEN.

Ters morning I shall address to you; gentlemen, some observations on a case of simple fracture of the bones of the leg; which was followed by gangrene, in a case that was admitted on the 6th of October last. The patient was Charles Hayling, aged 47; a flour porter, of good stature, and inuscular, though not bulky. He had been a gin and porter drinker; latterly, however, only taking porter on account of a cough. I do not know, however, whether, to care the cough; he took the porter, or left off the gin, but he had had a cough for some time. In other respects he said he was temperate in habits, and not accustomed to intoxication. While standing on the step of a door, a brewer's dray was suddenly pushed back, and jammed his right leg between the wheel and the step. He was immediately brought to the hospital; where it was found that the tibis and fibula were fractured, with comminution, at about the middle of the leg. There was considerable effusion around the seat of the fracture; and a small wound on the outer side of the leg, not however communicating with the fractured portion of bone, so that the injury came within the description of what is termed a simple fracture. There was also some grazing of the skin; and a remarkable fact is stated by Mr. Taxw, under whose care the case came. No pulsation could be felt in either of the tibial arteries at the ankle. Now this, in connection with the subsequent circumstances, is a fact worth notice. The knee was half bent, and placed on the side, and, though there was not much bruising, on account of the swelling and tension, the leg was wrapped by Mr. TREW in flannels steeped in hot fomentations. The bruising I was informed was not very considerable, though there was so much swelling and tension as to render it advisable, in Mr. TREW's opinion, to apply fomentation by warm flannels.

of localities. Next but at a location by warm names.

In the evening of the next day, the 7th of October, he complained of great pain in the limb, and appeared rather delirious, wishing the place comes in the place comes and the limb, and appeared rather delirious, wishing the place comes are location to the same of the limb and he answered questions with a location of the arms. I sauch more swellen, and the discolaration

was increased, both above and below the fraction of the man justified the remark. His counture. There is also some swelling about the castille than natural. Fifty drops of the tinctura opil than natural. Fifty drops of the tinctura opil he was very containing to that I apprehence given to him in the evening. Thus the same have have stood by we already see that on the very day after the accident, a change had taken place, which was very unfavourable. You will observe that the sensibility of the foot had become diminished, and the power of such become diminished, and the power of sustaining its natural temperature was much lessened, and that this was accompanied with constitutional irritation; at any rate some disturbance of the nervous system had occurred, which was to be regarded as an unfavourable sign.

The circumstances bring to my mind the case of a man, which indeed has been published, with a compound fracture, in which at the end of about ten days, when the patient seemed to be going on favourably, violent hemorrhage took place, and it be came necessary to amputate the limb, though the condition of the patient was very unfavourable. Indeed, stimulants were essential to bring him to bear the operation, and yet its necessity was absolute, for the loss of a very small quantity more of blood would have destroyed the patient, as we could not get at the artery. The patient being of a healthy and robust frame, and the loss of blood apparently the only cause of the depression, I injected several ounces of blood into a vein at the bend of the arm, and the man, in consequence, revived uncommonly, took nourishment, and seemed to be going on well; but ou the next day he altered and was sinking. I repeated the transfusion, but without any effect. The first untoward symptoms were, restlessness, and a desire to get up, but he was easily wandered. What change could have induced the latter symptoms which he exhi-bited? It turned out afterwards, that morthat it was this which caused the first symptoms, and also prevented the second transfusion from producing good effect. The mortification may have been partly the effect of the great loss of blood reducing the powers of the system below the requisite condition to sustain vitality, followed by the infliction of such an injury as amputation. Mortification of the stump took place, which we failed to overcome.

To return to the case before us. The foot was observed to be cold. Opium was given in the evening, and it was thought well to envelop the whole limb in a poultice.

Oct. 8. The patient is much easier. The opium had produced him a quiet night. Bowels regular, his general health maf-Bowels regular, his general manus.

Bowels regular, his general manus.

Bowels regular, his control port for the control too strong an expression after, hearing that dent. Here was the pulse was 110; however, the appearance needed what a control was

The report goes on to state that his pulse was 110, rather full, and not wanting in power; tongue clean; skin warm and moist; perfectly sensible. The peculiar wandering has gone off; it was a very remarkable symptom. The leg is now more discoloured, as if it had been severely braised. The foot exhibits many large patches, and a bluish red colour on a perfectly white ground. There is cedema about the ankle, and much tumefaction about the lower third of the thigh. The skin of the thigh is very hot, but not discoloured. The superficial veins of the thigh are remarkably charged. There is still the same want of sensibility in the foot, and an absence of pulsation in the tibial arteries. It short it became perfectly distinct that gangrene was taking place to a considerable extent; but it was remarkable that the system generally bore the injury so well. It seemed at that time scarcely to have taken the alarm. It is remarkable, I mean, as an unfavourable symptom, for very commonly you will find that where the system does not take the alarm, when there is sufficient cause for alarm, there exists some cause which is likely to interfere materially with the patient's recovery. It has been noticed, - and I think there is some ground for the observation, though it is difficult to come to any very decided conclusion upon a point where quieted; still when left to himself his mind the instances must take place under such varied circumstances that one cannot feel justified in generalizing with great confidence, -but it has been observed that pertification had occurred on the face of the sons who do not complain much at the time stump, and I do not in the least doubt but of undergoing an operation, but bear it apparently perfectly well, often do very ill after-wards. This fact seems in some degree to bear upon the case now before us. Hare was a patient in whom, although there was juite sufficient cause, from incipient gangrane, for violent irritation of the system, yet the sysviolent irritation of the system, yet the system seemed to be unaffected. I saw aim on the 8th, which was the third day, and I well remember, as mentioned in the rap it, that while the appearance of the Mante

grenous, his general health was a Well, I had to make up take the treatment. Although, in some of a favourable constitution, y had, beyond coubt, been to the use of spirituated

sider two things; the help the state of the state at this periods in the proper to appear a ferrors where rangene did not supervene, tate at this periods in the proper to appear a ferrors where rangene did not supervene, tate at this periods in the proper to appear a ferror where the periods are the supply of considering that is the property of the supply of considering that is the property of the supply of considering that is the property of the supply of considering that is the property of the supply of considering that is the property of the supply of considering that is the property of the supply of the sup tional effects which were likely to arise without that operation? I might say that a third point presented itself to my mind, which, though it did not bear very importantly on the treatment in connection with the other two questions, yet is worthy of notice, and that related to the cause of the gangrene. The limb was so jammed by a cart-wheel as to produce a severe contusion; and there was a good deal of swelling after the accident, but still, according to the report of the appearance of the leg immediately after the accident, it did not appear even probable, still less certain, that the gangrene was entirely produced by the local injury. There was no appearance, on admission, of the parts being so crushed as certainly to evidence the cessation of their vitality. Therefore, the question might very well be asked. What was the cause of the gangrene? Doubtless, the bruising was one cause; but it seemed probable that there was something more. One naturally asked then, Is any main artery so ruptured as to cut off the supply of blood? I called your attention to the fact, that there was no pulsation in either the anterior or the posterior tibial arteries; but if, for instance, there had been rupture of the popliteal artery, that might have explained the want of pulsation in the arteries at the ankle, but not, with certainty, the occurrence of mortification.

I recollect the case of a young gentleman, who, in riding a race, struck his knee against a tree, and fractured both hones of the leg. The limb immediately began to swell, and so continued until it was swollen to a prodijous size. The surgeon in attendance was orly at a loss to account for this extraor linary swelling. The patient was treated in he usual way, and after the usual lapse of me at which a fracture might be suppos d to be united, it was found that the uni n had not taken place. He was placed dridatesavay's fracture apparatus, but hatter success, the swelling did not the districture did not unite; inflam-suppuration, and abscess, supera came on a bleeding, and then it amputate the limb. And

preparation on the table, taken from the Museum, in which you will observe a clot in the brachial artery; and I recollect having heard Sir Astley Cooper speak of this case as one in which the mortification of the limb (for the arm mortified in this instance) was supposed to be dependent upon the formation of that clot; but I do not know any further particulars of the case than those which I have detailed to you. We may readily suppose that where an obstruc-tion to the circulation takes place by means of a cospulum, an insufficient supply of blood will be distributed to the parts below, and that obstruction may be the cause of the mortification.

But no such circumstances were found to exist in this case; there was no rupture of the artery, no congulum, no little specks of coagula here and there, as you might have expected. The vessels were empty; nothing obstructed the circulation, nor was there any thing in the history of the case, or in the after examination of the limb, sufficient to explain the very interesting and important fact, supposing it to have been accurately ascertained,-and I do not doubt (considering what Mr. Taxw has stated) that it was thoroughly ascertained, -that there was no pulsation in the tibial arteries. Whether that was connected with the gangrene, in the relation of cause or effect, I am unable to

Let us return then to the questions; First, Would it have been proper to amputate under any circumstances? Secondly, Whether in this particular instance it was proper to amputate at that time.

With respect to the first of these questions, surgeons, I think, are still in some doubt whether amputation should be performed (gangrene having taken place): before a line of demarcation occurs. Most of them have agreed to wait for that line of demarcation, in opposition to the opinion of the older surgeons, that amputation is a remedy against the spreading of mortifica-tion. Indeed, I think ample experience has shown that if you amputate during spreading gangrene, under ordinary circumstances, mortification of the stump generally the man appearance is a construction of the sump general part of the part of t in a man who was admitted under the care of Sir ASTLEY COOPER, mortification had taken place from anenrysm in a vessel of the arm, and Sir ASTLEY amputated without there being anything like a line of demarcation. There was a case of simple fracture in this hospital, in a maniac, who, heing troublesome here, was sent to the parish house, but with the arm properly handaged. But he succeeded in removing the splints, and mortification took place. Amputation was there had recourse to while the gangrene was still extending; and it did not reappear in the stump, but the man did perfectly well. Taking all things into consideration, we may perhaps say, as a general rule, that it is proper to wait until the line of demarcation has shown itself; while, at the same time, there are certain cases where you may amputate previously, supposing the mortification to arise from a cause which is entirely within the part and only relating to that part. Have a care, however, that the exception which you make to the general rule shall be perfectly in point.

And now, to come to the next question, whether, in the particular case before us, amputation should have been performed, although the system was not affected, and although the mortification might have been referred to the precise spot implicated. But I was very much in doubt whether the mortification could be referred solely to the local injury, and I am inclined still to think, though the issue of the case is before us, that such was not the case. The man was a great drinker, and perhaps, though I have no means of exactly determining the point, some alteration had occurred in the state of the large vessels. He certainly did not appear to have any disease of the heart, yet there might have been such an alteration there or in some of the large vessels as would produce a change in the circulation. therefore appeared to me exceedingly doubtful, to say the least of it, that the mortification depended solely on the local injury. However, his appearance on admission being good, and not such as indicated that mortification was pending, I considered that we should give him a better chance of recovery by waiting until the parts should be in such a state as would allow the amputation to be thought that advantage might be safely performed, so far as regarded the prospects of healing, and until such symptoms appeared as would render the opera- the tinctura opti, and then tion imperative, but which did not exist at | tinctura hyes the time I was considering these matters.

On the 9th of October I found that he TRAVERS. was not so well, and had lost his appetite. 13. He slegs

tification arises purely from local causes, and He had slept tolerably well during the past is dependent upon circumstances entirely night, except when disturbed by shooting within the part, you may amputate before pages in the leg; the limb was more gene-the line of demarcation has occurred. In-trally bluish, and a part of the skin above stances might be adduced where this plan the interpretable of the skin above has been successfully resorted to. Thus the fit there was some token of segaration. the injury presents to the part of the part of the limb On the outer and back part of the limb there were several small restantions containing serum. The bluish appearance gradually subsided into the natural appearance, upon the thigh. The tumefaction had not increased, but the swelling extended to the upper third of the thigh, and there was a curious sensation in the femoral arter if air had been diffused through the cellular tissue. The other parts of the thigh had a doughy feel, but did not pit on pressure. Pulse 108, rather jerking, but not capable of sustaining pressure. The tongue was slightly coated; the howels were regular. I omitted to say before, that as his habits had led me to infer that his strength could not be supported without his accustomed stimulant, I ordered him four ounces of gin daily, and full diet, directing the dresser to watch for any febrile symptoms, and then diminish the quantity of both, in order that the actions of the system should not be roused into tumult.

On the next day the quantity of gin was ordered to be increased to six ounces, with a little port-wine mixed in sago or gruel. think it makes a great difference, whether stimulants are mixed with food or not. In food they do not seem to exert the same influence in rousing the action of the heart; they do not have the immediate effect of diffusive stimulants, for they are not then so concentrated.

On the 11th it appears that he had slept well during the former night. He was without any appetite. The state of the limb was not much varied. The foot was more bluish, but had some little warmth and sensibility remaining. The leg was dark blue. The thigh was emphysematous, and rather bluish; pulse 104; tongue whitish; bowels relieved last evening.

12. The report states that he did not sleep last night, in consequence of muq sharp pain extending down to the for There is considerable vesication on the on the outer side especially; but little sation below the ankle; the swelling o thigh has increased since yesterday now extends to the groin; the wi pulse 100; tongue clean; borskin comfortable; appetite using some other stimulant, and of the carbonate of ammonia, and

14: I made to day three incisions, each about two inches in length; one on the front, one on the outside of the leg (both through the living and the dead skin), and n the outer side of the thigh, in consequence of his having experienced a good deal of pain, which seemed to me to originate very much in the tension of the parts. I also thought it probable that there might be some matter or sloughs under the skin.

15. Much relieved from pain by the incisions, and feels better. The line of separation has commenced on the outside of the

16. Had no sleep last night, from great pain in the middle of the leg. There is a slight sensation of fluctuation just behind the middle of the leg. I passed a lancet deeply into it, but no pus escaped. The discoloration of the leg had not extended; pulse 108.

17. Passed a good night, but his constitution is now beginning to suffer. The cheeks have a patch of pink on them; skin hot and dry; tongue dry in the middle, with moist edges; pulse 116, full, and irritable; bowels He has become thinner, but is in open. less pain. The separating line is still pro-ceeding. The leg, just below the knee, is extremely sensible when pressed upon, and the emphysems now spreads over the whole front of the thigh, which is more swollen.

18. Much the same; pulso 118, jerking. The lower part of the leg is now quite black. An irregular line marks the boundary

of the gangrene.

19. Slept tolerably well last night, and is in less pain, but his features are beginning to shrink, and there is more hectic flush upon his face; pulse 120; pain diminished; and the line separating the living from the dead parts has slightly commenced. There is a plentiful but thin discharge from the thigh.

20. The separating line is now quite disthat; he slept very well last night, but his ters are beginning to flag; pulse 120, erling, and very easily compressed; bowels

ar; appetite impaired.

He wandered much during the night, lowards morning became sensible, i his manner is rather hurried; be is determined to amputate, as the only chance of saving his life. I now found the appearance of sepa-ment rease marked, though not even the state of eration was not

move diffused, but no distinct line of departy vious that they were smalls to carry him cation; the crepitation has increased; guies; through the process of separation of the 108, full, and telerably firm; tongue whitish; limb. Accordingly the ampustion was per-Ordered a mutton-thoughtful the same of the and cellular tissue at the back of the thigh were full of adhesive matter, and glued firmly to the fascis. Fur excepted on cutting through the muscles. There was rather more venous blood than usual lost, and he became rather faint. Brandy was administered, but he appeared sinking. Three ligatures were applied, and a strap of adherive plaster was used, pro tempore. He was taken to bed and a drachm of tincture opii was administered. I remained with him for some time after the operation, for he certainly was in a state of complete depression from the operation. It was evident that the system had received a very severe shock, and though the quantity of blood lost during the operation was not very great, yet I apprehend that it was very sensibly felt. There was one symptom which you will often see in persons who have lost a good deal of blood, an anxiety about the breathing, as if there was a difficulty in filling the lungs, a restlessness, a turning from one side to the other, a gasping with the mouth, and, withal, considerable depression. However, I left him, with directions that he show be supported as far as possible. Diffusive stimulants were given ad libitum, in order to keep the powers of the system going until, if it was possible, a reaction might take place, and some symptoms of restoration should appear. At seven o'clock, having taken brandy twice, he was still very low : the pulse was very quick and weak, but yet he rallied after each administration of the brandy-and-water. The stump had been dressed, and there was but little oozing from it. Still, notwithstanding all these means for rousing the system, he died at half past nine o'clock on the same evening, without having exhibited the slightest appearance of reaction, although by that time he had taken nearly half a pint of brandy. An attempt was made to give him forty drops of the liquor opii in a camphor mixture, a short time before his death, but only a very little of it could be got down.

Then came the examination of the limb. but I am sorry to say that there was no examination beyond that. I wished to look at the heart and great vessels, but the friends would not allow it. It was found that a setangular portion of the tibia had been detached and driven backwards, being in close connection with, though not pressing on, the posterior tibial vessels. Three inches below that, the bone was surrounded by a considerable portion of lymph. The arts. ries on being slit open appeared to be healthy, and contained but listic fibring. The mus-Life limb. As this cles on the other side of the leg size seemed to be healthy. The fibula was fractured thing, and perfectly obleelus, a considerable way below the franchistic in the knowledge of diseases of the ture of the this. On cutting into the tip the have not been tery aucient. Dever knee joint, bloody matter escaped, and the state of approximately with the continuous substance was a little distributed diseases in the fashion of the day. cartileginous substance was a little disorganized.

Could any other plan of treatment have been adopted in this case, with a better chance of saving life? Was any thing omitted which could have contributed to his recovery? Really, on reviewing the circumstances, I am not aware that a different plan could have been adopted. The man was intemperate; he had received a severe contasion on the leg, accompanied by fracture; and, apparently, partly from the contusion, and partly, perhaps, from the state of his circulation, induced by his habits, gangrene occurred. Had amputation been performed when first the operation suggested itself, the probability is that gangrene would have taken place in the stump, or that the patient would have died from the effects of the operation, as he did at a later period. The plan of treatment consisted in supporting, without rousing to turnaltous excitement, the powers and the functions of the system ; and they were tole. rably well sustained until the parts began the line of demarcation from adhesive informed, the actual separation of the dead under an overwhelming injury. Under these unfavourable circumstances amputation was performed, when it could no longer be de-layed, but, unfortunately, the state of the system during the amputation, combined with the shock of the operation, produced the unsuccessful result which we have to

DIAGNOSIS OF DISEASES OF HEART.

regret.

ON PALPITATION,

MERVOUS, PLETHORIC, AND SYMPTOMATIC. By JOHN FOSBROKE, M.D., Physician to the Royal Dispensary.

Ters is so prominent a symptom of affections of the heart, that the physicians of yore lumped together all diseases of that farther in his footsteps, than those emin organ under the term "pelpitation," just egotists in England with the been as I have known some modern professor or pupils, and have the state of the contract of the cont

described diseases in one manner as no uny hair is " at one time, that every being distinct of being langued out of the polypus, mortification of the bowels came in fashion; and, when a particular of the polypus, and when a particular of the polypus, and when a particular of the polypus. tient was dead, the surgeon was prid to make out the disease incurable. Dr. Parry will stand high in the estimation of the profession, so long as that man is considered the greatest physician who collects the most facts, and reasons best on those facts; but he blended together hypertrophies and dilatations under the general term "enlargement," giving here and there some distinctions between the two in the course of description. Mr. Abernethy went nearer to the wind, and knew, in a general manner, the two brief differences of thickening and dilatation, and attempted to distinguish these, and almost all diseases of the heart, by the pulse. I remember him, in his striking and facetious lectures, talking of " aggrandizement of the heart's substance, being attended with aggrandizement of the heart's action, a pulse vibrating like a cartrope, and increase of the heart's bulk by to separate, when the aspect of the case rope, and increase of the heart's bulk hy was not at all favourable; and although dilatation, with diminution of its nction. Where the action is increased, the heart fammation, had never been completely is enlarged in its diameter, the carotida pulsate, and both those arteries are dilated, to from the living parts only took place carry off the quantity of blood forced upon partially, and, in the course perhaps of a them. Ossifications, strictures, and confew hours, the patient began to pass into tractions of the annulus venous are attended that state which Mr. Hunters so expressively ed with an extremely weak and quick pulse. called "symptomatic of dissolution" produced | And for why? the arteries are fully supplied with blood! Because it cannot make its way through the contracted heart. They interfere with muscular power, diminish the heart's contractions, and give rise to a pulse scarcely to be felt, and to pain in the part." (M.S. Notes of Anat. Lect. on the Heart, by J. F.) So talked Mr. Abernethy, and practitioners continued for some time to discriminate diseases of the heart through the pulse, like the Chinese, who pretend to discover all diseases through the same medium. I apprehend it is no better guide in the one case than the other.

Beddocs says, that John Hunter did more for the advancement of malical science, than the whole University of Idinto his day, and, if he had had more than and fewer Oxford prejudices. he will be a large to the second seco said, than all the medical corps schools in Great Britain.

Since Hunter, the French have ad e eminent as I have known some modern protessor or pupils, and have his single Medity on their extres doctor retires himself from all manner lips. It was rectained to the feature of throw a broad first of the feature of throw a broad first of the feature of the hoar, and the first the lipself game before him. Our approaches to prebeautiful precision, between hypertrophy cand dilatation, and the show their various indifferently, the morbid action which accusses, combinations, and distinguishing companies those effects, and arises from the characters. "The French," says Dr distinguishing the circulating and nervous systems, "attend very such to, and on the stems. My object is, therefore, to show how very accurately, the symptoms and pages disordered vascular and nervous action afarrong, "attend very much to, and opinion very accuracity, the symptoms and mana-logy of diseases; and, generally specially, their diseases; and, generally specially, their diseases that the second of the course, but they seem as if their only officet, was an find out the disease, without any reference to its relief or cure, for their treatment of disease is most miserable." Truly enough, their treatment of scute disease has been miserable, comparatively, with our own, but they have had different institutions, and, since the ridicule of Moliere, strong prejudices, to deal with. In this respect they appear to improve every day, and in the treatment of chronic discases, I am disposed to think they are advancing beyond us in the extent, minuteness, and correctness, of their therapeutical experiments. But, whether our inferiors or equals in treatment, they have supplied ourselves and all Europe with that whereof we lacked most grievously. "Among physicians, equal in other respects, those who are brought up to distinguish internal affections with accuracy, must always be superior. There is almost as much difference, in the cultivation of this fundamental talent, between some of our schools and that of Paris, as between the chemistry of Glauber and that of Lavoisier. Such a foundation being once laid, the proper structure may indeed not be raised upon it. But no other foundation is fit to receive the edifice of medical knowledge; without it, the superstructure must be both irregular and misubstantial" Dr. Beildues;

It appears to me, from what I saw when I was studying at Paris, and from the tendency of the clinical observations in their publications, that they so much value the study of "organic medicine," by which they mean diseases arising from changes of structure, that they pass over the more numerous diseased actions which depend merely on changes of function, as almost unworthy of regular application, because they are more uncertain, bewildering, and conjectural. In this country, we are bound to attend to em, because they form the chief part of of practice. Medicine means, in England, the "Sick Trade," and the pride of science othing in comparison to the pride of cy-getting. More physiological dephysicing det theories; and sometimes a spinning a cobweb, containing to make a fortune. I think that the French

feet the heart in both aganic and functions

I observed, in the last communication, that there were three kinds of palpitation, the nervous, the plethoric, and the sympto-

The original cause of servous palpitation is, that the heart is the organ of the most universal sympathy (John Hunter). Irritability is variously bestowed, and variously appointed, in various parts of the body, but in all creatures the heart is the most irritable part (John Bell). It is the first organ that receives morbid impressions from the brain, when that organ and the nervous system are disturbed by the mind, or by phy-tical causes. It is the part most directly connected with mental emotions. (Dry. Haighton and Blundell, Notes of Physiological cal Lect., by J. F.) What is more familiar than the different degrees of irritability and irregularity of the heart's action, which are produced by profound and protracted emotions of anxiety, grief, and despondency, or what more common than the sudden suspension of every commotion of the circulating system, and the return of a calm and placid state of the whole frame, when the influence of the depressing passions is re-

The plethoric kind arises from the influence of the blood. Inasmuch as muscles are irritable in proportion to the supply of blood, and deprived of irritability, and even paralyzed, by the want of it (Drs. Haighton and Blundeli), the heart, as it is supplied with a greater quantity of blood than other muscular structures, is endowed with the principle of irritability in a greater degive. Secondly, as the blood is the proper stimulus of the heart and the heart's action, it may be over-stimulated by the excess of its own blood (Mr. H. Cline). Thirdly, according to some, the exciting power is relatively increased, not only in proportion to quantity, but quality; that is, in proportion as the blood is fibrinous, as the clot is more than the scrum (M. Andral).

The original cause of the third kind, or symptomatic palpitations, is the existence of any disease of the heart itself, or of any organ whatsoever, near or remote, capable of opposing an obstacle to the circulation (Prof. Rostan), or exciting sympathetic irrilynn iota of truth, catches fools enough | tation of the heart. Alterations of the heart will often depend on impressions made by actually to much by the spirit of remote organs; in irritation of the brain, its state that insulties into distinct the basis. They look too exclusions are accelerated (Prof. Macring. Ms. Notro of Pathalogical Lett., by J. S.). remote organs; in irritation of the brain, its MS. Notes of Pathalogical Lect., by J. K.); it is linble indental ha, thickenings, alla- it is more, more most minute structures,

 $\mathcal{H}_{\mathcal{G}^{-1}(\mathcal{G}^{+1})} = \mathcal{F}^{*}$

for its sympathics are most extensive. (Prof. Alison. MS. Notes of Clinical Lect., by J. F.)

How are these three kinds of palpitation to be distinguished from one another? In so far as we are capable of discriminating them, it will generally happen that we shall be able to discern functional derangement from organic disease of the heart. Some may regard palpitation as a matter-of-course symptom; but upon a thorough knowledge of it, upon a comprehensive view of the se-veral kinds, and upon a clear distinction between such as have a nervous, vascular, or symptomatic origin, not only an equal knowledge of heart cases must turn, but the practice also must frequently depend-Common nervous and symptomatic palpitations are of every-day occurrence; but are there not cases of mixed nervous and plathoric palpitation, which assume the characters of hypertrophies and other organic affections of the heart? and is it not a chief point to know all modes of distinguishing them. " for it is a great matter to be able to say whether there is any structural disease or not?" (Dr. Macintosh.)

I. Nervous palpitations have been great (M. Rostan) .- Dunbtful again .- J. F. stumbling-blocks in the way of discriminating organic from functional derangement of disease, more frequently affect the auricles the heart. Pathologists inform us that we than the ventricles, and the right auricle shall know them by the following signs and than the left (Professor Home).

circumstances :-

habit, and therefore in women more than in tutes that kind of palpitation which I have men (Prof. Home); and in young, nervous, termed the "plethorie" in contradistinction and irritable persons of both sexes, in parti- to the "nervous." cular states of the brain and its connections (M. Rostan); in fact, in hysterical females, bypochondriacs, and persons called nervous

2. Under all these circumstances of constitution, sex, and age, the usual exciting causes of the disturbance of the nervous aystem and of the beart, are, moral affections. intellectual labour too long continued, losses of all kinds (M. Restas), the excessive indul-gence of various passions, stimulants, vio-lent exercise, accessive depletion, the par-ticipation of the heart in the general dis-ordered new action of the system in bysteris, chiescasis, and epilepsy (Dr. Mac-jatosh); so that the principal causes are, mental or cerebral excitement, depression, or irritation.

3. They happen to persons who have expertenced other nervous phenomena (M.

4. They are at first slight and transient, and are at last reproduced more frequently the heart is seming more irritable (Dr. civical). When, owing to a particular state of the brain and its dependencies, are only instantaneous, they produce no cavities of the heart and in cases attend

profound exteration of health, and they supervene almost suddenly (M. Rosten).

3. The pulse is quicker than netwest, from

84 to 96 (M. Laennee).

6. They are frequently most distressing when the body is in a state of regular during the first part of the night, with all an prevent sleep for many hours (Same).
7. There is sometimes a semistion of in-

ternal sgitation, particularly in the hear and abdomen; and, as in hysteria, the prine is

copious and limpid (Same).

8. They are less troublesome, when the patient is taking exercise in the open air than at other times (Same).

9. The sound of the heart's contraction, though clear, is not heard loudly over a

great extent of chest (Same).

10. Palpitation is without impulse : that is, "the head of the auscultator is not sensibly elevated, and by this circumstance it is distinguishable from the increased motion and shock of hypertrophy (Same) .- This is a doubtful observation .- J. F.

11. They are known by the absence of the signs that accompany discuses of the heart

12. Palpitations not depending on organic

I shall endeavour to show in what re-1. They are most readily excited in per- spects these phenomena, whether derived sons of a nervous and sanguine tempera- from the history of cases or stethoscopic ment (Dr. Macintosh); in persons subject to signs, are true, or more or less equivocal. extreme mobility, of nervous and debilitated But beforehand, I shall state what consti-

Palpitations, in general, independent of organic disease, have been considered by most pathologists "a purely nervous affec-tion." Dr. Macintosh observes that though he has never been obliged to open a vein or apply leeches, he "can readily imagine a combination of circumstances, which will render the one practice or the other advisable : for instance, in a young plethoric person, who is affected at the same time with some febrile movement." I have before observed that this notion of palpitations being so universally "a purely nerve is affection," has been carried too far. I h ve seen enough to convince me of their con ring frequently from vascular engorgen and of the cavities of the heart. I seen a double cause operating in the s case; a plethoric state of the hear with disordered nervous action. those physicians who have compiled on the practice of physic, have glasse the distinction between the nerveus and the heart landsming more irritable (Dr. plethoric kinds. Dr. Parry, whe was a verseinsted). When, owing to a particular profound and logical languist into the district of the brain and its dependencies, access of the heart and circulation, and the profound and logical lands of the land of the lands of the land of the lands of the land of the lands of the

with pain in the left same, resembling angina | remarks, of a plethoric state, more blood politoris, he conceived that the existence of palutation was a proof of the disease of palpitation was a proof of the not being angina, but one of those anomalous affections which originate from blood bring so accumulated. But he blood being so accumulated. But he considered that the effect of the excess was not always the saids. The first and most obvious consequence was to trimulate the healthy heast to inordinate action, which, after a time, was liable to be followed by a proportionate diminution of action, whence syncope and even death might ensue; on the other hand, another and immediate effect of such accumulations was to induce a more sluggish action of the heart's frequency and force, which has been observed in persons of full habit, and in the subjects of angina pectoris, during the time that the accumulation is produced by muscular exertion. He ascrihed these two opposite effects of the same cause, to the difference of predisposition caused by different local causes, -fatness, extenuation or flaccidity of the muscular substance of the heart, ossification of the coronary arteries, or mechanical pressure on the brain, and certain narcotics, predisposing to torpor and retarded action of the heart, to organic causes, as preternatural enlargement,-to acute causes, as inflammation, vascular fulness of the substance or internal membrane of the heart,-to chronic causes, as the irritability arising from want of bodily exercise, or, as he terms it, "defect of due exertion of the voluntary muscles," predisposing to inordinate action. To this last and most important observation he adds that the predisposition to over-excitability of the heart from fulness of blood, "accompanies that condition of constitution which is usually called 'nervous,' in which the heart is peculiarly disposed to be affected by the whole train of mental emotions."

Several cases which I have seen of late. and more especially the very important circumstances in the two by no means familiar cases of Gwynne and Howls, which will be given, fully bear out these two last important and correct propositions. They shed much light on the origin of palpitations, inmmation, and enlargement of the heart, and they bear out the evidences which I we had of mixed nervous and plethoric pitations existing in the same case. tan observes that where there exists no mile lesion, a plethoric state sometimes the lesions more or less strong. Pro-lesions noticed their concurrence, Sectionic or inflammatory diathesis, comity of treatment by blood-letting w diet. M. Martinet also distinguishes on actions from plettors and con-

being formed in the economy, and, cons quently, a greater quantity being passed through the heart in a given time, an excess of action, and papirations, may results from it, which may either disappear with the plethoric state, or, if they parsist, at hast produce hypertrophy, on the same principle that any muscle whatsoever will include the control of the control crease in thickness under the influence of violent exercise. Adding much more than this, he gives a striking case in a blacksmith. and points out what is exceedingly important, the manner in which vascular engorgement may be confounded, through the identical character of the signs, with enlargement of the heart from thickening, now known by the barbarous term hypertrophy. The forthcoming cases will illustrate these as well as other points. The more I have seen of plethoric palpitation, the more obvious has become its importance in connection with diseases of the heart, for the ultimate effects of such forms of palpitation do not always stop at mere palpitation. Dr. Parry ascribes to undue accumulations of blood, those anomalous affections of the heart which resemble angina pectoris. "Pain in the chest, more especially in the left side, stretching into various parts of the left arm, is common to all diseases in which blood is unduly accumulated in the cavities of the heart; and if, during the peroxyem, this motion of the heart is excessive, bot to force and frequency, producing what is commonly called 'palpitation;' that circumstance shows the disordered state to be of a different kind from that which constitutes angina pectoris.

Pathologists baving seen angina (which above all other affections exhibits the tendency of the heart to spasmodic action) prove fatal without any organic lesion whatso-ever, have decided that these changes are not the real cause. Indeed, we see preparations enough of ossifications and oth structural changes, in museums of morb anatomy, which were not only not fatal, but not indicated by symptoms during life. Professor Macartney thinks that no man has ever died yet of organic disease of the heart alone, but from morals action super-vening on morbid strictions the by ossification does not occur till the heart is excited, and morbid action added. No part he observes, is so liable to be affect through the medium of the nervous syst by the mind, or the stomach, which throws light on the success of Mr. Abernethe practice. (Notes of Pathological Course, by J. F.)

With these impressions, some pathologic with these impressions, some pathologisms and con-trol light hart, and large down a system regard even angina to high frequently the state which belongs to that consum-satisfied the large to that consum-satisfied the large to the consum-satisfied to the consum-batisfied to the consum-tion of blood in the large vessels; " so, in the words of

611 DR. FOSBEORU ON PLETHORIC AND SUMPROMATIC PALITATIONS.

Dr. Forbes, who coincides with Dr. H., "a in the larged the presentation were often congested state of the heart and large questions in interminates in the pulse. By vessels." Even Dr. Parry, in tracing out the Armshing says he had seen several in vessels," Even Dr. Parry, in tracing out the causes and characters of angina pectoris, in a first-gate specimen of strong reasoning and critical powers, did not attribute the disease entirely to the effects of ossification of the coronary arteries, for he distinctly states that the symptoms show that accumulations of blood about the heart and large

vessels, take place (Dr. Macratosh).

11. Plethoric palpitations may be known more or less by these circumstances:—

1. They are excited or increased by every kind of motion or exertion, especially by lifting the arms and exerting the chest, by ascending stairs and acclivities, and doing whatenever hurries the blood through the heart and lungs.

2. They are increased by cold, moist, and foggy weather, or whatever produces chill of the body, and so forces the circulation from the exterior to the interior vesuels of

the body.

3. They are more persistent than nervous palpitations, and occur by day as well as by

night.

4. They are often accompanied by pain and weight of the arms, and particularly of the left arm.

5. They are sometimes attended with throbbing and fulness of the vessels of the head and neck, and pressure about the throat and ears, particularly in going up ascents.

III. The third kind of palpitations, or symptomatic, are said to be of a more temporary nature than the nervous or plethoric (Professor Graham). They originate from the participation of the heart in the affections of every other organ, and exhibit the morbid influences to which it is obedient under undue excitement (Dr. Blundell; They accompany-

1. Pericarditis, in which both the pulpitation and dyspacea merely indicate sympathetic irritation of the heart (M. Andrai .

2. Adhesion of the Pericardium. Mr. Huuter was of opinion, that when adhesions take place between the pericardium and heart, the patient generally recovers, but is troubled with a palpitation, irregular pulse, oppressive breathing, faintings, debility; and the name of angina is generally affixed to these symptoms; but if the inflammation of the pericardium approach to the suppurative rocess, it produces death. (Mr. Hunter, MS. Notes of Lectures, by T. Creaver, M.D.) Mr. Henry Cline, who paid much calm and patient attention to diseases of the heart and circulation, also thought that fluttering, from the frequency of the pulsations or contractions of the heart, with intermission of the heart's action, denoted inflammation of the pericurdium, and adhesion of it to the heart. (MS. Notes of Lectures, by J. F.)

Armshing mys he had seen several is stanced as such adhesions without inter topi and thinks that Dr. Balli mitte mistakesi in Neither at athem specialsometer right or altogether right or altogether misses symptom is equivous, and increase affections of the heads, and increase existence of such a characteristic of such a characteristic statement of such as such the the

CASES AND ARGUMENTS

ADDUCED TO PROVE THAT " GONORANCEAL RHEUMATISM" 18

COPAIBAL RHEUMATISM.

To the Editor of THE LANCET.

Sin .- I should feel obliged by the insertion of the enclosed remarks in your excellent Journal. I am, Sir, your obedient servant.

FRANCIS EAGLE.

29, Poultry, Jan. 12, 1836.

CASE I.—May I, 1834. I was sent for to visit Mr. C. H., who was labouring under a severe attack of rheumatism in the left leg. There is tenderness at two points onlynamely, at the anterior superior spinous process of the ilium, and along the dorsum of the foot. He gave the following history of his complaint : -

About two months since, having contracted a generrhora, a friend prescribed for him a mixture of cubebs and copaiba, which he took for rather more than a week, when he experienced a severe attack of pain similar to the present. He discontinued the copaiba, and, with the aid of warm clothing and mild aperient medicine, got rid of the pain in a few days, and again had recourse to his copaiba mixture, when, on the tollowing day, having a return of pain, he suspected that the copaiba had, to use his awn expression, "something to do with it." He now left it off for a week, and the pain subsided as before, but on again taking bubsided as before, but on again taking posiba mixture, the pain for a third of the gamection of the copains with piper remedies for the gonorrhun corted to them with partial benefit bramme weeks. Being bowever, very h annoyed at the long continuance of disease, he consulted an eminent surthe at the same time stating his objection.

The treatment now adopted consisted in the local application of leeches, and the administration of mild aperients to improve the chylopoletic viscers, and although the pain had affected the parts for some weeks, more or less, my patient was perfectly well in sixteen days, and up to the present date has experienced no return.

Case 2.- A young man, aged 27, messenger in a fire-office, whose habits of life were far from absternious, perceived, on the morning following a debauch, a discharge of yellowish matter from the arethra, and immediately applied to a surgeon for advice. A copaiba mixture was prescribed for him, of which he took a dose three times a day. On the second day, however, all discharge having vanished, he discontinued its use, and went to bed rather unwell. During the night he awoke with considerable pain immediately under the left scapula, and on the following morning applied to me, when I at once advised the application of twelve leeches to the part affected, to be followed by a warm bread-and-water poultice, at the same time directing my attention to the state of the stomach and bowels, which were out of order, and in five days he returned to his office.

Kemarks.- The belief that the rhoums. tism arising during a gonorrhora is a spccific disease, requiring a specific remedy, is, if I mistake not, founded upon a very shallow foundation-1st, that because it arises during generahers, it is generahers!; 2ndly,

that it is curable only by mercury.

At page 210 of Dr. Titley's work on "Discases of the Genitals," speaking of this discase, he says, " That this form of disease sometimes, though rarely, occurs during the continuance of a generative. The pain and swelling are more especially confisce to the knees and ankles, though, in some instances, the symptoms are more diffus the pain is more acute, and the general disturbrace of the system more violent. It is usually not until gonorrheen is on the decline that these symptoms supervene, though, accasionally, they have appeared to follow a sudden cessation of the discharge produced by the use of cubels or copalia. There is often much puffiness and tenderness of the ankles, especially towards evening. The skin is not externally red, and the pain is not much increased on pressure; the pulse is quickened, the stomach becomes disorlored, and the appetite declines, or alto-gether falls. Occasionally it happens that Starruled, and a compound considerall these symptoms are suddenly relieved by

an eruption of papulas, in clusters, or, some-times, of puscules, in very minute patches.

When these appear, not only are the pains
When these appear, not only are the pains
Telieved, but the constitutional symptoms
also yield; and the cruption, after some
almost immediately subsides. days, though sometimes not for many weeks, grows paler, and a desquamation anceceds, matter by Hunter or Abstract leaving a slightly discoloured state of the not adopt the copsiba system? skin, which gradually subsides.

It is a fact worthy of considerable attention, that two of the most careful observers of disease, Mr. Hunter and Mr. Abernethy, but especially the former, who devoted much extremely rare. time to the study of the venereal disease, in all its forms, should have made little or no mention of gonorrheal rheumatism. This fact appears in a still more striking point of view, when we consider that they scarcely ever, if ever, adopted the copaibal method of healing the disease; while Sir Astley Cooper, Dr. Titley, and others, stanch advocates of the copaiba system, have devoted considerable space to its nature and treat-

The preceding extract from Dr. Titley's work, is an accurate description of what may fairly be called "copaibal fever," followed, as it so often is, by an eruption peculiar to that medicine, and by no means confined to its administration during a gonorrheea. The circumstance of this form of rheumatism occurring during a gonorrhoen is, it is true, a coincidence, and may that it arises very frequently where no coevidence), it is fair to doubt its existence as gonorrhoal rheumatism.

Copaiba produces derangement of the intestinal canal, fever, and cutaneous eruptions. All this it does commonly, whereas gonorrhea not once in a thousand cases

produces either of those effects.

But even admitting that this form of rheumatism is a consequence of genorrhoa, what explanation can be given of its production? Does it arise from sympathy? Or does it arise from specific venereal irrita-tion, which its curability only by mercary would seem to imply? And if so, why is it not followed by secondary symptoms?

I assume the position, then, that the rheumatism occurring during a gonorrhea, is, in very many instances, a production of the remedy, and not of the disease; that it is "copsibal," and not "gonorrhoal" rheumation, upon the following grounds :-

1. Upon the preceding cases, and their

daily occurrence. Upon the fact that it arises during the

administration of copaiba in other diseases. 3. That while it is proved that copalba produces intertinal derangement, fever, and quences of genorrhess, in the abstract, are extremely rare. cutaneous eruption, commonly, such conse-

PREDING, IN A HORSE, AFTER

LOSS OF THE ENTIRE TONGUE.

Related by M. CALLEUX, in the Memoirs of the Veterinory Society of Calvados.

A HORRE, belonging to the 4th regiment of Hussars, was very difficult to groom, so the soldier who had to manage him, fixed in his month a strong chain of iron, deeply serrated. Another man held the ends of the chain, and giving it a terrible jerk whenever the horse was rebellious, sawed off the tongue completely at its base, and it fell to the ground. Much hemorrhage did not follow. The portion of tongue detached was be nothing more; for, unless it he proved four inches and a half in length, and the disunion was effected at the frænum, or pulha is administered (against the opposing precisely at the point which separates the base of the tongue from the free portion of it. My first thought was to destroy the animal; but the interest which every one took in him, on account of his power, and his docility in every respect, except when he was groomed, and the desire to ascertain how he would feed himself when the useful part of the tongue was taken away, couraged me to endeavour to save his life. Having stopped the bleeding, I kept his mouth constantly open with a gag, which I could extend or contract at pleasure; and I frequently injected cold barley-water, sugared and honied, and deprived the animal of every kind of food. On the tyred day I thought the wound sufficiently farburable to allow him a little harley-meal and water. He plunged his head into the ! half way up to the eyes, and then by i of the strongest inspirations, and es up a very little at a time, he country empty the venet. I then made this, fail of paste, of bran and barley-meal? I tacked it with avidity, select a per pit it between his lips, and seemed astoriith that he could do no more with it. I then fore renounced for a while this mode feeding him, and contented myself v rendering his harley-water more nout by increasing the quantity of the me stirring the mass well while he was de

flag it. In this manner he was fed during three or four days; at the depiration of which period the would was bested.

It have presented him afresh with the kind-by fresh which I had before made, and I remarked that he set binnell to work more gently in ander to eat it. He kept his head constantly is the manger, and, having eathered between his lies a wall nortice of gathered between his lips a small portion of the fond, he pressed it against the bottom of the manger to as to force a part of it into his mouth. He then gathered another portion, and, subjecting that to the same kind of pressure, the first pellet was forced somewhat further backwards; and so he continued, until, bit by bit, it was pushed on to the back part of the mouth, and swallowed. This was the work of a long time, and proceeded very slowly, but by degrees he was able to dispose of the whole of his feed. During the time of his repast he was in a profuse perspiration, showing the difficulty which he found in satisfying his appetite.

This continued during three months, when it occurred to me to mingle a few grains of oats with his barley-meal and bran. At first the oats were swallowed without being masticated; but, by degrees, mustication returned. At length he began to eat with less difficulty, and the profuse sweat with which he used to be covered, disappeared.

This kind of food, convenient enough for a horse that does no work, did not accomplish our purpose: we wished to restore him again to the ranks, and to fit him for that, it was necessary that he should have more substantial food. I gave him some hay, at first in small quantities at a time. He took it in the same manner that he had been accustomed to manage his mash; he gathered it together with his lips, and formed it into a kind of pellet with his lips, and then pressing it against the hottom of his manger, he gradually forced it sufficiently far into his mouth to be enabled to seize it with his grinders, a new pellet constantly pushing on those that were before. It was fifteen or twenty days before he could mayage this cleverly; and then, being kept apart from the other horses, he was able to manage the whole of his ration. Oats were, as he ore, mingled with his mash, and their as agore, minged with his mash, and their distinct by was gradually increased, while the lay has proportionably diminished, until he lay has proportionably diminished, until he late the same time, and is the same time, and is the same of the chart, he could not manage to the late the late that he could not manage to the late that he could not manage that the late that he could not manage that the late that he could not manage that the late that th no. it. As to chaff, he could not manage sion returned, he now does his duty as before, and is in perfect health. A similar the so this I do not recollect to have seen. not expect to succeed at all; but its mate result induces me to publish a which. I think, will be interesting to professional brethren. - Veterin Jes.

JERVIS-STREET HOSPITAL DUBLIN.

A 1681 . 8 Av. 5

TREATMENT OF PRACTURES OF THE LEG AND THIGH BONES OF CRIEDERY WIFE. OUT SPLINTS.

Tax following remarks were made by Dr. WALLACE, on going through the above hospital, on Thursday, January 7] :-

This case of fractured thigh, gentlemen (in a boy fourteen or fifteen years of age), is worth your attention. The fracture exists where the upper joins the middle third. I shall treat it without splints. It has been my practice to treat fractures in the legs and thighs of children for more than ten years without splints, and I have never had occasion to regret the plan. Deformity never, I may say, occurs, and even when it does, a very few weeks see it removed. When I commenced this plan, some of the routinists cried out, "Oh, what a shame to neglect the patient in such a manner!" They little knew the object in view. I do not believe, however, that I have ever before adopted the practice in so old a person as this. I am induced, on the present occasion to give it a trial, not only from the result of my own practice in younger cases, but from finding in a paper by Mr. RADLEY, published in THE LANCET a short time ago, that this practice has been by some persons lately applied to the fractures of adults. confess that I should be tardy, in general at least, in going so far, because, if any deformity resulted, it would not be so likely to disappear afterwards. This is the source of my opinion as to the propriety of treating fractures in growing persons without splints, while I would not treat those of older sub-jects in the same manner. See! how this boy lies. It is the manner in which children, who have got fractured thighs, always lay themselves. You see he is on the lest or fractured side, the leg bent a little on the thigh, and the thigh on the pelvis; and he lies with his abdomen half turned round to the surface of the bed, his sound lower limb being thrown to the right, and his elbow and fore-arm, of the right side, thrown on and supported by the hed. Now, he will lie in this position until he begins to feel strength in his limb, and then he will in-stinctively begin to move, and exercise is through the bed, in proportion to the strength which be acquires. I have very frequently noticed, in treating the fractures of very young children, that they allow the not hurt them, with great gentleness to their restraint, until the bone has acquired some strength, and then they begin to be weary of restraint, will not allow the handages to remain quiet, will be found constantly to faddle with them, and will thus keep them igose. In fact, if you wanted to keep a child's arm, which had been fractured, longer in thes an unfrequent consequence of diffuse splint than was necessary, you would exercely inflamenation of the forest of the fores succeed in diving so. The child, by its con-stant perseverance to remove restraint, would conquer. In treating fractures of the thighs in children without splints, I have never found that the attendant complained of any difficulty in the removal of the patient discharged.

CURE OF LUPIFORM STPRILIS (A COMPLEX FORM OF THE VENEREAL DISEASE) WITH THE HYDRIODATE OF POTASH.

Here is another case deserving your attention. It is a case of the disease which I call " lupiform syphilis." This name expresses its origin from the venereal poison. and the resemblance which it has to lupus. Its remarkable characters are, its occurring in subjects who have not only had the venercal disease, but who have taken mercury in large quantities for it, and its commencing by tubercles, which pass into ulce-ration, and form groups of holes, which, sooner or later, heal, while others are formed in their neighbourhood, or on other parts of the body. Mercury will generally day them NEW METROPOLITAN UNIVERSITY up, but they soon break out again. For this form of disease there is no medicine which acts with the same certainty as the hydriodate of potash. You have at this copy, has been presented to the Minister moment in the hospital two other cases, by the teachers of the Blenheim-Street School those of Free and Holland, which demon- of Medicine: strate the great value of this medicine in this form of complicated syphilis. I will make these cases the subject of a clinical lecture. The man whom you see before you commenced the hydriodate of potash yesterday morning. Bring me the tests, and let us examine his urine. You see how it is already loaded with the medicine. He institution would be founded upon the browcould have taken only half a drachm of the salt since yesterday. It is remarkable how soon the presence of this medicine can be detected in the urine, and how soon it escapes from the body when its use has been omitted.

CONTRACTION OF THE PINGERS AFTER DIF-PERF TERMANDATION OF THE PORE-ARM.

Look at this case. It is a case of diffused inflammation of the fingers, band, and part of the fore-arm. It has already formed matter and sloughs in the subcutaneous tisme. There were some incisions made in lafter to be established, he placed upon it yesterday, and you see with what great and equal footing under the new university advantage; observe how much better it is to-day. I fear, however, that it will not evinced by the pupils ought to be endend very satisfactorily. The patient is a with equal hosours, no matter when our very old man, and, besides, the sheath of what means acquired, and that no only the flexor muscles appears to be much en- tages ought to accrue to any parties gaged, and even, perhaps, the flexor muscles achouls or classes of teachers, exegthemselves are so; for, you may remark, all reputation derived from the man the fingers are bent towards the palm of which she pupils acquit themselves as the hand, and cannot be straightened. A examinations; unless the competency.

care should be taken to b a state of extension, and e are all healed, but have not unfreque from a neglect of soll to the hospitals and many weeks after th apparently well. You i by remar frequent diffuse inflammation is at present This, you know, is one of its characters Another of its characters consists in it either occurring in a limb without any evi dent cause, or from some very trifling cause You see this illustrated in the present case The patient says that it was caused by hi burning, in a very slight manner, the enof his thumb, by touching some hot body,a degree of injury which, probably, unde other circumstances, would have produce no other effect than a state of painful feeling for a few minutes.

A MEMORIAL, of which the following is:

" The teachers of the School of Medicine in Blenheim Street, founded by the lat-Joshua Brookes, F. R. S., have hitherto ab stained from making any representation to his Majesty's ministers respecting the projected establishment of an university is London, because they believed that the nev basis of the public good, and therefor governed by the strictest rules of justice and impartiality.

" But in consequence of the uncertaint which prevails with regard to the intention of the Government, and considering that this has given rise to rumours of an injuriou tendency, and lest their silence be construe into indifference respecting the high in terests involved in the question, they den it to be their daty most respectfully bu earnestly to request that all the schools c medicine at present recognized, and here

LYNN SELF-SUPPORTING INSTITUTION

FOR THE SICK AND HURT.

To the Editor of THE LANCET.

Sin,-In consequence of the prompt and handsome manner in which you noticed a former communication on the subject of our Institution, I am requested by the Members of the Board of Management, to transmit

the following statement of facts.

The Lyun Self-supporting Institution has now been established two years, and I am happy to add, has fully answered our most NONPAYMENT OF MEDICAL WITNESSES AT sanguine expectatious. The industrious wo king classes are delighted with it; and although it does not, perhaps, sufficiently rememerate the practitioner, vet it pays him better than parish practice. It must also be meeren that through this plan, many mpthing before. But putting aside all the toration of advantage to the profession, and to the effect spon those planes for whose benefit is was justifuted, have much reason to congratulate our-Thises on the great improvement that this I subjoins.

Method to gradually working, both in this Surely, Sir, this injustice to our profession special and physical conditions of the labour cannot longer exist. I carnotily trust that

a year small weekly payment, not only to ensure prempt and efficient aid for bimself and family, in case of sickness, or accibut it gives him the privilege of choosing his own medical attendant! It has also the happy tendency of raising the working man from a state of dependence and degra-dation, to one of independence and self-

adopted with so much benefit to the public similar Institution, I can only say that a in France, and to which the advancement of copy of our Rules and Regulations shall be medical science in that country is mainly at their service; and I confidently depend upon your powerful ald in disseminating any information which has a tendency to comthe teachers of the Blenheim-street School teract the baneful effect of the old dispenof Medicine solicit the opportunity of lay-sary system, which I verily believe has been ing before his Majesty's Ministers, in any the means of degrading, and of ultimately way that may be deemed expedient. Con- rending to the workhouse, many individuals, fulent that were it adopted in the new Uni- who, without such temptation, would have versity, they would have to congratulate the remained industrious and useful members Government on the formation of an Insti- of society. I remain, Sir, your very obe-

JOHN TWEEDALE, M.D., President of the Board of Management. Lynn, Norfolk, Jan. 9, 1836.

P.S. Permit me to avail myself of this opportunity to express my admiration of the cordial and disinterested co-operation of those general practitioners of this town, who so willingly have lent their aid in this novel undertaking, which, in the outset, presented many difficulties without any certainty of adequate remuncration.

J. T.

. Dr. Tweedale will confer a favour on the Editor by forwarding to THE LANCET OFFICE, at an early period, a copy of the rules and regulations to which Dr. T. has referred .- Ep. L.

CORONERS' INQUESTS.

To the Editor of THE LANCET.

Reading, Jan. 9, 1836.

Sir,-A short time since I attended a corouer's inquest on a poor man, to whose assistance I had been summoned as the nearest practitioner. His friends being unable to defray the charge, I applied for payment to the Board of Guardians, a copy of which application, together with their reply.

Mr. Warburton will succeed in obtaining an Among the many advantages of this In Act of Parliament in the curving session,

. . . .

securing to we a fair compensation for ettendance in similar cases. Should you sens with me in the expediency of calling the attention of the profession to this subject without delay, an early insertion will obliga Your obedient servant,

GROSSE MAY.

" To the Board of Guardiene of the Reading Union.

" Reading. Jan. 5, 1836.

"Gentlemen,-I take the liberty to remind you that some time since I made a demand of one guines for attendance on the inquest of --- Taylor, and at a subsequent personal interview was favoured with your sesurance, that the case should be reported to the Poor-law Commissioners, and that your decision would be guided by their opinion.

" I take leave to recall your attention to the subject, and should you determine to refuse my claim I hope I shall not be deemed presuspituous in requesting a statement of the Casmissioners' opinion, as you will perceive that not merely this particular claim, but the interests of the medical profession in similar cases, are involved in their decision. I have the honour to be, Gentlemen, your obedient humble servant.

"GROBGE MAY."

" To George May, Esq.

"Reading Union, Jan. 7, 1836. " Dear Sir,-I have to inform you that the Board of Guardians, in conformity with the promise they gave you, made application to the Poor-law Commissioners for instructions for their guidance in respect of the charges of medical men for attendance upon coroners' inquests, and I am directed by the Guardians to transcribe for your information the reply of the Poor-law Commissioners to that application:-

" 'The Poor-law Commissioners for England and Wales have to acknowledge the receipt of your letter of the 19th met. (December), and with reference to your inquiry upon whom it devolves to defray the demand of medical men for attendance upon coroners' inquests upon the bodies of paupers, the Commissioners desire to state that they are wholly unacquainted with any authority under which the payment of witnesses at coroners' inquests, or indeed of any other expenses attending inquests, can be charged upon the poor-rates.' I remain, dear Sir, your obedient humble servant.

"THOM G. CURTIES. "Clerk to the Board."

The members of the profession will do will to remember that their speedy perso-nal applications to Members of both Houses, of Parliament, will have a material effect, in nal applications to Members of both Houses, east apon my character. I will only beg to of Parliament, will have a material effect, in said, with respect to the other statements the approaching session, on the decisions of in that gentleman's letter, that considering the Legislature, with regard to the subjects myself merely as the medies through which discussed in the foregoing letters.—Es. L. The communications from our Association

TUNERIDGE-WELLS CONTRACT.

To the Editor of Tax Labour.

Stn. will you oblige me with an oppor-tunity of correcting a missistement in last week's Lawcaz, in which I am personally concerned, under a promise that I will not

again so trespass on year indulgence.

Mr. Sopwith in his communication to you has stated, that I called upon him (being one of the Committee) for the purpose of pressing him to attach his signature to the Resolutions of our Association, and on his refusal so to do that, I told him that the consequences would be, exclusion from medical societies, and objection on the part of medical men to render him assistance in cases of emergency.

I regret that Mr. Sopwith should have made these observations, as he was putting a false and unfair colouring upon the whole

transaction.

It is true that I called upon him with the view of obtaining his signature, from a desire that, in a matter alike interesting to all, there should be unanimity in the expression of our sentiments. It is also true, that I did represent to him (but upon his repeated request as a friend so to do) the possible consequences of his refusal to act in concert with us. But, Sir, Mr. Sopwith has omitted to tell you that in this interview I did most distinctly disclaim any authority as a member of the Committee, to communicate with him, and gave him as my motive for so doing (and for its sincerity at the time I can most truly vouch) a desire that he should avoid the unpleasant position in which, as a young man, just entering on his professional career, he must be placed by such refusal. With my conduct at the time, he appeared satisfied, and actually thanked me for the trouble I had taken. This explanation was again rendered to Mr. Sopwith at a second meeting of our Association, upon his referring (much to my surprise) to the sphiect, before the whole of my professional brethren present, to all of whom it seemed satisfactory. As to a refusal to afford him assistance in cases of emergency, th Mr. Sopwith would imply much more at that was intended to be conveyed by the was, that he could not expect, in his as from home, that courtery which is of given and received by medical men.

Having entered into this explaintion solely to remove the stigms which was so evidently intended by Mr. Sopwith to be

were made to you, I do not feel called upon the state of time and attention, equally capable of being antisfectority explained. I am, Sir, your very obedient servant.

Tunbridge Wells, Jan. 11, 1836.

DUTIES OF MASTERS AND APPRENTICES.

To the Editor .- Sir .- The letter from a " Licentiate of the Apothecaries' Company, published in the number of your interesting and valuable journal for December 12, bears on a subject of no minor importance to the many individuals who make choice of the medical profession, and it struck me on its permeal as demanding reply. I do not for one moment desire to advocate the repetition of changes in the regulations of the Apothecaries' Company, or the unnecessary length of time originally required for the actual servitude of an apprentice. The tedious routine of studies to which students are subjected also, I consider to be exceedingly unwise and harasting, and highly discreditable to the Court of Examiners, a fact which is rendered remarkably evident after reading the letter of "A Medical Pupil" in THE LANCET of December 12th. Nevertheless, whilst such a Company is upheld by Act of Parliament, it is necessary to comply with its regulations, though I trust that a day of change is not far distant. My intention now is to dissent from the opinion of your correspondent in imagining that a practitioner has any right to expect benefit from the assistance of an apprentice who has placed at the command of his instructor 200/.; and I contend that it would be contributing greatly to the good of all, if practitioners thought less of the services to be rendered by their apprentices, and attended more to furnishing them with the medical knowledge which young men are placed with them expressly to learn. The gene-rality of apprentices are compelled to undergo, in the strictest sense of the term, actual servitude, during their whole apprenactual servitude, during their whole apprenticest ip, being constantly employed at the counter, dispensing medicines for patients, whose cases they sever have an opportunity of intestigating, and the effects of many of the intestigating, and the effects of many of the medicines they never have time to taking although to learn them they have the life although to learn them they have the life and their pressures; and I cannot be approached the propriety of the counterful from them that "assistance" which should be obtained through the medicine of carolifed assistance. Having thus arisressed qualified assistants. Having thus expressed my thoughts on a very important subject, T remain, Sir, your obedient servant,

A GENERAL PRACTITIONER. Disimber, 1835.

Transm.

To the Bill'to Min.—At a time so from which departance to the profession as a process, when a new, and, let us hope, improved system, is to be introduc stay be desirable to state even individual instances of grievances which have been inflicted under the old system. I mention one which is mine, and probably is that of many other students also. When I first entered the profession, being totally ignorant of its regulations, and thinking that a know-ledge of medicine was the only real object to be sought, I was apprenticed to a practipolis, who, at the expiration of the first four years, I had the mortification to find, had not obtained the license of Apothe-caries' Hall. I was then rearticled to a licentiate, but owing to this delay I had not commenced my hospital studies previous to the late regulations coming into effect, and (having but limited means) am materially obecked in my advancement in the profe sion, the arrangements of the apprentice and certificate system have placed a veto of many years on my position as a candidate for professional honours and emoluments: 1 am, Sir, your obedient servant,

J. V. S.

HONESTY TO PURCHABERS OF FIRST Epitions .- To the Editor .- Sir, - When first I saw Dr. Mackenzie's work on the diseases of the eye I was induced to pur-chase it, and I look upon it as an excellent and elaborate treatise; but I see a second edition announced, with plates, &c. New. Sir, those plates must be a valuable acquisition to the new volume. I trust, therefore, that in common honesty to the purchasers of the first edition, the plates will be enabled to be procured by them, in the form of an appendix. Waiting to know whether we shall have to thank Dr. Mackenzie for this measure of liberality, so rare amongst authors -certainly never observed by bookmakers - 1 am. Sir, your obedient servant, A Poor Madical Bookworm.

Dorset, Dec. 1835.

Ma. DEWHUBST .- To the Editor of THE LANCET.-SIR,-I perceive another attack made upon me in your journal of this day, and shall feel obliged by your inserting this reply as early as convenient, particularly as it has been done by a malevelent individual it has been done by a measurement the fittle of to injure me. I never assumed the fittle of Fellow of the Royal Society; I know my-self better than to assume honours never a single conferred on me. I never wrote a single article in the Admentional Magazina, but the the Education Japane I added to my name

error was immediately corrected in the se sequent numbers by me; and I need not form you that typographical errors for quently occur in the most eminent print offices. I am not aware, Sir, that it is crime to ask a noblemen or gentlemen to urchase my work, for the benefit of my infant family; although I am well acqueinted with the individual who, under the assumed signature of M.R.C.S., has imposed upon you to insert the letter in question, as by an interview I could easily demonstrate. Had not misfortunes from a severe illness of two ears from a dissection wound plunged me into difficulties, I should not have had to solicit subscribers. Had I been able to pay the fees, I long ago should most probably have been elected F.R.S.; and in consequence of my inability, Earl Stanbope three years ago generously presented me with a ticket, conferring on me all the privileges of a member of the Medico-Botanical Society; and similar bonours have been conferred on me by many London, Dublin, and provincial learned societies. That I have founded a philosophical society I admit, and I can see no reason why my poverty should destroy my claims to the office of president, which I am proud to say I have held for two years with the approbation of the members (now about 320 in London and the country), and any time you choose to attend yourself, I shall be happy to transmit the necessary ticket of admission for that purpose. As to the latter part of the "M.R.C.S.'s" letter, I have already alluded to it in my letters inserted last summer in THE LANCEY, so I shall not again refer to it. I remain, yours respectfully,

H. W. DEWHURST.

January 11, 1836.

WESTMINSTER MEDICAL SOCIETY. Saturday, Jan. 9, 1836.

Mr. RICHARD QUAIN in the Chair.

Dr. Approon, in the absence of more important medical news, related the case of a child, aged 11 years, in whose case he had committed an error of diagnosis (at Guy's?) The disease, as he had been informed by the surgeen who had sent the case, was one of amourosis, dependent on a hydrocephalic affection. He was proceeding to prescribe secordingly, when one of his pupils put his er to the chest, and detected mischief re patient was " pigeon-breasted"), and left side of the chest progoneran was sected, accompanied by a missions rattle, matter was to be facual in any work a of a very peculiar kind, indicative of sellen- aulifect, prior to the appearance

9. 空。

for of whereles, and he (Dr. A.) concluded, the content of the con faith or sixth rib, which added to the Her-plexity and interest of the case, and not feeling satisfied, by (Dr. A.) visited the boy at Rackney. If the treatment pursued, in spite, as he dought, of the disorganized condition of the lungs, the patient improved, but in an after examination he detected the source of fallacy. The boy was labouring under emphyseins of the lungs, and when the pneumonia no longer existed the humidity disappeared, which had led him into error. He related the case, because we were bound in duty to narrate the truth in all instances This would have been a very admirable case to have fallen into the hands of an empiric, who, if it had got well, would not have failed to blazon it abroad as the cure of a confirmed case of phthisis, so pronounced by the faculty. The case also showed the necessity of being exceedingly cautious in forming a diagnosis in diseases of the chest. The treatment consisted of moderate depletion, a mild course of mercury, paying attention to the howels, and employing blisters, which occupied about a month. For the affection of the head he had been cupped. Mercury was still employed mildly, and the sight was fast improving.

Dr. LEONARD STEWART believed that if permanent benefit were derived in the short space of a month, whatever treatment was employed, we were justified in considering it not to be a case of phthisis.

Dr. Appraon said that had the sound existed at the apex, instead of at the base of the lung, he would have pronounced it. without hesitation, the result of disorganization. Dr. A. then briefly detailed two other cases, occupants of the same bed, one the subject of paeumonia, and the other presenting pacumonia coupled with severe bronchitis, which bore on the question that was argued here some evenings back, when he (Dr. A.) maintained that in genuine pneumonia, little or no cough, and no oxpecteration, except it were blood, was pre-sent, and if a slight glairy mucus were secreted, it was from the misuse extremetion of the bronchial tubes, and it was from these symptoms being considered es to pneumonia, that the disease w quently passed by unobserved.

Dr. CHOWNE said that so long as inflammation of the parenchyma of 4 no expectoration was poured out, the disease extended to the bronchial a then there was expectoration. Ha (Dr. A) contrary, a very ancient one. Dr. Appenon mid that no correct is

hec's and Cullen, shound ors prior to Lacennec, his writing a mass of confusion of But Lacender the district of the state did us to detect the di emob certainty as our h we mig t meet a emplications which we ne limble to puzzle us.

Mr. Franching related these wherein a physician, of no mean reputation, committed the following mistake. A steet man, of full Mr. PERNANDER related limbit, from early life and suffered from enlargement of the heart: for three months he was troubled with a constant cough, with slight expectoration. About a month back, as the respiration became very difficult and frequent, the physician was consulted and used the stethoscope, but he found some difficulty in explaining the nature of the malady. No respiration was to be heard over any point of the chest, nor any pecu-liar sound in the region of the heart; the expectoration was of a thick mucous character; the blood drawn was buffy. The diagnosis given by the physician was, that the patient suffered from acute bronchitis, and an effusion of fluid within the chest. Shortly after this examination a faintness came on, which was relieved by brandy, but at the expiration of a week a second returned and the man died. On inspection of the body after death, no fluid was found on either side of the chest, and the lungs looked perfectly natural, but on compressing them the contained air could not be forced out, the air-tubes being blocked up by the swelling of the lining membrane. The pericardium was highly florid and inflamed.

Some discussion ensued between Drs. Addison and Chowne, with regard to the writings of Culien, the former deprecating them, from the confusion prevailing in the parts relating to the diseases of the chest; and the latter advocating them. The subject was then dropped to make room for that of magnetism, which occupied attention for an hour beyond the usual time of adjournment; but nothing was elicited worthy of being reported, and in order to produce from the diversity of opinions something more satisfactory, it was moved by Mr. CHINNOCK and carried, that Dr. Ritchie, who was prehe requested to enter fa'ly upon the at at the next meeting, when the meetadjourned.

resident of the Royal College of ad an interview with the Chanthe Exchequer yesterday, in Downt. A deputation of short-stageproprietors had an interview a

MEDICO-BOTANICAL SOCIETY

.. CREEKVATIONS ON THE

PERUVIAN BARK.

By GRONGE G. SIGMOND, M.D.

Read at the Meeting of the Medico-Botanical Society, Jan. 12, 1836.

It appears that at about the year 1639, the attention of the ecclesiastics in Spain was drawn to the bark of certain trees. which had about seven years before been imported into that country from Peru, their newly-acquired conquest in South America. It possessed a febrifuge power, which had been successfully exhibited upon a member of their own body residing at Alcala. It had likewise acquired some degree of reputation. amongst their own countrymen in the new world. The Jesuits, a powerful, active, and highly-intelligent order, who aimed to be the depositaries of the knowledge of the ag in which they flourished, exerted all the influence over the Christian world, to diffus under difficulties of no ordinary kind, this important drug. Many failures, however, from an ignorance of the proper mode in which it was to be employed, and from the importation of varieties possessing little or no power, awoke feelings of the stronger prejudice against it. Several years classes during which a severe war of words we waged, before it was universally acknow ledged to be what Dr. Robertson, the historian of South America, has justly de-scribed it, " the most salutary, simple, and perhaps the most restorative virtue, that Providence, in compassion to human infirmitie has made known unto man." A beautiful tract, in our own language, from the classic pen of Sir George Baker, gives us a most interesting history of the first introduction of the Peruvian or Jesuit's bark into civilized Europe, and more especially into this country, and the numberiess works that have been published on that subject are founded upon this every. But many other points of very great importance have be discussed, and still remain for elucidati for, although many inquiries have been stituted, and individuals of high sole attainments have been engaged in vario researches, who have, with dilig discrimination, employed thems citing facts, we have yet much to lear much that is unknown, to disc years since, Heisrich von Bere work in Gorman, "An Att a Monograph of the Barks," in wh proprinters had an interview little are a list of no less than 6.72 annihous une right hom, greatenan immediately had written upon the subject, and of 300 hooks and pumphlets that had been and hooks, and this did not contain some of the

immediately within the scope of the inquiries of this institution, and which demand our attention. The first question to be discussed is, What are the trees which furnish the genuine cinchona, and how are they to be distinguished? The second is, In what way are the medicinal virtues which reside in these trees to be best obtained, for its administration in the great variety of discases in which it has been successfully

employed?
The first or botanical question, although it has been so much sgittled, still remains in some degree of uncertainty; we appear now to be much nearer its solution than we yet have been. Amongst those from whose labours we have benefited, are some of the nost distinguished men, De la Condamine, Joseph Jussieu, Mutis, De Candolle, Richard, Zes, Rues, Lambert, Laubert, Humboldt, Bonpland, Viry, Pèe, and "though last not least," Don. The second or the pharmacontical question has also a long train of illustrious men to boast of. Pelletier, Caventon, Batka of Prague, Brera, Martius, Pfaff, Brandes, and I have on this occasion to point out the labours of our own chemist, Battley, which may be fairly considered as mong the most important that have yet been undertaken.

It was in the year 1738 that the celebrated French mathematician De la Condamine, who, was then resident in Peru, gave the first botanical description of the Peruvian Bark; but his wish to import it into Europe, either by seeds, or by cutting, was unsuc-cessful. The high estimation in which his efforts were held, is marked by the name which was by the universal consent of the he described, and the Cinchons Condamines was admitted in the Pharmacoporis. In Germany it was called "Der Offizinelle Fieberrindenbaum; in France, LeQuinquina; in Italy, China Chinachina; in Spain, Corteza de Loja; in Portugal, Quina; in Holland, Kineboom; in England, the Peruvian Barktree; in Denmark, the Quinatree; in Sweden, the Quinatred; and all the varieties of the bank found in commerce were imlicitly believed to be the products of the tree thus described; different engravings of it have been given by Flenk, by Humboldt, a translation of the papers of Has bille. (and Hospiand; the one which is now before I flat interesting work,—accompanies cyclic you, is from Ness Von Essenbach. Joseph collection which, through the liberality of sinasieu, who was in South America from the life. Lambert, and his well-known love of year 1739 multi 1771, gave much attention selvinos, is knowledge to the barks, but seems not much to have tused history—may be said to huse leviled fathers have been at all handled. This paper remarkable (as Noctor Manuel de country yet been at all handled. This pavels

most distinguished authors of Spain—viz. Steeperis, the biographer of Mutis, observes)
Masdevälls, Franseri, Lopez, Banares, and the the commencement of a botanic da. since that time the discoveries which che Mutis, disembarked at Carthagens, and mistry has made must have swollen the catalogue to an immense extent.

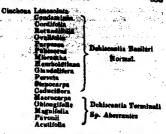

Of the subjects which have been treated, there are two questions which come more which has heatowed upon the rate of the man. innumerable sources of comfort, an pects of future benefits.

Although Penelle, Plumier, and Lossing, had made some slight botanical researches, they had done nothing for the science, which they only occasionally cultivated it remained for Jose Celestino, first to unfold the beau-tiful volume of the torks of nature which lay before him, to these the richest page for his sxamination, and to give to mankind the valuable result of his studies. He may be said to have laid the foundation for a superstructure which has now arisen, and which remains to be improved by an ardent host of labourers anxious to follow footsteps, so clearly, so usefully, so justly defined. He quickly transmitted to Europe whatever information he could glean, collections, drawings, specimens, were forwarded by him to Linnseus, and to all the scientific institutions of Europe; and the epithets which were bestowed upon him, and the testimonies of approbation and of admiration which blowed him to the grave, are proofs that talents were appreciated, and that his claims were universally recognised. He first described the four species of bark, and gave a classification in concordance with the views of botany then entertained, and the boundaries of that science are now much enlarged, and therefore more accurate knowledge of the objects of nature has been attained. Still his name is venerated as the first correct observer and the best describer of what he saw. His pupil Zea followed in the path in which his preceptor had gone, and has also a claim to our respect and gratitude, as have also Ruez and Pavon, whose rich and valuable collection of dried botanists of Europe given to the tree which specimens of the genus cinchons is now in the possession of that ardent and zealous lover of science Mr. Lambert, one of the vice-presidents of the Linnman Society; to this collection has also been added that of Dr. Thomson, which was obtained by the capture of a Spanish privateer, which was carrying home specimens collected mean Loza and Santa Fe. Mr. Lambers published "A Description of the Genta Cincolona," together with a plate, while with a plate, while when the colonary together with a plate, while when the colonary to the colo matter it contained, as from its giving to us

of Humboldt and Bestpland are next to be abled to their inquiries, and their finestictions of different species of this finestictions of different species of this finestical all bestplates as the foundation of the different, olampications which have been attentional paid more regular and more namreal fire-gramma have been followed, than the artificial ones which were so long ad-

The example of inquiry set by these botanists has been followed by other naturailists, but as the opportunities for conducting any inquiries are the very frequent, we must not expect the we are yet fully must not expect the are yet fully acquainted with the trees of the family einchona, particularly as many trees possess in various degrees the power of depositing in their bark, secretions which possess the medicinal virtues which so remarkably reside in that which is called, as superior to all others, the bark. The modern genus cinchona is limited to about sixteen species; some which were formerly included are found very different in structure, and also in their properties. Amongst these are the different species of the exostema, the losmibuena, &c.; these various families belong to a very extensive natural order, the rubracere, which possess families of great diversity of form and structure, as well as others which do not offer such striking marks by wi they may be distinguished one from the other. In the last volume of the Linnean Transactions, is a paper, very short, but most valuable, which has thrown a new light upon the subject, and has furnished us with a key, whose application has unlocked an unexpected store, from which a guide through our difficulties is obtained. It is to Mr. Don we are indebted for a discovery of no small importance to us, and which adds a further claim to the consideration he already enjoys amongst naturalists. I am happy to learn that such a successor is appointed to our late lamented friend Gilbert Burnett, in the King's College ; such a selection will be a source of gratification to every lover of that science which he has cultivated and adorned.

Mr. Dos has taken the variations of the estivation, or the measurer in which the seal smeslopes are arranged before they as the character by which the state of the groupe may be distinguished; and as these variations of estivation are found consisted with other differences in structure, is affird a very valuable distinction. The has phearwed, that in the true cinchones, of make he gives by species, the antivation is well to

In commerce four important varieties of bark are found, which are again subdivided. as I shall hereafter have occasion to show you. 1. The Quina Naranjada, or orangeyellow back, of which there seem to be two sorts; the calasays, and the royal yellow quinquina; the first title, however, appears to be given by the native Peruvines to the superior bark, which they believe the yellow to be. 2. The quinz ross, or red bark. 3. The quina amarilla, or pale yellow bark, of which there are different sorts, named from the appearance of the epidermis. 4. The quina blancs, or white bark. The opinion has been adopted by various medical authorities, and the Pharmacopœias have also canotioned it, that these different sorts of bark are the products of trees easily to be distinguished one from the other, and the Royal College of Physicians, taking Zea as their guide, have admitted three species—the cordifolio cortex, the lancifolize cortex, the oblongicolize cortex. Whilst Dr. Thomson in the London Pharmacopenia, following the authority of Mutis and Zea, considers the cortex cordifolia to be the pale bark, in Ediaburgh College, "Dr. Dubcan, and Dr. Powel, regard this as the species yielding yellow bark." Whilst the lancifolise cortex is considered by the former authorities to be the yellow bark, those whose opinion I have just alluded to regard it as that which furnishes the pale. The cinchons oblingifolia cartes, and the magnifolia, seem to be acknowledged as those from which the red is obtained. Drawings from these trees are placed before you. A list of the best engravings you will find in the work of Nees Von Essenbach. These discrepancies of opinion were unavoidable, from limited knowledge we posses innited knowledge we possessed of trees; but we have now ascertained that: shape of the leaves cannot serve as gre to the peeler, and his practical experi must remain as his only as science has made some farther at at present he depends upon his e the taste of the bark. Humbole must be allowed to be quite declare says, " I hardly know any one the va more in the shape of its leaves then clin Whoever determines single speci

dried collections, and has no opportunity to of information has been sought, and some examine or observe think, in their pative expectations raised, which I think council forests, will be led as discover different be borne out, namely, that by the lichens, species, by leaves which are of one told the or mosses, we can distinguish the tree, same branch. The yellow large, we have they have been studied with a preison orthy found at one and as the same little with a redour by botanists. Fee, more particularly. foliis ovato-oblongis, ovato-lanceolatis, and ovato-cordatis; Mutis calls it cordifolis, because it is the only kind on which cordate leaves are sometimes found. Even the laurel-leaved cinchons condamines, the finest bark, from Uritusings, has very diwhich it grows, and which equals that of St. Gothard or Mount Ætna." Humboldt very properly points out the form of the flower as the diagnostic mark, but this of course is only useful at one particular season. Humboldt also took with printer's ink, impressions of the leaves, at Gonzanoma near Loxa, which still further corroborated his opinion that the distinction made from ape of the leaves is unsafe.

I do not think that enough of facts have yet been accumulated, to enable us to judge of the value of the lichens, as a diagmostic mark of the species, but certainly their presence or absence may be considered as most useful indicators of the state of the bark. We know that the several species of the family rhizomorphs, are very active agents in decorticating dead trees; and, as has been observed, "they assist in the disintegration of lifeless organic bodies, which would otherwise encumber the surface of the earth, and be exceeding tedious in their

remo "al." Thus the rhizomorpha cinchonarum is a rare species, but whenever it exists upon the epidermis, it indicates that the bark is in a state of decay, and that it has lost its febri-fuge power. Fèe states, that the presence of himantia cinchonarum is a certain proof that putrefaction has very far advanced. The hypochnis rubro-cinesus and nigrocinctus rarely grow in great quantities on healthy trees; and the opegraphs rizicols, and fissurina, likewise may be considered as indicators of the advanced age and impoverished state of the tree on which they are found.

When I have, at our next meeting, an opportunity of resuming this subject, I shall take up the pharmaceutical inquiries, more particularly those to which I have referred as entered upon by Mr. Battley, as he has with great labour, gone through a series of most interesting experiments in his labora-

that we cannot, then, look to the varia-tion of the shape of the leaf, which must be on of the tree, whether sarrounded be exhere or standing alone, by many circ the examinations at a shink must be edmitted. Another source ments are conducted a

ardour by botanists. Fee, more particularly, has devoted great attention to this subject; in has devoted great attention to sum suppose; in his memoir on the cryptoguistic epithytes of the officinal bark, he has suppose; some singular observations. He states like the gasticurate is found, exclusively, as the yel-low bark; that she graphic inturrupts is versified leaves, according to the altitude at found only on the bark of the lancifolia; these are the lichens which you find upon the specimens before you; and, after very careful examination of a vast variety of the different specimens of barks imported into this country, they are the only ones which I have been enabled clearly to distinguish. The ascidium cinchonarum, which is said to be found indiscriminately on them all, I have never observed, at least, taking the engraving given by our late professor, Gilbert Burnett, as my guide. Upon the red bark I have never observed the slightest appearance of adhering lichen; but this study is pursued under great disadvantages, from the want of a sufficient number of engravings to consult.

THE LANCET.

London, Saturday, January 16, 1836.

THE rejection, on Thursday sennight. at Apothecarics' Hall, of a student, who was a member of the Medical School in Aldersgate-street, has created a very strong sensation in several of the "recognised" establishments; because it was well known, not only to the lecturer, but also to the Aldersonte-street class generally, that he was fully capable of executing the duties of a medical practitioner in every department of his profession. The conduct of the examiner on the occasion in question was, we understand, that of a valgar, rade, and unfeeling man, and the extent ignorance was fully proved by the s committed in his insolent attempts by altitude, by age, by climate, by rect the individual who was subjected course and heartless sp

gively the same length of time will they this foul attempt has been made to injure. continue to be made the instruments of oppression and injustice. The rejected candideta had been the apprentice of a gentleman whe was not " in favour" at the Hall, and the aswardly expedient was resorted to of making an unoffending person suffer for the supposed misdeeds of another. On very many occasions similar brutality of conduct has been shown towards the students at the College of Surgeons; and the public may be assured, that whenever so much grossness of behaviour is manifested by men who are called upon to execute public luties, there must exist in those men a narked deficiency of the very qualifications which would best fit them for executing the luties of their office. The ignorant examiner, n fact, often subdues his victim by his insoence and his memacing bearing. Not five mestions are asked before the student feels hat he is to be disgraced. This distressing ppreheusion disturbs the operations of his nemory, distracts his mind, and altogether enders the judgment incompetent for the erformance of the task which he is require d to undergo, and the unleeling wretches the thus trifle with the feelings of the capidate, behold in the mischief they create he chief source of their own enjoyment, as hey refer to the incompetency of the staent, as furnishing the best proof of their wn tact, skill, and dexterity, in conducting se examination. Most sincerely do we hope nat another session of Parliament will not e allowed to transpire without bringing into ristence a statute which shall have for its biect the institution of a PACULTY or ME-ICINE in this metropolis, wherein all the caminations shall be conducted in public, the system of concours, or professional The tyranny of "Rhubert ally anuscaches the hour of its ter-

The HAGS of the HARL will, on reading it. be ready, we subject, to plunge headlong into one of their own caldrons. The original of this letter has, we are informed. been transmitted to the examiners at t Hall.

" To the Court or Examiners of Apothecarics' Hall, London.

"GENTLEMEN,-Having applied to you last night for the license of your Company, and having been examined by one of the members of the Court, and "rejected." I must attribute such "rejection" to the operation of some private feeling, which I have good grounds for supposing existed in the mind of my examiner. In order, therefore, to prove to THE PROPESSION, generally, and to THE PUBLIC, that such " rejection " was not the result of incompetency on my part. I demand from you a PUBLIC EXAMINATION, to be conducted in the presence of a professional audience, and I now state to you that I am ready to undergo such an ordeal on any day, and at any hour which you may be pleased to appoint.

" I am, gentlemen, your obedient servant, " THOMAS SMITH.

" 1. Jewin-crescent. " Friday morning, 8th Jan. 1836."

MANY erropeous opinions are entertained relative to the power which can be conferred by the Crown on the governing body in granting a charter for the establishment of an University in this metropolis. Most of those opinions are equally absurd and unfounded, but there is one which operates at this moment to the disadvantage of professional and public interests. It is believed, we understand, that the new charter can bestow on the emm ners of the University an authority, in awarding diplomas and licenses, equal to that which has been bestowed on the Co of Examiners of the Apotheosius Co many by the statute of 1815. In of it is believed that the University Charter

can empower the Sanate to grant diplomer | ber of a " Royal College of Bergeons." and liberace which shall confer upon their if he be a graduate of a second or third that possessors the privilege of engaging in medical practice in England and Wales. Hence a correspondent who signs his note "OBSERVER," "cannot conceive how the "Editor of TER LANCET should be of opi-"nion that, even supposing the University " should be devoid of any great reputation. " it should still offer no inducements to " candidates to apply for the diplomas, when "the possession of those diplomas will em-" power the graduates to practise in all " branches of the profession, and would " thus enable them to escape from the ex-" tortions practised in Lincoln's-Inn-" Fields, and the degradation of resorting " to the drug Hall in the City."

With regard to the College of Surgeons. it matters not what may be the arrangements in the new University. While we are without a FACULTY OF MEDICINE, and while the public in the distant parts of the kingdom are deceived by the name of "the College," there will be adventurers who will continue to give twenty-two pounds for a really worthless document, although it is well known to every professional man, that any individual may engage in the practice of surgery, without making any such purchase. Young men think it a fine thing to be sucked to show that they are Membets of "the Royal College of Surgeons in London:" and as the generality of the community are ignorant of the obsractor of the examination at that institution, the title often carries with it some importance in the sidnet of the uninformed public. If, therefate, the University be not founded on a principle of just and enlightened liberality. Apothecaries Act of 1815 he remarked, the -If the examiners be not men of very dis- new charter could not operate to the year dispulsion and existed attainments, and if judice of the drag-dealers in Black they dernet prove their qualifications by the and if this Act were absorpted, it is midde his which they obtain their offices, the hoped that there could then be no in "will consider the title of " M.R.C.S.L." consected with medical practice left Wild aqually he valuable on that of positions. But a charact, it s "MENCAL" In short, it will be thought distingly understood, counts some the schooly as well of a man if he be a mois-

University. The new institution, therefore, cannot, in any manner, affect the la vileges which the College of Surgeons can confer on its members, because, in beint of fact, the College has none to confer. It can neither give to a man the right to practise surgery, nor take from any individual that right. It is, therefore, strictly speaking, an incorporated nonentity. The minds of the students, therefore, will not, in all probability, be influenced in the remotest degree, either in avoiding the College of Surgeons, or in applying to that institution for its diploma, by the institution of the new University.

In the case of the Anothecaries' Company, however, the bearings of this question are wholly different. In the instance of that establishment, if it he the object of the candidate to embark in the profession as a surgeon in general practice, he must obtain the license of the Apothecaries' Company. even if he should he a medical graduate of the Matropolitan University. It is on this account that our correspondent "OBERRYER." and many others, are deceived. The source of the error into which they have fallen may be found in the opinion they hold, that the powers which may be conferred by the new charter, can interfere with, or totally abrogate, the authorities which are now exercised by the Court of Examiners of the Apothecaries' Company. In order to dispel this erreneous view, it should be recollected that no pharter can destroy, or even weaken. the powers which are exercised under an Act of Parliament. Unless, therefore, the ditions of an Act of Putlin

commun law of the land. If it be constructed cannot subvert existing rights -- how far instruments and, accordingly, entirely inoperative.

The circumstances which statutes; for if it could be adversely used, transpired in the years 1799 and 1800, are with reference to the law itself, the royal admirably illustrative of the advantage of hand might, for very unworthy purposes, publicity, and the evils of secrecy, in makpush saids by degrees all our penderous tern connected with legislation. The meamong of statetos, and the will of the Krus spagers of the old Surgeons' Hall applied to in it is each cuss suitablish a tyrannical Parliament for an Act of re-incorporation. many over the legislaterial rights of Their bill was introduced, and, on its infaor of the senate. more provisions being made known, the him therefore, that the most charter, profession denounced it as with one value. actives which is suited to the splitt of Home of Lords relative to its proposed

of the measure were denounced as being last sersion of Parliament the charters of narrow-minded and iniquitous in the ex-jour municipal corporations were all detreme, and the advocates of the scheme were abashed and dismayed, and shrunk from the dirty labour which they had been called upon to execute. The bill, therefore, was kicked out of Parliament; but it met with that fate because, and only because, its odious provisions had been subjected to the scrutinizing examination of the members of the profession.

Now mark. In the following year, to what manœuvre did the old corporators resort? Why they went slyly and secretly to the King, and petitioned His Majesty for a charter of incorporation. The scheme was successful. The royal ear was abused, the members of the Privy Council were either knavish, asleep, or deluded, and the instrument was fabricated. The results have been known and felt by the surgical profession in England, during the last sixand thirty years. The charter thus cunningly obtained, was fabricated out of the identical clauses which were contained in the Bill that had been so ecorufully, so indignantly rejected by the House of Lords in the preceding year !

This is a most instructive historical lesson. Are we to be insensible to the admonitory indications of experience, and remain unmoved by the evidence of facts, the force of which any child may feel and understand? We most emphatically exhort the present liberal Ministers of the Crown, not to tarnish their reputation, or derogate from the character which they have established for open and straight-forward dealing with the public, by obtaining for the intended charter the sign-manual of the King, until the country is placed in full possession of a knowledge of its intended clauses. Assaredly it must be confessed that a system of countly intripue and secrecy, in framing laws indiced to bring the same commod which are designed to affect the most inportant interests of the community, is utterly

All res

upon it by Lord Tavanow. The principles of a representative government. In the molinhed, as the enormities to which they had given birth could no longer by endured. Those instruments of oppression had all been obtained in secret, but the acts of injustice which have been perpetrated under them, operated on the public. Could those charters have been obtained, except by some secret, some covert method? If the application for each municipal charter had been made a subject of discussion in Parliament, it is utterly impossible that the principle of selfelection could have sustained its ascendancy during so many lustres as it has done centuries. Secrecy was the source of evil on every occasion when a municipal charter was granted, and in founding an university in the metropolis of this empire, no man in his senses can believe that a liberal Ministry will plunge headlong into such a poisoned source of irremediable of mischief.

NEW METROPOLITAN UNIVERSITY.

(From an Edinburgh Correspondent.)

THERE has not been a topic of more general conversation for a length of time amongst us here than the Metropolitan University, all classes of society being interested in the well-being of our own college; for the average number of students usually amounts annually to as many as two thousand, producing, as you may suppose, a very considerable revenue, not only to the cormorants of the University, but also to the tradespeo-ple of the town. Though some of the other lecturers in the University may suffer more or less, yet it is the members of the medical reserve who are most alarmed on the present occasion, and certainly not without good cause. They have enjoyed it may be truly said, a complete monopoly in the manufacture and sale of degrees for at least a case. tary past; and one year after another have the medical professors used all the genuity to increase the price of until, like all Jews in trade, it It is not much more than twenty years ago th portant interests of the community, is utterly added twenty-five per cent. to the price of incompatible with the spirit and operations each theset, but Dr. John Thompson's

liberal additions to the curriculum gave them The anatomical teachers, as well as the a death-blow, which they are all aware they never have recovered, nor ever can. It is only to be wondered at that their monopoly has laftetless long, and that the largest and greatest metropolis in Europe has not until now competed with them, and had a University within its own precinets, without compelling its inhabitants, as well as those of all England, to repair to Scotland, not in search of knowledge, but in order to be dubbed. consider this fact, indeed, to be a monstrous momaly in the history of civilized nations. Notwithstanding the absurdity of the attempt, our Edinburgh medical professors are deternined to make a struggle to arrest the prorress of reform in medical education. Meetng after meeting has taken place among hem, and if I mistake not you will soon see me of our anti-liberals amongst you, to sow he seeds of discontent, and nurse the tree of corruption. Young Thomson is too well mown from his past services, so that a new nan will be sent to London.

Sir CHARLES BELL is not yet come, and Dr. John Thompson, who knows him of old, quaintly observed the other day, " That 'if the surgical knight does not come down 'immediately, he never will come at all." My own opinion is that he may yet give us he go-by, for it is not common, nay I doubt f it ever occurred, that a Scotch doctor who had once crossed the Tweed ever returned to his native mountains. Parritch and kail re poor fare after roast beef and plum-nulding. However, times are changed, and iir CHARLES's discomfiture at the London University College, the total failure of the Middlesex school, and the approaching revoution in Lincoln's-Inn-fields, may induce he chivalrous knight again to try his forune here.

As it is most likely that you have not aleady seen it, the inclosed copy of his letter, eccepting the chair, will amuse you, It is in excellent portraiture of the man, whose anity is so prodigious, that he never loses in opportunity of talking about " I, myself; . 1 77

* " Brook-street, 11th Dec.

"就在水空就在现金的。"。

"My LOED,-I have had the gratificaion of receiving your lordship's letter, and accept the honour which you, the magis-rates, and council, have conferred upon me. the manner in which this appointment has eon conferred, and the assurances with your lordship has accompanied the armony in our endeavour to culti-Mich science, and promote the reshedien of the University. You place me skettion; but where, most of all, experience and Jadgment are necessary. As to the irst, T trust my habits of life give you suffident werrant. For the rest, I ground my

students, have become exceedingly impa-tient, because the "inquiry" which was instituted to inquire into the conduct of Dr. CRAIGIE, our anatomical inspector, has not yet been brought to a conclusion. circumstance has heaped such odium on the public functionaries, whose duty it was to have prosecuted the investigation without delay, that a public meeting of the students is contemplated, as the coarse and insolent doings of the awl-wise "man of leather," as CRAIGIE is called, has caused an universal feeling of disgust in the schools, and has materially interrupted the teaching of practical anatomy here.

Another topic has formed the subject of a good deal of conversation here, though it may be of too trifling a character to interest you. Dr. ABERCROMBIE has received a medical degree from Oxford! This appears to us to be strange, as we have always flat-tered ourselves that one from our own University was the best of any, whilst we have always ridicaled degrees from an University where medicine is not taught. Although to us the matter is inexplicable, you perhaps may see further through it. All we know is, that Abercrombie, though a very pious man, is a cunning, intriguing little fellow, and when he went up to London to be examined before the Parliamentary Committee, he made himself Sir HENRY HALrosp's most obedient humble servant, and toadied him in all ways, which makes us

hope of being useful, on the characters of those distinguished men, many of them removed from the stage, with whom I have been united, or with whom I have been in consultation on many trying occasions. By this intercourse my opinions have been matured, and now, through your kindness, I shall use the advantages which time and circumstances have given me, so as to pre-serve the record of the opinious and practices of the men who have raised the profession of surgery in these kingdoms to its present acknowledged perfection. By this, to me, eventful change, I am led to reflect on the advantages I have possessed, in my anxiety that your lordship and the council shall not have occasion to regret the decision to which you have come. The uranimity of the council, and the very flattering expressions of your lordship, lessen the regret which every one must acknowledge to be natural to me in leaving a society where I have experienced uniform kindbess and liberality, and in breaking the latimate and friendly relations with some of the most estimable men of our day.- I have the honour to be, my Lord, with great respect servant,

"CHARLES BALL "To the Lord Provest, &c." place that your will President must have sions, and that they were fully determ gree, in payment for the humility and vices" hitherto unkaben.

ST. GRORGE'S HOSPITAL. BLECTION OF A CHAPLAIN.

A VACANCY having occurred in the office of chaplain to St. George's Hospital, in con-sequence of the resignation of Mr. Walker, e candidates for the appointment were, the Rev. FRANCIS GREGORY LE MANN, and the Rev. Mr. NEVIN. The election, which was actively contested, terminated on the 8th instant in favour of the latter candidate-the numbers at the close of the poli being as follows

For the Rev. Mr. Naviw 156 For the Rev. Mr. LE MANN .. 81

Without attempting to institute any inquiry into the merits and qualifications of the candidates, it may be remarked, en pament, that the regret felt within the hospital, amongst those who are most proparly interested in the result of the election -the sick inmates-may be expected to be very great, at the non-election of Mr. La Mann, who by his kindness and attention to the sick, during the seven or eight weeks when he officiated in the hospital for the Rev. Mr. Walken, previous to his resignation, succeeded in obtaining the ap-probation and good will of every inmate of the institution. Mr. Le Mann is well known, by these who have the gratification of his unintance, to be possessed of liberal and elicistened senting nts, and an excellent knowledge of classical literature, having, at a very sarly period of his camer, obtained a fallowithp in King's Collège, Cambridge, Testianoulais of a very fattering kind relative to the fattiful and zealous discharge gh character, by whom he had been em-oyed as a curate; and had not the election on interfered with by the medical and surgical staff of the hospital (with the ex-ception of Dr. Wrisow and Mr. Walken), we is every reason to suppose that Mr. Le Many would have been elected by a triumpheat majority of the independent germbors, many of whom are much disguisted with the independ interference of the affind oligarcy, who for years past have affind oligarcy, who for years past have affidised in all the hospital appointments, gae frequently remarked, in the course of a finance, by the independent governors, the officious conduct of the Broden ty in all matters relative to the heapital

a the means of sending him the Oxford to shate the anisance by withdrawing their we was the amazone of "attendance; their support and influence against as the term of their annual subscriptions should have expired. We were influence, and believe it to be correct, this Mr. Nevre has not had the liencity of a collegiste education. The conduct of one of the medical officers, when same is unworthy of mention, has met with the severest reprobation. At the commencement of the canvair, he announced that he was favourable to the election of Mr. Le Mark, and actually tendered to one of his friends, instructions relative to the most appropriate course to be pursued in order to obtain the chaplainship, although at the very time, the hypocrite was actively canvassing for the other candidate. Personal exposure and rebuke, however, have followed this deception, which the party is not likely to forget during the remaining days of his earthly pilgrimage.

> The British and Foreign Medical Review. Edited by Joun Ponucs, M.D., F.R.S., and JOHN CONGLLY, M.D. No. 1. London. Jan. 1836. Sherwood.

A waw candidate for the favours of the medical profession has wedged itself in amongst the periodicals, between the Medico-Chirarpical Review, and the Edinburgh Medical Journal. Which of the three at last will go to the wall we pretty well know, but object to slarm either party by publicly stating. We are well enough pleased to see the work, as strenuous friends of comnetition in all the departments of medical science. Who, indeed, have more reason to he pleased with rivalry amongst periodicals? We have witnessed the life and death of of his ministerial duties were produced in twenty claimants of that class since the farour of Mr. La Mann. feem clergymen of year of our Lord 1823, each new "journal," most Lenote and all, by thrusting itself beneath the pedestal of Tax Lawest, serving as an additional lever of elevation to thi work. 1. 184

The Editors of the British and Fornis Medical Review pame forward professedig an chiaffy, we believe, with those two ex their project; first, that fireign me rature had not obtained the attenti it descreed from the existing a rindicale of these countries; and, see that the criticisms and analyses of Engl works, which appeared in our quas y in all matters remove to see day the provinced them. From attending the medical journals, were not "tree and common, as well so from roting at elec-

the possessing a competent knowledge of cul journals in this country from being very rience and efficient acquirements, ind 'qualified to undertake it," to " inexperiyouths of " unexercised judgment."

This was a tolerably smart slap in the face for Messra. Jourson, (senior and junior, according to the title of the Medicu-Chirurgical,) with how much justice or decency inflicted, we profess not to say. Such, attempt was made to laugh down the new editors, as they were seen rising through the trap-door, with the announcement in their mouths that they appeared as " writers of known and unquestionable respectability." We are obliged to presume that this character was assumed by the Editors in their own persons, because those gentlemen are the only "writers" who are stated, and are, therefore,acknowledged and known, to be contributors to the first number of the new journal. Or was this an oversight, and contrary to a possible expectation, after such a declaration, that the name of each critic or analyst would be attached to his respective article?

In considering the question of "success" in the establishment of a new periodical, the point of debate with the projectors is -or ought to be-generally, that of the means of the class of persons to whose interests it is to be deveted, or whose attention it is designed to arouse. To talk of there being "room" or "no room" for a new work is abourd. There is always abundance of room where the azena of felt, or not in want, or already supplied, or views of the presiding genius, except subtile in riches, and we correlate suspect when the declarations are adverse to be one or other of these conditions will some of medical reform. province the career of three quarterly made. It would puzzle us, for instance-

o a line medical and

the previous Regulaters of such article, or producted. Why, Mr. Reiner's quarterly 'as the work received might demand," | journal is but just dead! The Edinburgh were not whe productions of man of expe- has long cossed to circulate any where but s- amongst a very select for at home, and ' pendent of the influence top evident'in some hundred or two suggests on movel the heaty productions of jurgaille sail in stations absend; Dr. Jenteson once had considerate writers,"—that the task had such a struggle for it, that nothing but the men " hitherto confided to persons little excitement of change, backwards and forwards, from quarterly to monthly, and 'enced reviewers, however able (!)," " to | monthly to weekly, and weekly to quarter-"misrepresenters and critics of limited by issues of his work, kept it in life and be-"knowledge," " uncandle persons," and ing; and last, though not least, one of the editors of the new journal has already experienced a signal failure as editor of a medical periodical. As, however, there may be purchasers enough to sustain one quarterly journal, it must be a strife of industry. we suppose, amongst the Editors, whose at least, they felt it to be, whereupon an shall be the better production, the last speculation, however, always working under the disadvantage of infancy. Of " induatry," we say, because the labourers in the field of literature are open to the engagement of all, and that redselver would be unwise, indeed, who would work with the aid of inferior talent, when better was to be obtained.

By-the-bye, there is one division of the field in which no quarterly journal has yet mained a character, or even sought it,-that of medical politics, -taking arms in favour of free and liberal medical institutions. Not that any one of them has eachewed the question : but each has either at once declared an open enmity to thorough medical reform, or has second at its noble and generous views, or has with one hand tried to retard its progress, while aiding it with the other. Thus have we seen the most diverse and opposite views in one number of the quarterlies, on the subject of medical gevernment,-good principles, and wretched and impossible details; or correct details with expressions of horsor at sound principles. There mever seems, indeed, placed Marriage it not provided with obstacles to over them that watchful eye, and that matter crucked by the law, — where there reviging hand, which are essential to ensure the liberty of the press. But; though high and starting character,—and heapire whole acres of "room" for the confidence in the sentiments and on of marte, there may be more more expressed in the name of " We," and stable than buyers; the buyers may be reader never appears to detect the ri

at worth! you divine the principles that build be defined on the views which preall in the new journal. Thus, at page 2, re find a most unhappy sigh over " medical petruction," doubtless in consequence of ome obscure impression on the part of the rriter, that " Government" is about to adopt change in medical law which will tend to increase the amount of learning and cientific acquirements" in the medical refermion of England,-that is to my, serally, to upset the ticket and certificate ystem in medical education. Yet at page 6 is to be found the following unconsciously ttered mathema against that very system; which for us to explain and apply is superluous:

"The number of young men sout to their tudies in Lindon, is, we apprehend, coniderable; and the same ever look upon the outbful, ardered, they are thought countenances of the junior student, they dominencement of each assion, without our shoughts being arried to their several homes, where florts are making, and secrifices, of which oung students are not always mindful, and thich give something of solamnity to the acit engagements so soldly entered upon y their public teachers, in years which are bettermine whether or not those sacrifices re to be made, and not a few parents, mistigeties to be endured in vain."

"Sacrifices," indeed! Sacrifices to the pd Manmon, in the temples of the "recognized" hospitals and schools, the College, its Halls, where, for simple hits of worthless appr., thousands upon thousands of pounds a annually exterted from the "anxious areats" of the certificate-lacking stadents he sholition of this system, on the out and, and its sacred preservation on the ther, are the ultimate points for which sadical reformers and the monopolists everally struggle.

Of the execution of the new Review, we see yet hardly perpared fully to speak. The six article, however, is injudicious enough assignize, six. Is it for the production of the single works,—articles not of the alightest six himse—that the projectors continued a new modical journal necessary in

the the shiple there erems to have been been been to be the send of the send o

ine of Lose of the Planus and Mr Appendages, when After Delivery, with Remarks on the propriety of removing that Organ, in Casel of Interdion or Melerins. By John Crantin Tookie, M.R.C.S.R., &c. E. Ooz, Bushwark, 1836. pp. 22.

Faom a little pamphlet which has just been transmitted to us under the above title, we condense the following curious statement:—

Case.—At four o'clock a.m., May 22, 1835, Mrs. Aston, midwife, of Coventry, was requested to attend a woman in labour, who she found had already been in labour forty-eight hours, upon her knees, insisting upon being delivered in that position according to the custom of her country, Ireland. When induced to lie on the bed, an examination of the parts showed the os tincz dilated to about the size of half-a-crown; the child's head presenting as usual. Every thing went on well, and the woman was delivered at 7 o'clock, the same evening, of a living child. The placenta followed whole in a quarter of an hour, being expelled by a pain. No hemorrhage ensued at the time, although a considerable quantity of blood was lost during the night. The after pains were trifling, and she felt so well, that she pertook plentifully of animal food immefiately after the midwife left.

At about four o'clock on Sunday morning, May 24th, Mrs. A. was hastily summoned in consequence, as the messenger stated, of the appearance of another child. The woman had risen during the night, and had gone: into an adjoining room to make water; when her screams alarmed her lossband, who called in some of the neighbours, and found the woman scated on a stool before the fire, with a vessel of warm water in front of her, and a large substauce, which they compared to a child's head and nack. lying between her thighs, supported by her hands. The hemorrhage had been profuse. The midwife found the woman on the bed, pale from loss of blood, and in considerable pain. The blood had even run on to the floor. The uterus was lying on the d. loosely connected to the vagina by a mbrane only. It was removed shred of the without effort, and p seed in a bowl. The eed, and next morning hemorrhage then enamed, as the midwise brought the s father, who discovered, to be that it was an uter o'clock he visited the woman. completely exhaust her arms ab expense of

The second secon

any sensation like bearing down, nor of any established, she again gays the child the substance lying in the vagina, nor of suffer-breast, and persevered in doing so during ag much pain: neisher was these much several weeks, until, finding that one must no distention of the abdomes. We was there then or at any time during the progress of bille attack, the tongue at no time enhibited the case, any thing more than a slight degree of tenderness, which, however, was hardly and sallow as before, and she complains of parent on the left lumbar region only. The only part of the uterus and its appendages not found in the bowl, was the left ovary. The uterus, on inspection, was a heavy, hollow, but firm pyriform body, very nearly as large as an ordinary child's head, at term. No leceration was visible, except a slight rent in the posterior lip of the os uteri. The attachment of the placents was distinctly marked, being of a deeper brown red than the remainder of the mass; a quantity of flocculent matter adhered at its site to the walls of the uterine cavity. It was inserted over, and concealed the opening of, the left fallopian tube. This orlfice was easily discovered by detaching a small portion of the loose flocculent substance. The vessels were large and tortuous, and fully accounted for the great hemorrhage. Upon making a section along its anterior aspect, the broad ligaments, with both fal-I lopian tubes, and the right ovary, were discovered. The funbriated extremities of the tached, and to have remained in situ.

My father judged it prudent not to institute any examination per vaginam, fearing. also, that any salutary union of the aides of the vagina might thus be retarded, and risk an ulterior prolapsus of the abdominal viacera. He enjoined perfect quietude and absolute restriction to the horizontal position, abstaining from active medicine, and ordering a light farinaceous diet,

May 25. Monday morning. The patient had risen during the night, and passed her urine freely. She had slept, and appeared Toas well as on the previous evening. To-wards evening she passed several small scybale. She went on without accidents, except some increase of tenderness of the side, and some degree of fever, and diarrhera on the 27th of May, which continued for three or four days, but which was then the that and from that time she gradually that her health and strength.

to her confinement, milk was in considerable quantity, but imther the loss of the aterus, this together with that of the lochis, ed, yet she persisted in applying a sailed, on the breast, which included one, loose connection with the vagina.

It is equally difficult to account for the region attended, with nation should be at it received of the uterus; or so saile a fit occurred, an from the appearance graciting chuss being removed. When sented on examination, is most been

The woman did not much complain of her health had been in some degree rea good deal of debility, but not such as to preclude her from following her usual occupation.

> The child was for a long time in good health, but about a month since it was attacked by diarrhosa and died.

Principal Physiological Phenomena. Those which present themselves in the history of this case are, the sudden and immediate suppression of the secretion of milk, and the absence of any flow of the lockia. So triffing indeed was the quantity of the latter, that the napkins were but slightly soiled; the hemorrhage too was complisely arrested, as she did not lose a drop of blood after the morning of the 24th (Sunday). There is this additional pacularity connected with the former fast with the farmer this additional pacultarity connected with the former fact—viz. that the milk had already appeared in considerable quantity before the loss of the uterus, but was entirely and permanently suppressed within two days after the separation of that organ. It tubes were particularly clear and distinct, this fluid that the woman persisted in applying the child to the breast, and, impressed with the same idea, she continue do so until within a short period of the child's death, when finding her efforts vain, and that not a drop ever exuded, she finally desisted. She was repeatedly remonstrated with upon the subject.

> The absence of all peritoneal inflammation, also, is a circumstance particularly worthy of remark, no means being taken to prevent it. The only symptom which ever caused any anxiety as to peritonitis was a slight degree of pain in the left lumber region. The great quantity of blood lost when the uterus was separated, might in some measure serve to explain this singular fact? With regard to the violence which effected so complete a removal of the uterus, thirty-six hours after delivery, it is almost impossible to conceive it to have been offered by the woman herself, and yet such, there is every reason to believe, was the fact, if violence alone can suffice to accoun for such an event. The midwife most po tively amerts, and her statement is sta corroborated by the neighbour who first the woman on the morning of Sunday, that no effort was required to remove it from

> It is equally difficult to account for the inversion of the uterus, or to smit when it occurred, sin from the appearance pass

pened spontaneously, no traces of any violence existing, and no portion of the placents or other body remaining, by which sufficient traction could have been made. Provious to its descent on Sunday, nothing, which could have led to any suspicion of such an event, had happened.

The fact of none of the viscers following the uterus, and the total absence of bearing down, are equally inexplicable, unless we adopt the idea that the rectum, distended with fecal matter, had fallen forward towards the pubes, and closed the sides of the vagina. Yet the woman had not the slightest difficulty in micturition. I have not been able to ascertain whether she passed urine on the night of Friday. This circumstance will, perhaps, bring us nearer the epoch of the inversion of the uterus, as it is difficult to suppose a body of such magnitude to have been in the vagina without obstructing the flow of urine. Owing to her constant refusal to permit any examination per vagi-nam after recovery, I am not able to describe the parts at the present moment. Probably the vagina forms a cul-de-sac, in consequence of the adhesion of its opposing surfaces. Sexual intercourse has repeatedly been had with her husband, no mechanical obstruction existing.

In connection with the loss of one ovary, it is interesting to be able to state, that, although no impediment to coits exists, yet the usual feelings and desires are entirely wanting. This might have been anticipated had both ovaria been removed, but one still remains in situ. Of course the menstrual discharge has never reappeared; even the small quantity occasionally furnished by the vagina has not been observed.

The history of this case demonstrates the possibility of removing an organ so voluminous and essential as the uterus, together with the ovaries, fallopian tubes, and ligaments, with only a slight impairment of the general health.

A question has been raised—Can a woman, after extirgation of the uterus, ever become the subject of an extra-uterine conception, should the vagina not close and form a culde-sac? It is obvious that nothing of the kind can ever happen to the woman whose case forms the subject of these pages, as the left overy was the only portion of the nterine appendages not found in the bowl, and all attend feeling is extinct.

I have not met with any case which may thirly be considered as parallel to the presist. In all the other cases the mamme became wasted and absorbed in the present instance they are still prominent, but this, I fallsh, imply be attributed to her perseverance as permitting the child to suck.

MODE OF

REPRODUCTION OF BONE APTER . EXPOLIATION.

In the Beinburgh Medical and Surgical Journal for January 1835, we find an article of which the following is a condensation. It occurs under the head of "Clinical Report for the Summer Session, 1825. By Mr. James Syms, Surgeon to the Royal Infirmary: "—

There are still several circumstances in the history of necrosis which remain very mysterious. One of the most interesting of these, is the process by which exfoliations comprehending the whole thickness of a bone are reproduced. Sometimes nearly the entire shafts of the tibia and humerus come away. But we have seldom an opportunity of investigating by dissection the reproductive process at a stage sufficiently early for discovering the nature of the steps by which it accomplishes ossifi-cation. In the case which is now to be detailed, the process of reproduction had advanced just to the extent desirable for pathological inquiry, and I think it will go far to put at rest the long agitated questions on this subject :-

Case .- Beatrice Stokes, aged 13, strained her ankle by a false step on the 24th of March. Rigors, vomiting, and headache, attended with intense pain in the leg, and the usual symptoms of inflammatory fever. soon followed. She was sent to the Royal Infirmary on the 21st of April. From the middle of the thigh down to the toes, the limb was red, swelled, and tense, except at the fore part of the leg, a little above the ankle, where fluctuation could be felt. Incisions were made, a large quantity of thick dark-coloured matter was evacuated, and the patient greatly relieved. Through the openings the bone was found extensively denuded, and it became necessary to amputate the limb. The recovery was tellious, but perfect.

Examination.—When the limb was examined, it appeared that nearly the whole articulating cartilage of the ankle-joint had been removed by siceration, leaving the bone bare and rough. The shaft of the tibia scemed to be dead throughout almost its whole extent, and had already undergoing considerable crosson by the absorbeing its junction with the cancellated between adjoining the epiphyses. When the finite was carried along the surface of the destroyer active and incision that had been made to expose it, a dense case or shell made falt, which, when displayed by dispersion.

the second

effed, with osseous matter deposited in its from having entered as a pupil this session substance. The membrane was traced dis- at King's College. tinetly from its sound part, where covering the epiphyses, over the dead shaft, and no one who saw it could doubt that it afforded the hed or matrix in which the new bone was deposited. Where covering the posterior surface of the tibia, though detached from the bone, it had suffered comparatively little change, which rendered its recognition at other parts more certain. The new bone did not constitute a continuous shell, but was deposited in flat masses, or scales, of various extent, between which the periosteum intervened so as to insulate them completely from each other, or any portion of the old bone retaining its vitality. The o-scous substance lay on the inner surface of the periosteum, with merely a fine film of the membrane covering it, but with a considerable quantity of soft getatinous, substance like coagulable lymph effused false pretences, he might succeed at one of over this, so as to line the interior of the case. At several parts of irregular size and figure, the periorteum did not exist, and at these parts there was a corresponding deficiency in the new bone. These apertures resembled the cloace, as they are named, which exist in the investing shells that are formed in cases of necrosis, and are usually ascribed to absorption induced by the pressure of matter confined within the bone. But it seems more probable, from this case, that the deficiencies in question depend upon the periosteum being destroyed at particular points in the commencement of

Remarks.-In explaining the history of this case, I think it may be reasonably supposed that the strain of the ankle occasioned inflammation of the joint, which extended to the tibia, and led to ulceration of the articular cartilages, and death of the shaft of the bone; that then suppuration took place under the periosteum, which having become at some parts disorganized, allowed the matter to pass outwards and distend the skin; that lymph was effused from the inner surface of the remaining periosteum, and also in its substance, so as to render it much thicker and softer than usual; and that then bone was deposited towards the inner surface of the membrane in numerous detached points, from which it was proceeding on as to make them coalesce, and constitute a cylindrical case to the shaft.

Changes of air continual symbol I can be compensated for the loss work improvement in the whole system and money which I have sustained The lungs are peculiarly adapted to suff

It appears to me, as the professors have not fulfilled their agreement, that a part, if not the whole, of the money I was obliged to disburse, on entering, should be returned to me. Dr. Bisset Hawkins, as you well know, has not given a single lecture this session, and in his stead we had nothing but a hum-drum Scotch parson, who preached most soporific twaddle to us. Professors Hawkins and Mayo are in constant strife, and as their resignation is considered certain, their lectures are proportionably slovenly and incomplete. Your candid opinion and sincere advice will oblige your sincere admirer,

A KING'S COLLEGE STUDENT. Strand, Jan. 6th, 1836.

. If the writer thinks he could establish a charge of obtaining money under the police offices. It is in the Bow-Street district.

Mr. Don has been elected to fill the vacaut chair of botany at the King's College, Straud. Between that school and the Charing-Cross Hospital, nothing decisive has as yet been arranged. The medical men of the Hospital who are likely to lose their appointments as lecturers in the Charing-Cross School, are opposed to the union. Into this Hospital several Poles in the most destrute state have been received, but when fit for discharge, starvation stares them in the face. They have no homes to go to. The officers of the establishment ask what is to be done with them, or what can be done for them?

A Practical Treatise on Urethritis and Syphilis, including Observations on the power of the Menstruous Pluid, and of the discharge from Leucorrhoes and Sores, to produce Urethritis. With a new Classification of Venereal Eruptions, and a proposal of a substitute for Mercury. Henry Judd, M. R. C. S. &c., Вy London. Highley. 8vo. pp. 568. With coloured plates.

CORRESPONDENTS.

Ciris has not framed his questions ver physiologically. They cannot, therefore, I answered in direct terms. The quantity of air To the Editor.—Sir, Devoted as you have | inhaled continually varies without voluntary theen to the interests of the medical stu- exertion. It may also be increased at pleathe process of imbiblion, and resort has frequently been had to them as media for administering remedial agents, but as yet, without marked and extensive advantage. It is not worth while to agitate the question (except in one or two diseases) while more obvious and less delicate channels of communication are readily approachable.

Mr. Someth will perceive, by the contents of the last week's Lancer, that his first was in print before his present letter was indited. The publication was unavoidably

delayed from want of space.

A correspondent complains of "a custom," adopted by a lecturer at the West End, "during this course of lectures, of occupying a large portion of the time of his audience, by calling over the names of about a hundred students two or three times a week." He agates that the practice is a "source of great annoyance to the majority of the class, whose attention is thus taken up instead of having it devoted to instruction." Another correspondent regards the "custom" as one adopted "with a view to displaying an array of names, of which the majority are not likely, for very good reasons, to find owners in the room. The class," he adds, "would he obliged by the absundonment of the practice."

Gound may be adjusted that his friend labours under an egradious deception. The results described are indicated. We should advise the party to state his case wally, one respectable medical government of the aborration from a state of health is not of the intellect, conviction of the history of his impressions must follow.

W. If the practitioner who made the charges, be qualified, legally, to practice as an apothecary, he would be enabled to sustain his charges in a Court of Law. At any rate, the lady would be placed in a worse position than the one she now occupies by resisting the payment of the demand. On the 'bardship' of the case we cannot express an opinion.

To the Correspondent who dates his letter." Thready mouning."—As the matter has been brought an directly under our notice, we will examine the production, and next next state the result. It certainly, however, was the business of our Correspondent to prevent, in so brief a compact, the third sources of complaint.

LECTURE IX.

LESIONS OF INTELLIGENCE IN CERE-BRAL HEMORRHAGE.

GENTLEMEN, - Lesions of intelligence form the next part of our subject. Like lesions of motility and sensibility, they should be divided into such as precede the hemorrhage, and such as occur after it has taken place. In most cases of cerebral hemorrhage, the individual enjoys the faculty of intellect undisturbed up to the very moment of the attack. There are no premonitory symptoms on that side; however, in other cases, we observe some change in the intellectual faculties which precedes the invasion perfect come, from which no kind of exof the disease by a greater or less interval, citement can rease kind, or into which he
Thus the intellect seems lazy, and incapable quickly relapses, even if he shows some of any effort. The individual seeks repose feeble indication of remaining sensibility, of his mental faculties, and has a constant Do the different states of intelligence, durtendency to sleep, from which he is with ing the moment of an anopleric attack difficulty roused; others, on the contrary, exhibit an extraordinary degree of irritability and exoftenent. Thus we have seen an indisting in whose the access was preceded by great physical agitation and constant deof motion; it was impossible for him to to lesion when the injury r others become cross and quarrelsome does pathological anatomy. so there become eross and quarrelsome idoes pathological anatomy is days before they are attacked, and ficient data for lecalizing themselves up to violent fits of passion, any one of its interespon face titling almost manks. It is not easy to to me to be established, it may be taken to be established, it may be taken to be established, it may be taken to the disorders of conditions of the interest passions, apoplery. We are carefulful heaterfragely, department, because the interesting of the effort of the conditions of the

norance than really advancing knowledge. Some patients present divers hallucinations of the senses; thus the memory is some times lost before the attack of hemorrhage : the individual for a few minutes is unable to say where he is or what he does. In other cases all the senses are implicated, and the patient falls down in a true state of come, from which he unexpectedly recovers. We may now ask, What occurs at the instant of the effusion of blood into the brain?

How for are the Intellectual Faculties modified. during the actual Effusion?

In some cases the intellect remains intact amidst the trouble of the other functions. It is not certain, as authors say, to find the intelligence abolished at the instant of effusion. Cases have been observed where the sensibility and power of motion were completely destroyed, yet the mental faculties remained untouched, and this especially takes place when only a small portion of the curebral substance has been compromised in the lesion. Sometimes the intelligence becomes more weak and dull in proportion as paralysis affects the limbs; the patients become stopid; their language is incoherent and unintelligible, but conscioueness still remains. Finally, in some cases, the loss of intelligence is, as you all know complete, and the patient lies in a state of the most depend upon

Differences in the Seat or Intensity of the Hemorrhage?

Are the intellectual faculti

intense or extensive, the intelligence is moderate effusion into the substance of the abolished, no matter in what region of the brain the lesion may be situate. Again we may ask, Does the modification or loss of intelligence occur only in cases where the hemispheres of the corobinin are engaged in the lesion? This is a point sustained by several physiologists, who attribute the acts of intelligence to the cerebral hemispheres and their convolutions. But what do facts teach us? That complete loss of consciousness, and, of course, annihilation of all mental power, may coincide not only with hemorrhage situate in all possible points of the cerebellum, but also exists in cases where the effusion has struck another organ than the cerebral hemispheres. This latter fact has been frequently observed. We need only call to mind the analysis which we made during the course of our last lecture, of thirty-two cases of hemorrhage into the substance of the cerebellum; in several of these, the intellectual faculties were more or jess abolished, although that part of the brain to which their manifestation is commonly attributed re-mained intact. When the mesocephale (the pons varolii) is the seat of hemorrhage, in what manner is the intelligence modified? Does it suffer as when the cerebrum and cerebellum are the seat of lesion? Certainly, and even in a still more marked degree. all the cases that have been observed of hemorrhage into the substance of the pons, the action of the intellectual faculties was suspended, because lesion of this central reunion of the brain, cerebellum, and chord, is always accompanied by more or less complete and prolonged coma.

We may lay it down as a general principle, that

Hemorrhage of the Spinal Marrow,

into any portion of it, does not give rise to modification or abolition of the intelligence; this is readily conceived: however, the rule admits of some remarkable exceptions. In have been dissipated; animal life returns, a few rare and curious cases, effusion into the superior portion of the chord has produced a reflected effect (retentimement) on the brain, from the law of mutual association, by which all the various parts of the nervous system are linked together in one harmony and in unity of action. A case of this kind, which deserves peculiar attention, has been titled by Dr. FARRE in his inaugural dissertation for the year 1832 (" Propostions and Observations on several points of Surgery and Medicine," No. 153). Here the patient, a man advanced in life, was carried off by an attack of apoplexy, accompanied off by an arrace of apoptery, according to the property of the light o

anterior pyramidal hodies on the left side.

We have now passed in review the various modifications which the mental faculties present, either before the engarrence of the hemogrhage, of at the modern it takes place. It now remains to consider the state of intelligence

After the Effusion of Cerebral Hemorrhage has been completely established.

In cases where the hemorrhage is very violent, coma persisti, the intelligence is absolutely abolished, and death soon overtakes the patient in this condition. When the effusion is less extensive, the state of coma generally disappears after a longer or shorter interval, leaving the intellectual faculties in various degrees of integrity. In a very small number of cases, the patient recovers the perfect use of his mental powers, but this unfortunately is a rare exception. In a great majority only a part of the intelli-gence is restored, and that gradually; offusion once accomplished, leaves traces that cannot be perfectly effaced from the mind. the habits, or the passions, of the individual. Thus, in general, after the occurrence of cerebral hemorrhage, we observe some weakness of the intelligence, and this in patients who had not lost it during the instant of the attack; the powers of the mind are here evidently reduced; the patient is unable to apply himself to any serious mental occupation; profound meditation is fatiguing, and even injurious; in a word, the intellect, attacked at its source, is incapable of any exertion beyond that necessary for the most ordinary occupations of life. There are other patients who are not so happy, In some cases the alteration of the intellect is still more grave; the individual is not so fortunate as to recover even a portion of his mental faculties; thus we see a certain number of persons, who remain in a state of the most wretched imbecility or idiocy after the first symptoms of cerebral hemorrhage but the mind is gone for ever; it is rarely that this state ameliorates; the depravation of the intellect generally increases up to the moment of death. In the moral conditions which thus accompany effusion of blood into the brain, I have sometimes had occasion to witness a curious modification of the cha-racter; the individual, induced to a state of complete infancy, bursts like takes at the least contradiction; even when spoi with kindness, he sometimes crick and without our being shills to discover all mediate cause for this manifestation of ordered schalblity. Others, again, full I an acute state of mental derangement; stead of imbecility it is mania, which clares itself as a consequence of small

wish a storile delirium, similar to that so how are we to resolve it? By an appeal to often seen in connection with isolammation facts; by an analysis of such cases as have of the contents of the cranium, and in there been published by others, or observed by cases we problem have such an accordant to the membranes cooking portion of the creater he legion resided in the or inflammation of the membranes cooking portion of the creater he headers are the caffected handsphere; the delirium, then, soribed by M. Boulland as the instrument may be rejected rather as a complication of speech. than a consequence of apoplexy. The intelligence may not only be lost, or weakened one part of it may be more or less modified Thus certain patients, after an attack of degree of judgment, of wit, of imagination, &c.; but the memory is completely lost; in other cases, again, the memory is only par-tially attacked; the individual remembers everything, for example, execut the names of things; he cannot call to mind a single substantive in his native language. We substantive in his native language. shall return to this curious point in the history of cerebral disease at a future time.

Affections of the Speech.

In our last lecture, we saw how the power of speech was sometimes completely de-stroyed by effusion of blood into the hemiof articulation; the aphony then was symptom of paralysis; but language requires not only the action of the tongue (for were this not the case, all animals being possessed of that organ, should speak), but in addition that loss of speech may occur with the exto the power of moving the tongue a certain istence of the lesion in very various portions
action of the brain that dominates the musof the brain. You will also find in the cultar action, a guitting inquence which co-ordinates the movements of the tongue and, frequently quoted it, we shall mention again larynx, and gives rise to that harmony which is necessary for the production of speech. students of the production of speech is this certain, then, that a peculiar portion of years of age, who presented hereit is a most remarkable one. The students of the observation was a femiale 30 the brain is destined to regulate the forms—ward in La Pitie. Three years before, the is injured, we have a species of aphonia quite other symptom of any consequence was ob-different from that formerly alluded to. In served. When we saw her for the first some cases of cerebral hemorrhape, we have it time, complete aphony existed, yet the pa-complete loss of speech; in others the mo-tient could move her tongus in all directions. tions of the tongue remain free, and the and thrust it out whenever she was desired. motions; this proves that we have somemotions; this proves that we have somein the alteredia the one set of cases, which
in the biner set, remains intact; but what
it this something? what is the nature of the
alteration upon which the loss of speech,
death we found a ramellimental of the
alteration case of apoplary, dopends? A posterior extremity of the corpus striature,
on the left side, not larger than a good sized,
and the string labed professor of the formation per, a similar lesion, nearly identical in ifficial to the authorice extrementy of each primary misphore, because, in all the cases he cocupied the centre of the university, the contraint observe, where the power of centrum ovale of Venusenius.

Thus you see, on the authority of the brain, which are irretramble, that loss of the brain, in the correct as it is by the option of the interest of the contraint of the primary conditions with a lesson of the standard of precising is not abolished with a

I have found thirty seven cases of this kind; thirty-seven where the lesion was confined to the anterior lobes. Now, of these thirty-seven, the power of speech was completely lost in twenty-one cases, and preserved in sixteen. This disproportion is as you see not very great, and hence we conclude that lesion of the unterlor extremity of the hemisphere does not necessarily bring with it loss of the faculty of speech. However, we should remark that this does not prove strictly that the power of employing language does not reside in these anterior lobes, for, perhaps, in the sixteen cases we have cited, the legion was small, and the minor degree of intensity may possibly explain the absence of the

Again; I have found seven cases where the anterior lobes were intact, the lesion residing spheres of the brain. In the cases thus exclusively in the posterior, yet here the best alluded to, the phenomenon depended similar of speech equally existed. Finally, we collips on paralysis of the muscles which move lected seven more observations of loss of the tongue, the chief mechanical instrument speech with equation into the middle loss of of the hemispheres.

After reading these cases, which you will find noticed in the fifth volume of "Clinique," it is impossible not to conclude that loss of speech may occur with the excular action, a guiding influence which co- same book a case, which though we have tion of articulate sounds, and when that part had been seized with loss of speech, but no brain preserves its power of directing these the intelligence was intact, and the faculty of sensation and of motion remained free dished professor of the school, M. on the left side, not larger than a small sized larger, than a small sized to the americal extremetry of each form, colour, and extent, with the former,

considerable alteration of the anterior lobes, in others frequent; bowever, it is oftener the parts described by the physiologists we slow than quick i healty, in other cases, the have alluded to as being the instrument of pulse is feeble, soft, and smally compressible speech. This conducts us to an explanation of the reason why so many different theories have been formed as to the organ of speech in the brain. Each observer, struck with the coincidence of a certain number of facts, tion, or on individual dispositions. has built up his theory upon them, to the exclusion of all others; but they have commenced to generalize too soon. Thus M. RECAMIER thought that loss of speech coincided with lesion of the middle lobes of the cerebrum. M. SERRES, with alteration of the corpora striata, because he saw a few cases in which the patient was mable to speak, the effusion having its sent in that part. Finally, M. BOUILLAUD, as we have already said, placed the instrument of speech in the anterior lobes. I fear, that all these conclusions are premature; they cannot evidently all be correct; they appear premature, because not only is the faculty of speech abolished with lesions situate in various portions of the brain, but this symptom occurs when the lesion, exists elsewhere. Thus M. LALLEMAND (Letter 2, page 134) mentions a remarkable case in which the power of speech was completely lost, although the lesion, a ramollisement, was situate in the left lobe of the cerebellum. From these different considerations we conclude, that here, as in a thousand other cases, it is impossible to localize the seat of language from pathological observations.

In our last lecture we saw how hemorrhage of the nervous centres was accompanied by various alterations of the intel-lectual faculties, of sensation, and of motion. The functions of nutrition also are more or less modified; let us now examine these : and first for digestion.

The Digestive Functions

however, which we may observe in many respiration are affected much sconer, even cases, viz., a more or less obstinate constitution the hemorrhage may not be conpation of the bowels; the muscles of the riderable, and the same remark applies to intestinal canal and rectum in particular, do the spinal marrow. When the lexion of the not act with their accustomed energy, and cerebral hemispheres is very extensive, when been already said on the latter subject.

The State of the Pulse

aton takes place, the pulse is fell and strong; in entirely, the propletting and the

under the finger. These diverse conditions are not necessarily connected with the immediate disease, but depetit, wither, perhaps, on an antecedent state of the circulastate of

The Capillary Circulation

resents itself with several differences. During a length of time it was said that if the patient's face was red, the conjunctiva injected, the figure swollen, &c., the case belonged to what was denominated sanguineous apoplexy. On the contrary, when the face was pale, we had to apprehend a serous apoplexy: we cannot allow these distinctions in the present state of the science. Several patients who have died from true effusion of blood into the substance of the brain, have presented a remarkable paleness of the face. This is by no means an uncommon occurrence, and shows that symptoms taken from the state of capillary circulation about the face are not to be relied on. We may conclude by remarking, that amongst the phenomena which precede or follow cerebral bemorrhage, we sometimes observe small effusions of blood underneath the ocular conjunctiva, or a more or less copious hemorrhage from the mucous membrane of the nares.

Respiration

is certainly the function of nutritive life which most frequently undergoes modification in consequence of cerebral hemorrhage; but in many cases the respiratory organs remain quite free from derangement. Thus when the effusion of blood-is slight, occupying but a small portion of the nervous pulp, respiration is not modified in any remarkable manner; on the contrary, when are in general but little influenced by the the lesion happens to be scated in the autocourrence of apoplexy. There is one effect, stance of the mesocophale, the organs of not act with their accustomed energy, and cerebral hemispheresis very extensive, when even the mucous membrane seems deprived a large quantity of blood has been suddenly of a portion of its sensibility; hence drastic effused from the vessels of the highly, then purgatives often fall to produce evacuations.

The state-of the circulation also presents at once assumes that genular character so certain grounder, but as they follow nearly generally known under the name of "stagethe same laws for apoplexy as for cerebral congestion, we refer you back to what has non is one of a dangerous nature, sand in nour cases dangers has assumed has a source-blass dashes assumed has a source-blass dashes assumed him to the latter subject. most cases denotes the approaching of the individual struck with apoplexis The State of the Pulse probably depends on a lation of the particle of the par be laid down for the changes which it may jury of the brain. Experiments teach us present. In some cases, at the moment affur that if we instant that pain of prives

embarrassed, the pulmonary circulation in- affusion of blood into the cerebellum, has terrupted, and the lungs themselves sur- not been frequently observed. We are accharged with blood. Now this is exactly quainted with only seven cases of this kind what happens is severy cases of apoptery, where the patients almost universally die from embestissiment of the respiration. Re-mark, however, that the peculiar state of the respiration to which we now allude does not of necessity accompany all cases of cemebral hemorrhage. You will meet with several examples of the contrary, and would fall into error were you to conceive that stertorous breathing is a fixed symptom of apoplexy of the brain. How far are

. The Secretions

modified by hemorrhage of the nervous centres? Upon this point we have very little to say; in fact, nothing constant has been observed of sufficient importance to merit a particular examination. In our last lecture, when treating of paralysis, we touched upon the retention of urine which sometimes occurs in consequence of apoplexy; we pointed out the necessity of attending to the state of the bladder and intestinal canal. It is useless to repeat what we have said upon that occasion.

We have now successively reviewed the influence exercised by hemorrhage of the nervous centres on the different acts of animal and organic life. We have, in order to complete the subject, a few observations to offer on the phenomena presented by

The Reproductive Organs.

Physiologists were long ago struck by the fact, that in certain cases of cerebral hemorrhage, the patient exhibits a symptom that would seem rather to belong to perfect health; this symptom is erection, which, as I have just said, has been noticed in connection with apoplexy for many years, although no explanation was attempted to be given for this unusual phenomenon. Certain authors, indeed, compared the erection which manifests itself occasionally in patients attacked by apoplexy, to the phenomena of strangulation, and referred this apparent stimulation of the genital organs to a sort of asphyxia, -- to a reflux of venous blood,—to a profound trouble of the respiration and circulation. The question remained in this uncertain state until the time of Gant, who, in his destrine of the localiwhen of families, placed the regulating ower of the genital organs in the cerebel-This theory has since then been recoloud with a considerable share of favour. many physiologists will now tell you That if symptoms of inclination about the months organs manifest themselves in the course of any disease, the chief cent of the on, or irritating cause, is to be found in the cerebellum. However this may be, the solucidence of election, or other symptoms paramet of the generative organs, with | + Chaires die Hopitax, t. 1, p. 79.

where erection or other signs seemed connected with apoplexy of the cerebelium; while, on the other hand, the same phenomenon has been seen accompanying hemorrhage in various other parts of the cerebrospinal axis. It is a remarkable circumstance that in the seven cases of hemorrhage of the cerebellum to which we allude the effusion always existed in the middle lobe; nowhere else. Of these seven, six have been published by M. SERRES, either in the Journal of Physiology, edited by M. MAGEN-DIE, or in the second volume of his Anatomy of the Brain,* I cannot just now call to mind which. The other was observed by M. Guior, + and in this also the lesion occupied the middle lobe. We may cite one of M. SERRES' cases as an example. The subject of the observation was a female 70 years of age: she was struck with apoplexy, and although at this advanced period of life, her menstrual discharge returned at the instant hemorrhage took place. Afterdeath a coagulum was found occupying the middle lobe of the cerebellum. The genital organs presented even a greater degree of erythism than is usually seen at the period of men-struction; the uterus was filled with coagulated blood, and the inner surface of the fallopian tubes, together with the ovaries, were excessively vascular and injected. You must now be struck with the coincidence in all these cases between the symptoms and reat of the lesion. In all, the effusion took place into the median lobe. We do not find a single example on record of erection, or any other excitement of the generative organs, being produced by hemorrhage into either of the lateral lobes. This circumstance is remarkable. However, we have to observe, that whenever bemorrhage to any extent takes place into the substance of the middle lobe of the cerebellum, this part of the organ is naturally distended, and, from its position, must exercise more or less pressure on the superior portion of the spinal marrow. Hence we are unable to say with certainty, whether the phenomenon of erection &c. may not depend on this latter cause, as well as on the actual lesion of the cerebellum. There is something in this subject that is not very easily explained or understood, something that disagrees with our notious of disease in general. Is it not strange that the accident connected with the reproductive organs should be diametrically opposed to what we see taking place in all the other systems? The general phenomena

These six cases are to be found in the "Angtomy of the Brain." Five refer to makes; three were of erection; the sixth is that of the festale whose seek is noticed by the lecturer.—Rep.

of cerebral hemorrhage are passive: in all the mode of treatment I pursue; and also the other apparatuses we have signs of in- of pointing out to you certain errors which, action, of partylas, but here, on the continuous properties a state of action, a higare these subjects.

excitement at the moment the individual is In the first place, let me recall to your

withdrawn from all intercourse with the external world.

The question now before us is a complex one, and not to be resolved by a few experiments, or hy a few examples drawn from pathological anatomy. It is certain that phenomens of the same nature as those under discussion may occur when the lesion is situate far from the cerebellum. Thus erection, ejaculation of the seminal fluid, &c., have been observed in connection with myelite, with inflammation of the cerebral hemispheres, and several other disorders of the cerebro-spinal axis not immediately implicating the cerebellum. M. PINAULT presented to the Anatomical Society the case of an individual in whom the spinal marrow had been violently contused by luxation of the 5th from the 6th cervical vertebra: here there existed perfect crection for more than six hours. M. SEGALAS introduced a pointed instrument into various parts of the vertebral canal, irritating the middle and inferior portions of the spinal marrow, and erection and a discharge of somen were produced. Finally, atrophy, ramollissement, and various other diseases of the cerebro-spinal axis, are occasionally accompanied by accidents of the generative system. However, we cannot pursue this question any further; we do not profess physiology; our business is to investigate the morbid phenomena of discase, their causes, symptoms, and treatment. Let us therefore turn from this digression.

BURGICAL CASES,

DILIVERED IN 1836 AT THE

JERVIS-STREET HOSPITAL, DUBLIN,

24

WILLIAM WALLACE, M.D., M.R.I.A.,

Suggeon to the Hospital; and to the Infarmary for Biocases of the Skin, Venerual Diseases, and Diseases of the Urinary and Genital Organs.

PROLAPSUS ANI.-ITS PATHOLOGY AND PRINCIPLES OF TREATMENT.

I wast to call your attention this morning to the case of the infant who has recently died while labouring under the state covered by a visel's as called "prolapsus ant." It will afford me to a covered by a visel's as opportunity of explaining to you the visus which is have long entertained respecting the pathology of this dispust, and any visible posses."

In the first place, let me recall to your minds the particulars of the case to which I have alluded. When this child, who was about one year and a half old, was admitted, also presented a very wretched picture, but one which, I tagnet to say, is not unfrequently seen amang the lower orders of this city. She the content of the content

triments and a strained further on the attempted reduction in the manner in which lasteral than on the enterior or postector! I always reduce such cases; that is, by aspect of the tennews, and farther enteriorly than posteriorly. The remainder of the surtium to be pushed up first; and it was face of the firmour, or that of the southern quite outdent, that the efforth made in recruitments, had a less suporth and uniform appearance. It was paler, as if they are the contrast of the child, seemed to afford it much comints fort, and to trangullies it mosas and into folds. In short, it presented an appearance, so different from the remainder of the surface, as to force out by simplified that the structure of the two manner in which it was the contrast to be contrast to make the contrast to my con below the level of the more coloured and more vascular surface. This inequality was not, however, owing to any destruction by an ulcorative process, for it presented an appearance, merely as if the vascular surface was more loose, more pulpy, more vel-vety, and therefore more in relief, than the paler surface. The small end of the tumour had a rounded form, or eval, placed transwhole was not unlike, in its shape, the os ateri. The whole mass or prolapse felt firm and clastic, or like a tumour composed which was in its small extremity, was ulcerated, and so narrow, that it barely allowed the end of my little-finger with presence to pass in. When the finger entered about an inch, it reached a large sacculus, in which it could be moved about so extensively, that I could not feel the walls of the intestine. The child strained almost constantly, and every now and then there escaped some flatus, with which there squirted out a minute quantity of a slimy substance, of a mottled white and brown colour, more or less greenish, and having somewhat a fecuent appearance. The discharge of even a small quantity of this matter scemed to be siways followed by momentary relief. During the effort to discharge, the tumour was increased in tension and in size, and as soon as the effort subsided, it became more flaceid and less prominent, so that it might be said to be constantly and alternately projected and retracted. This appearance was not and represent which the solution of the country of the country leads on much owing to any portion of the country leads on accountry from the polving the country leads of the country of t

and this is the point which I wish you to pect that the bowel could be passed into the pelvis.

On making an examination of the rectum after reduction, the orifice of the anus. and the gut immediately within it, were so wide, that I found no difficulty in passing, to the extent of two inches, two or three of my fingers, and in turning them in the portion of the rectum immediately within the orifice of the anus. The portion of the gut which thus easily admitted my fingers, was versely, with a depressed centre leading that which had formed the covering of the into the cavity of the bowel, and on the large end of the prolapsus, and which was large end of the prolapsus, and which was now returned to its natural situation. Higher up than this relaxed portion, the bowel presented to my touch a firm and undilatof crectile tissue. The orifice, or opening able sensation, and when I passed my finger into this portion, I found it to be in a tight passage, the end of which I could not reach. I also found considerable difficulty in passing this indurated portion up into the pelvis, for there seemed to be some pressure downwards on it.

After the reduction of the tumour I directed two drops of laudanum to be given to the child, and afterwards she slept quietly for several hours; which, as I was informed, she had not done for many weeks previously.

Attention was, on my next visit, directed to the laying down a plan for the restoration of the digestive organs of the child, by food and by appropriate medicine. My efforts were, however, fruitless, as, indeed, was to be expected; for although the lufant seemed much relieved, and although the prolapsus never returned further than to show a ring of macous surface at the orifice of the anus, the state of emaciation and wretchedness continued to increase, and in eighteen days after admission she died; her death being preceded, for a day or two, by a tympanitic state of abdomon, with considerable pain on pressure, great thirst, and occasional vomiting.

On dissection, the large intestines were The mother admitted that the child had been other, and to the surrounding parts, and had this prolanges for several months; that in separating the adhesions it was evident for the last gir, upon the howel was almost that faculent matter had been efficied, and that faculent matter had been efficied, and that lattering the had several process, and that lattering the had several process, and that lattering the large intestines, their surface. On urand a several process, and that lattering the large intestines, their surface to the large intestines, their surface the large intestines, their surface to the large intestines, their surface the large intestines, their surface to the large intestines, their surface to the large intestines, their surface to the large intestines, their surface. least-affection. These ulcarations were more marks, I hope you have carried along with numerous as we approached from the open to the signoid ficture of the colon. The exper portion of the rectum was found sunk, or singlety awaginated in the middle portion, but was easily drawn up out of it. there being no adhesion between them. The rectum and the sigmoid flexure of the colon were now removed from the subject, and in doing so, I had occasion to remark that the sphincters of the anus were so clongated, as to form a much wider opening than could be considered natural to so young a child. Here is the rectum and lower part of the colon laid open, and here is a drawing of them :-

Here you observe a very prominent ridge in the upper part of the rectum, at which part you see that the bowel is quite contracted and strictured, and that this contracted state is upwards of an inch long. You also remark that the intestine above the contraction is greatly dilated, and, as it were, sunk round the narrow contracted ortion, so as to form a sort of cul de sac. You also remark that this contracted portion is ulcorated, and hard, and thick. The gut nearer the orifice of the anus than this, is free from ulceration, is contracted in its length, and thickened, and far more vascular than either the narrowed portion or the portion above it. It is evident to you, I am sure, that the vascular portion of the intes-tions surface formed the outward covering of the prolapse, that the contracted portion formed its orifice, and that the superior dilated portion was the part into which my prostate gland in a direction flowing finger passed, when it had ponetrated and backwards to the same. Its less through the orifice of the prolapse. It is about one men and a half. It is the also evident that the immediate cause of also evident that the immeniate cause of the arms of the manufacture into the cavity of the period from death, was the discharge of the contents of the meetines into the cavity of the period from the meeting into the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the cavity of the period from the meeting in the tens through some of these ulcerated open-ngs, and the inflammation consequent is called the internal Alti ough I have been misute in my re- which are so street with

or the manner in a principles which man. But, before I speak of this mechanica i I must beg of receive to the you to recold Excistive to the

You know name of reclum is tines which extends from the apper outlet of the pelvis to the man, and in adults measures, in general, about ten inches. It may be said to consist of three portions, a superior, a middle, and an inferior portion; and each of these portions has a direction, a structure, and relations, possible to itself. The superior portion, which resembles more than either of the others the upper division of the intestinal tract, is characterized by its being covered by peritoneum, which forms for it a fold, called the meso-ractum, and connects it to the back of the pelvis; by its comparatively cylindrical form; by its projecting loosely, in some measure. into the cavity of the pelvis; and by its direction, which is from above downwards, and slightly from left to right. It forms more than half of the whole length of the rectum, and extends from the sigmoid flexure of the colon, or from the brim of the pelvis, to the line where the intestine is destitute of a peritoheal covering, or to where the third bone of the sacrum joins the fourth. Where this upper portion terminates, the middle portion of the rectum commences. It is about three inches in length, is directed from above downwards, and from behind forwards, with a gentle curve. It corresponds posteriorly to the inferior part of the sacrum, to the coccyx, and to the ischio-coccygeal muscles, and anteriorly to the inferior fundus of the bladder, from which it is separated, inferiorly and externally, by the vesiculæ seminales and vasa deferentia; and more inferiorly by the prostate gland. This portion of the rectum bas no peritoneal covering, unless when the bladder is very much contracted; and even then there is only a small portion of its anterior surface covered by this mem-brane. Its structure is flittinguished by the great strength of its longitudinal assembler fibres. The third, the lowest, and the smallest division of the rectaes, extende in prostate gland in a direction doors and backwards to the attes. Its less a continuation of the mucous memi

the entestine, do not extend upon the lowest | my former collesgue in this hospital, Dr. portion. This drawing tolerably well re-

c Lower partion.

presents the form, direction, comparative size, and relations of these different parts of the bowel, and from it you may observe that they are so curved, in respect to each other, as to form a part of the letter S. But it will be found that these different parts of the rectum are distinguished from each other, not only by their directions, their form, relation, and structure, but also by the state of contraction in which they generally exist in the living body. Pass your finger within the anus of any healthy person, and you will find that it will be grasped by the bowel for a little way within the orifice; that is, as far, or nearly as far, as the inferior division of the rectum extends above this portion, the bowel is found to surround the finger loosely, or without making much pressure. This soft and lax state extends throughout the whole length of the middle portion, and exists whether the rectum does or does not contain feculent matter. If the finger be passed on still It is also equally clear, that if this state inforcher, we shall very often meet a sort of creases, the whole of the middle portion of ring, with a rounded soft surface. This is the gut will be protruded externally, the and from many others when I count and who arrives the coordinate the upper and lower thinking of the rooten are, when it can be a supported that the upper and lower thinking of the rooten are, when it is a supported that the man capable of exciting in ordinate tensor must or straining, is capable of causing a prolapsus of the anus; that this prolapsus

O'Beirne.

Let me now call your attention to the state of the rectum in an individual making an effort to expel feces, when his bowels are constipated. The lower portion of the rec-tum, including the orifice of the anus, is then found more or less relaxed, the length of the middle portion diminished, and hence thrown into circular folds; while the upper portion approximates the lower. straining be continued, some of the folds of the middle portion appear at the orifice of the anns; and if in this state of the parts a finger he introduced, we can easily, owing to the diminution in length of the middle portion, feel the lower part of the upper portion, and even pass the finger into it, when it will in general be found to be more or less contracted.

It is evident, from what I have said, that if, from any circumstance, the relaxation of the orifice of the anus, and the decrease in length of the middle portion of the rectum. with the consequent wrinkling of its coats, and the approximation of its upper to its lower portion, be excited, and continued with pressure downwards, the folds of the middle portion of the gut will escape from the orifice of the and, producing the state called prolapses of the annes, and which, as it exists in its prdinary degree in infants, is represented in this drawing.

the lower portion of the upper division of lower orifice of its upper division will, in the rectum, and if the finger he passed into the same proportion, approximate the arms, this ring, it will experience more pressure and in time pass through it, and thus protagate did in the middle division, though due the state of parts, so far has the proless than in the lower. From these facts, lapse is concerned, which exists in the and from many others which I could add, child whose case we have been consi-

will always, in the first instance, he formed

- 184 ·

by folds of the middle division of the rectum; and that if the discass increase, more
or less of the upper division, and inhiequently of the higher portions of the jubbs; p
tinal track, will be layerted, unless it helppens, ar accurred in the present instance, a
and as is pretty uniformly the court of a
lawys, when the invarion or accurates in
the rectam, that there exists, at the line of r
inversion, a spasmodic, or a personnelly
constructed stricture; and, under such circumstances, an increase of inversion cannot
take place beyond the seat of stricture, without the greatest difficulty, or perhaps not
at all.

It is also evident, in the first place, that in every case of prolapsus, where a stricture exists, as there is thereby more or less resistance offered to the escape of the contents of the bowels, those contents will be retarded above the narrow portion, and by their pressure will cause that dilatation of the gut, higher than the stricture, which was observed in this child, In the second place, that every case of directors, whether spatmodic or organic, in the upper division of the rectum, must become a more or less powerful cause of prolapse, or, at least, of invagination to a certain extent, as the feculent contents of the bowels, not being able to pass, unless with difficulty, through the narrowed opening, the organs of expulsion will necessarily be excited to greater exertion, and thereby the contracted portion made to invaginate itself into the middle pottion, approximate the lower, as I have afreedy explained, and assist to drive the related middle portion before it, through the external orifice or anus.

It is not very difficult to account for the origin of the common and erroneous opimion, that relaxation is the cause of prorus ani. You are aware, that in the case of the infant which we are considering, the muscles upon which the closure and support of the rectum in a natural state deend, were in an elongated and very relaxed condition, and nothing would be more natural than for an observer, who confined his attention to this state, to consider it the cause of the prolapse; but it only requires that you should watch the origin and progreat of this disease throughout the whole rectum, to be convinced, that this state of relaxation is the consequence of the pro-lapse, and not its cause. In fact, a prolapse egold not arise from such a cause. If it could, is ought to occur whenever the re-taining muscles are in a state of relaxation; but it is well known that, in cases of para-plegts, where these muscles are without any tone, prolapeus does not ensue at least from that cause.

When you need the observations of seven-bosome daily mer authors, but particularly those of Mr. facevin connect working. It. face, and Mr. Howship, more and more and

tion of the has attriexistion of the instead of to a et, and a necesof the organs of te appears to suppose a peculiar conformation in the least and direction or an amount in the least whome there arises a disth and direction of the large the upper part of the rectum to both of the recent in the recent in the recent in the recent in the first gentlemen's papers, you will find the recent in the Med. Chir. Trates, and Mr. Barlo's in the Med. Chir. Trates, and Mr. Barlo's in the Med. Gazette. It is a first more remarkable that Mr. Howship; and the facts which he has recorded in his work on the diseases of the intestines, did not form the opinions respecting prolapse which I have developed. He seems to be aware of the connection of structure with invagination or introsusception, and of the necessity of attending to the former, when we are endeavouring to cure the latter. He has also actually described a case of prolapsus ani, in which he found, after death, the upper part of the rectunt contracted, and the lower dilated; but the prepossessions of his mind, instead of leading him to what seems to me to be the proper use of the fact, made him view the contracted portion of the intestine as the healthy portion, and the relaxed alone as the diseased part. I would however recommend you to read Mr. Howship's work and judge for yourselves.

In short, in every case of prolapsus, your first inquiry should have for its object the source of that intestinal irritation, which, by exciting efforts of expulsion, has been the true source of the prolapse; and the cause which in nine cases out of ten produres prolapsus in children will be so obvious that it cannot be mistaken, if attention be paid to the origin of the disease, and its accommanying symptoms. It is a state of disorder of the whole organs, and this likely to the proin one way, but in several. become morbid, their impre testinal surface readless it levis creases the saormal acti morbid discharges of cites to a still more di tion. Hence the

which never f tractions may of sections confid cases the upper oftener morbidly cob part of the canal, and morbid appearance in any the intestinal tract, this pos tum will be found contra responding part of the colon

Picture, then, to yourselves a child whose entire intestinal surface is in a morbid state : whose intestinal secretions are companiently the treatment of diseases of the digestive also in a morbid state, whose sigmost feature organs. The general principles must be of the colon is irritable, and the hard large upper known to you, and their particular applicaalso in a morbid state, whose significance of the colon is irritable, as the place of the colon is irritable, as the place upper like of the colon is irritable, as the place upper like of the colon is irritable, as the place upper like of the colon is irritable, as the place upper like of the colon is irritable, as the place of the colon is irritable, as the colon irritable, as occurrence, and a state of the abdominal viscers which, in ninoteen instances out of twenty, precedes and accompanies infantile directed to the state of the gut. The obprolapsus ani. What must occur in such a case? On one hand, the bowels are mor- hand the morbid irritability and spasmodic hidly sensitive, and their merbid contents excite them to increased action. On the rectum, and on the other hand the relaxaother hand there is an increase of contraction of the upper portion of the rectum, and, at the same time, increase of effort of the organs of expulsion. This effort produces an involuntary relaxation of the parts about the anus, an invagination of the upper division of the rectum in the middle, and its approximation to the lower; a wrinkled state of the middle portion of the gut, and its subsequent protrusion through the orifice of the anus; while the contracted or spasmed state of the upper division of the rectum continuing, and the muscles driving on the contents of the intestines, a dilatation of the part above the strictured portion takes place. The stricture, which was only spasmo-dic, becomes, from a continuance of the disease, organio; and the state is sooner or later reduced which you see in this specimenin a morbid state of the of the intestinal tract, and of its out part by diarrhosa, cure of the colou. er portion of the aupervenes an division of the e orthog of the This is gonothe disease ex-

which have for their object the expulsion of in these, the spannedic contraction of the december posterior is followed by expulse contraction, purging, and by propose spanned contract and by alcoration of the parts of the intertions of the whole standard fract, a shade times will higher up, which jeed either to fatal ennis, or, as in the present case, to fecuon into the abdominal cavity, and

> pathology of prelapsus ani. not tell you that, when the ex of a disease is known, the prinn which its cure is to be attempted at. As the prelapsus of infants results from a morbid state of the abdominal visocra in general, and of the intestinal tract in particular, our first object should be to restore them to health by such remedies as we know to have the effect of improving and the cor-their secretions and tranquillizing their increased. To enter on a detail of the mode of accomplishing these important objects would be to cuter on a dissertation on last year. Independent, however, of this general treatment, our attention must be ject of this attention is to remove on one contraction of the upper division of the tion of its lower and middle portions. From what I have said, you know that if the disease be recent, we shall, for the most part, have simply a spasmed state, and consequent narrowing of the upper division, with a triffing relaxation of the lower; but if the disease be of very long standing, we shall find above, a greater or less degree of pr-ganic contraction and thickening, probably with ulceration and below serious relaxation. Now, it is in vain to attempt the cure of the relaxed parts, until that of the irritable parts is accomplished. How, therefore, are we to proceed to obtain the former chicot? The medical treatment of the morisid state of the digestive organs will assist much. But, this will not, in general, be sufficient; at least its influence will be slow : we must also act on the part locally. In the first place we must keep the partion of the larg intestine above the upper division of the rectum, as empty as possible; for, whenever there is any accumulation in it, irritation of the structured portion of the gut is the consequence, atraining ensues, the strictured nortion exists, and the portion above becoming dilated, the mischief is increased. condly, we must alter the morbid sensibility of the affected surfaces. The first object is to be obtained by thipwing up at regular in-tervals entellient injections, taking care that they pees beyond the narrowed portion; and for this purpose, it will sometimes be neces

sary to use an unusually long pipe, or a gum-in, at regular intervals, smellicut injections, clastic tube. To accomplish the materials to wash out the bowel above the restracted clastic tube. To accomplish the statist ob- to mask out the bowel above the contracted ject, I have experienced great assistance or spanned portion. from the cautious use of a beugie; but, par-ticularly, from the application of the nitrale of silver. By this remedy, I have suce in curing rapidly very severe cases of pro-lapse. The mode of applying this substance must vary in different instances. I expect that in the course of this session you will have frequent opportunities of seeing it used. The principle is, to act on the part with it as you would do on any other surface with the same application, when your object is to alter its morbid action. Sometimes I have rubbed the orifice of the narrowed portion with the solid nitrate, sometimes I have passed into the upper portion of the rectum, lint, impregnated with the solution, made in the proportion of fifteen grains to an ounce of distilled water. In all these modes of using the remedy, the lower portions of the gut are more or less acted on, and this I deem necessary, but I do not consider that it is sufficient to act on these portions only; the action of the nitrate must extend to the lining membrane of the upper division of the rectum.

After the digestive organs have been got into an improved state, and after the parts have been so far tranquillized that there is no difficulty in retaining the bowel in its proper situation, you may commence the employment of tonics or astringents if necessary, to improve the state of the lower and middle portions of the rectum. But I have generally found that even for this purpose the nitrate of silver is the best remedy, as far as local applications are concerned.

I have further to add, that the state of prolapsus ani never, perhaps, comes on without giving, for a long time, warning of its approach; and if attention be paid to these warning symptoms, much trouble may be saved. They consist in attacks of irritability of the bowels, with intervals of ease. The child's bowels will remain, for two or three days, confined, then a purging will come on, by which the retained matter is evacuated, and thus the parts are for a time tranquillized, to be again disturbed, after the accumulation has again taken place. In fritable state of the upper division of the rectum, combined with more or less derangement of the whole of the digestive organs, including the hepatic and urinary secretions; and in passing the finger up the anns, the upper portion of the rectum will often feel preternaturally contracted, or will form a sort of annulus above the pouch or middle portion. When such a case of disease occurs, repair the health of the diges-five organs, principally by attention to diet, "its, exercise, and clothing, and keep up a respect from ordinary. I regular state of bowels, not so much by the anus than in the situation use of purgative medicine, as by throwing bowels in which in the situation.

To repeat prolapses and in children originates in disease of the digestive organs, which draws on in its train a spasmed state, or irregular constant, but particularly of the upper strategy of the rectum. From this there remains difficulty in the escape of the feedlent matter; consequent necessity of straining at the consequent necessity of the continue of the rectum to the lower; a wrinkling of the folds of the middle portion; an escape of those folds through the external orifice; a relaxation or loss of tone in that orifice; a subsequent dilatation of the large intestines immediately above the upper division of the rectum, which has now become the seat of organic disease, with permanent stricture. Subsequently, ulceration of the lining membrane of the large intestines, but particularly of the sigmoid flexure of the colon, with great marasmus, ensues; and lastly, an escape of the feculent matter of the bowels into the abdomen, and consequent death. To cure, -improve the general state of the digestive organs, remove the local contraction and irritability of the upper portion of the rectum, and subsequently give tone and firmness to the middle and lower portions, thus terminating our treatment with the use of remedies with which practitioners too generally commence.

Were it necessary, I could adduce a vast number of facts to corroborate the views I have now unfolded. This would, however, carry me farther than my object at present, which is merely a clinical review of the case in question. Let me, however, recommend you to direct your attention to the subject, or hear it in mind, when you are reading on diseases of the rectum; and you will not fail to be more and more convinced, every step you advance, that what I have brought forward is the true pathology of this frequent and often very troublesome disease.

Whenever in appearability occurs I will develop my mode of treating the production ani of adults also, with the nitrale of all and the application of this remedy to usees of prolapse or introduception of highe portions of the intestinal canel which as pear at the amus, and which differ, as I have already informed you, in no other respect from ordinary probable

ST. THOMAS'S HOSPITAL

POMITING WITH BY

DELIVERED IN THE SE BY DEL

GENTLEMEN,—At the close of my last lecture (LANCET, No. 543, mage 451), I alluded to a case of invisation of the stomach, which I designated sentifus cust hysteria, and I will now read the statement of the case taken down by the clinical clerk directly after the patient's admission.

Jane Simpson, aged 22, a servant, was admitted into the hospital on the 20th of August last. She states that she had searlet fever two years ago, and has been "abort-winded" ever since. About sixteen months ago, without any apparent came, she was suddenly attacked with vonsiting, soon after taking a meal. From that kine she has vomited regularly every day. At first she vomited but once a day, then twice, and now she vomits in less than ten minutes after, or even in the act of, taking fluid. She feels very thirsty; her stomach generally retains solids, but never fluids. There is great heat in the stomach, the abdomen is very tender on pressure, the tongue slightly coated, edges rather red; the bowels have generally been costive; there is some psin in the head; pulse 102, and small. She menstruates regularly. There is, at the same time, a white discharge from the vagina, - some lencorrhœa.

Upon examining into this tenderness of the abdomen, finding that there certainly was some tenderness there, though no external heat was present, I thought it right to apply twenty leeches to the epigastrium, and to order half an ounce of castor oil every other day, and one minim of creosote every six hours, in a small quantity of mucilage and water. At first this dose of creosote was not sufficient. Next day, the 21st, she still vomited after taking food, and, therefore, in the evening the dose was increased to two minima, but still was not sufficient. It

therefore increased to three minims. which these was quite sufficient. She did-of which after taking food, and she centi-led free from vessiting from that the lime for publishmake period. Still, hereyous, shere was the tendormers, but it extended over the whole of the abdomen and thorax, and, therefore. That no doubt that it was merely that the property of the senting and thorax and thorax and the senting that the senting and the senting that the senting the senting the senting that the senting the senting the senting that the senting that the senting that the senting that the senting the

The state of the s

Make her in any respect antiphing initially.

Make her in any respect and there having being an oventiting from the date of the land being an oventity and any directed to take the mediant was directed to take the mediant wa regart, also was directed to take the medi-ciae anly twice a day. I should tell you that there was no emaciation. She was in

tolerably good condition.
On the 1st of September, having been free from vomiting since the 22nd of August, I ordered her to take a scruple of carbonate of sods, as the complained of scidity of the stomach, and ten grains of carbonate of smmonia, twice a day, with an ounce and a half of the infusion of cascarilla back. I left town at this period, and the appears to have gone on tolerably well, under this plan of treatment, from the 1st of September to about the 19th, when vomiting again returned, and Dr. Bunron kindly saw her for me, and he, viewing the case as I had viewed it, no doubt, -as one in which it was best to use caution,-also applied sixteen leeches to the epigastrium, and ordered her two minims of hydrocyanic acid, with a drachm of syrupus papaveris, every six hours, out of the mistura olei oliva. For three or four days this had the effect of lessening the irritability of the stomach to some extent, but on the 25th she again vomited, her pulse became 100, and small, and the dose of the hydrocyanic acid was increased to three minims.

I returned on the 2nd of October, and found the report stating that she had vomited every day since the 29th, and that she felt a dragging sensation after esting; tongue still was red, the epigastrium tender, the bowels confined, and the felt thirsty; pulse 102, and small. Not attaching any importance to the tenderness over the epigastric region, as no external heat was present, I directed that the other medicines should be laid saide, and that she should take two minims of creosote, in the mucilage, every six hours; and two grains of calonel, and sight grains of compound ex-tract of colocynth, every other night, at hed-time, as her bowels were confined. She vomited the first dose of croosote, and then ceased to vomit; her tongue became less red. her stomach less invitable, and she had less nauses, but she still complained of uneasi-ness in the epigastrium; and more perhaps to source her mind than anything cise, for I had discovered that she was exceedingly hysterical, I ordered a mustard cataplages to be applied over the region of the stomach. The creesote was persevered in. By the 9th of October her toughe had become meanly natural, but sa the still complained of loss of appetite, I did not hesitate to continue two minims of creceote three times a day, and to order two grains of the suighate of quinine with each dose of the organite Under this treatment she totally opased to who saw nothing in it but what was hysterical. I examined her chest myself, accurately, with the stuthoscope, and could discover no disease for the lungs. In fact the whole of her affections were hysterical.

Well, you saw that the creosote relieved the vomiting and the irritable stomach in the first instance, remaining well for some time, under the administration of the carbonates of ammonia and sods, and the carcarilla infusion; but when she had taken there for a formight or three weeks, the vomiting returned and was not allayed by hydrocyanic acid, though it was again arrested by the creosote; and eventually the stomach recovered its power by combining the crossote with a little sulphate of quinine.

Now, as regards the advantage derived in this case from creosote, which you know is a remedy that has not been very long introduced into practice, my late colleague REMARKS ON THE PROPOSITIONS OF MR. Dr. Elliotson being one of the carliest to Yearman.—Scale of REMUNERATION. try its powers. At the same time that Dr. Elliorson was using it, I also was administering it in the hospital; indeed I believe I was the first who brought it to this instiwas the first who drought agree with the opinion he has expressed in his paper in juxtaposition of Mr. Yeatman's and my the Medica-Chiruryical Transactions, that letter in The Lancer of Jan. 2nd. I trust creasone is often of considerable value in that they may induce a thorough sifting of allaying irritability of the stomach, when the arguments for either scheme; and though sue of that viscus. I do not, perhaps, quite agree with him as regards its efficiency in every such case. I think it highly useful in simple irritability of the stormers, but still I am quite certain that, like all other remedies, it does occasionally fail. I am disposed on the whole to say, that creosote is outilled to hold the same rank in the materia medica, as a remedy in irritable conditions of the stomach, free from all inflammatory siction, as does the oxide of bismuth. Indeed, after having used it from the first bested of its being known in this comity, I
windly lay that I have not been able to its
more with creatests in tritable conditions of any previous, for it would that the stometh, than I have with the trade of our many a testable substitute for a practic-

vomit, and lost all irritability of the stoinach, blamuth. I have used crossote and suchbuight she complained of filtediseas, for which I ordered ave grains of the galaxinum pill with each dose of the guituhe, continue and such conditions of the stoesach. I have used crossote and such which I ordered ave grains of the galaxinum pill with each dose of the guituhe, continue, the same time the guituhe, continue, and the same time the support of occasional hysterial attacks. I should mention to you that during this period she had frequently complained of cough, and site herself entering this period she had frequently complained of cough, and site herself entering the grain of cough, and site herself entering the grain of the stomach. All of your understand grain of the stomach. The cough, as I understood from one of our pupils, who knew something about her, had pusited a little the medical gentleman under whose care she had previously been, and whose we nothing in it but what was hyster tried it. I tried it in a case in Luke's Ward. tried it. I tried it in a case in Luke's Ward. in an old man who, beyond question, had organic disease, most probably attended with an ulcerative condition of a portion of the stomach. In that case a few doses of crossore produced vomiting, which the hydrocyanic sold immediately stopped, and for a time so far allayed the irritability of the stherach, as to enable him to take such diet as the remaining power of the stomach could digest. I need not take up more of your time on this subject, but will proceed to another case, - which, though an instance of chronic disease, presented features of considerable interest.

PAROCHIAL MEDICAL ATTENDANCE.

To the Editor of THE LANCET.

Sin,-1 could hardly have hoped for so allaying irritationary of the automatory of the profession action, and that you cannot but do injury by exhibiting crecotor whenever there is any ching like inflammation in the mucous tisting like inflammation in the mucous tistion on his dwn propositions, and on the desired with the profession action, and that the profession action, and that you cannot be seen the profession action, and that you cannot be seen the profession action, and that you cannot but do injury by exhibiting crecious of replying to one or two of Mr. Yestman's observations, and that you cannot but do injury by exhibiting crecious of replying to one or two of Mr. Yestman's observations, both on his dwn propositions, and that you cannot but do injury by exhibiting crecious of replying to system of a payment for each case of illreas; as well as to put you in farther pus-session of the details of the latter mode of remuneration, as proposed by myself.

With regard to Mr. Yestman's See prop sition, I beg to refer your readers the objections stated in the second solus letter, which I humbly conceive are acuta-eive, as to the difficulty attending the cal-culation of this mode of payment.

timer, who may have medicated, and have become inestinguished for, his duties.

Ills third, proposition is quite in which streets into with my own ylawi, as to the projectity of including swirt thing (with a single street ino., viz., valcination) health missinguished; for it, according to my itan; the transition in the region of the relieving.

But upon his fourth project with the medical officers in this intermediate in the region of the countrilized.

But upon his fourth project with the medical officers in this intermediate in this intermediate in this intermediate in this intermediate in the region of the same class the justice or projects of the medical officers in the intermediate in the region of the same class indeed Mr. Y. elsewhere allows, "that the relicious officers can know institute of the project for the benevolence, persecutiving officers can know institute of the project for the benevolence, persecutiving officers can know institute of the project for the benevolence, persecutiving officers can know institute of the project for the benevolence, persecutivity and helples portion of the countrilized.

Permit me now to show the practicalility with which led has for calculating a soale of remaineration on professional person is to decide on the paprofessional person is to decide on the pa-; the principles I have already laid down. tient's need of assistance) " might have been restored if duly supplied with the medicines and attendance in the earlier stages of the disease.

This early attention can, therefore, only be ensured by an immediate and unrestrained application to the medical officers, and the plan which I have suggested, to prevent the parish and the medical men being burdened with applicants who have no claim on parochial relief, is quite a sufficient check on all parties, viz., that the Board of Guardians should investigate the weekly list of patients presented to them by the medical officer, and declare that the medical relief afforded to those individuals who do not belong strictly to the class of paupers, is merely by way of loan; the regular payments for such cases being recoverable from the patients accord-ing to the provisions of the Poor-Law Amendment Act, or similar provisions to be made for this special purpose. The patient to whom such aid is lent, should be entitled to medicines and attendance for one entire week (at least) from the first application to the surgeon. By this means not only are the parish and the medical officer protected from loss, but, in the interval, prompt attendance is provided for the sick

I have considered Mr. Yeatman's plan attentively, and am unable to discover how his scale of remuneration could be applied, if, as he proposes in his last letter, "the expense of drags were defrayed by parlates and unless." He must turely contemplate some redection of his beale, when he recombended this separate parochial payment

r meddines.

With regard to his proposal, however table in practicable it might prove in large towns, it would, I feel convinced, be quite the contrary in agricultural districts there can be no depot for drugs, except the medical riter's own residence.

A payment for a case of illness must include two items of remuneration; -the first. a payment for drugs, &c. &c.; the becond, a payment for drugs, ac. ac.; the second, for the time, skill, and trouble of the surgeon. The first may be readily estimated by a reference to hospitals and dispensaries ac. The Rev. C. Oxendon, of Bishopshourne, has drawn up, with great industry, skill, and success, a "Buffifical Report of the Principal Provincial Hospitals in Engineering Provincial Hospitals in Engineering land." The average cost of each patient in those institutions will be found in this very valuable work; I have deduced the following calculation from it :-

The total number of patients treated during one year in twenty-seven hospitals (including all except a few small and recently established infirmaries) was 90,426, of which 23,180 were in-patients, and 67,246 outpatients. The total expense of these in drugs, leeches, wine, spirits, surgical instruments, &c., was 17,9691, or about 3s. 111d. per head; - in drugs and leeches only, 11,0444, or 2s. 51d. per head. The first of these sums includes more than the parishsurgeon has to supply his patients with : the second, less; we may suppose the intermediate sum of 3s. to be nearer the mark; but we must admit, from Mr. Oxendon's impartial statement, that the expenditure in drugs in some of the hospitals has been uselessly extravagant.

I have further examined afteen annual reports of some of the principal dispensaries in England, both charitable and selfsupporting, which give a total namber of patients of 26,708; and an expenditure in drugs of 1561L, or about 1s. 3d. a head.

The Rev.C.Oxendon elsewhere says, "The medical expenses of an hospital in-matient : quite the contrary in agricultural districts patient during the same time. So agains, with a scattered population; in these cases they can be no depot for drugs, except the agricultural way hose-epatients will be more they can be no depot for drugs, except the agricultural way that those who attend personally at the dispensary. I consider 1s. 6d. per Mr. Yoshian's objections to "a payment the dispensary. I consider 1s. 6d. per millent" or "per case," apply only to for an in or home patient."

A respectable druggist in Southampton other hand, where there are very few paramples medicines to the patients of charitable dispensaries at 4s. per head; another in Blackfrium, London, at 2s. od. per Again, the circumstance of distance from

But another valuable fact may be taken from St. Mary's parish, Nottingham. In the parochial dispensary, in which the num-ber of patients annually treated (on an average of seven years, ending March 1825) was 2006, and the average annual expense in drugs &c. per head being about 1s. 5d. Taking, therefore, these several averages

as guides, we may reasonably and fairly conclude that a payment of from 2s. to 3s. per head would defray the cost of drug. When the number of patients is great, I have no doubt that 2s. would be sufficient; while, if small, 3s. would be required.

The second item of remuneration, viz. the time, skill, and trouble of the medical attendant, is not so easily estimated, as, of course, it is more a matter of opinion. It cannot and ought not to be expected, that parochial remoneration should, by any means, be equivalent to the value of professional services. Medical men must look for their incomes to the higher and middle classes of society, and can only claim of loss in their attendance on the poor.

Influenced by these notions, I suggest that the lowest average payment for attendance solely, should be 1s. for each case, and the number of patients in geometrical, a this only where there are very numerous much more reasonable as well as more patients comprised within a small space, and correct variation than that of Mr. Yeatman's close at hand to the medical officer; on the scale.

Again, the circumstance of distance from . in, the circumstance and phinly partitled adjust officer, which in phinly partitle described as him conricultural districts entails on b alderably more labour and expense, re a distinct and uniform obarge, not o the rossess just exactioned, but as a permissry check as gardent appointing medical officers situated respective and inaccessibly with research to this substances. gard to

For the distance appropries an additional fourpence are mile for each patient residing at a distance from the medical officer, whether actually visited by him or not. This arrangement would not be open to the objection properly urged by Mr. Yeatman

against a charge for each journey.

Such being the data of my calculation, deduced not only from the average estimates already mentioned, but from a comparison of many perochial salaries, I recommend the annexed scale, in which it will be seen that the lowest charge, 3s., includes, as before stated, the cost of drugs 2s., and of attendance le., while the highest rate of the scale comprises the cost of druge 3s.; attendance 3s.; and distance above five miles (or the community an exemption from absolute within six) at 4d. per mile, 1s. 8d.: in all 7s. 8d.

The intermediate charges of the scale

increase in arithmetical progression, and

SCALE for calculating the Remuneration for Medico-Parochial Services.

Distance of Patients from the Medical Officers being within		Number of Cases of Sickness and Accident attended in each Parish dering One Year, being														
		25		50		100		200		400		800		1600		
- A	1	Mile	6	d. 0	a. 5	d. 6		4.	4.	đ. 6	4	d. 0	3		3	d. 0
2.1	2	Miles	6	4	5	10	5	4	4	10	4	4	3	10	3	4
	3	Miles	6	8	6	2	5	8	5	2	4	8	4	2	3	8
	4	Miles	7	0	6	6	6	0	5	6	5	0	, 4	6	120	•
- /~	5	Miles	7	4	6	10	6	4	-5	10 /	5	4	4.4	10	22 W4#	de.
Å.	6	Miles	7	8	7	2	6	8	6	2	5	8		2		

Exemple.—If the total number of cases hetween any of the numbers mentions useded during one year in any parish be the head of the scale, the payment is.

If the payment for each of those occurring should be altered proportionally; thus a medical officer had attended 150 cases. be 4s. within two miles 4s. 4d., within three miles 4e. 8d., within four miles 5e., and so on.

If the number of cases be intermedia

f., payments would be 4s. 9d., 5s. 1d., 5s. 8d., es 5s., 5s., 5s. 1d., and 6s., 6d., according to the distance requestingly. The subdivision of the scale negatively to request the scale negative.

One column of the above scale, or some infermediate rate of sayment suited for each parish, should be agreed on at the beginning of the year (perhaps according to the number of cases attended during the previous year); otherwise either party concerned might, by fraudulent management, increase or reduce the sun total paid for the same amount of labour at the said of the year.

Egery distinct and different case of ill-

Egery distinct and different case of illness, or accident, in the case individual, however close in saccossipa, should be charged; but to private any maker conduct on the part of the medical officer, a relapse of the same disorder occurring within one month from the date of discharge should be considered as part of the former illness.

There should be no extras, except for midwifery, trusses, and vaccination; I think I am expressing the opinion of a majority of medical men in proposing that the ordinary run of pauper midwifery cases should be managed by a female midwife; a medical practitioner attending only when called on by her. This will not only be a saving to parishes, but a relief to the profession. The charge should not be less than one guisses, with an additional allowance for mileage. Vaccination might be charged at 1s. 6d. per head, and trusses at cost price.

No practitioner should be allowed to attend paupers distant more than six miles, unless he be the nearest eligible medical resident to those paupers; when a further charge of 4d. should be made for every additional mile in each case; nor should any one be permitted to undertake the entire care of a parish or parishes, which, during the previous year, have furnished a total of above 1000 cases; nor any firm of medical men more than 1600 cases.

There is one obvious advantage in the proposed remuneration, viz., that as it provides for two clearly defined items of expenditure, they might be separated, if desired, and so afford a facility to parishes for supplying their own drugs (which, although recommended by Mr. Yestman, could not he satisfactorily effected on his plan); for instance,-deducting 3s. for medicines from each of the payments in the first column, for 25 cases; 2s. 10d. from each of the payments for 50 cases; 2s. 8d. from each of the payments for 100; 2s. 6d. from the payments for 200; 2s. 4d. from the payments for 400; 2c. 2d. from the payments for 800; and 2s. from the payments for 1600; the remainder will show exactly the sums which should be awarded to any surgeon who missing indertake the care of the poor, with-

material part of my scheme unexplained, but shall be happy, with your permission, to enswer any questions or observations it may elicit. I remain, your obedient servant, cas. 12, 1866.

THE LANCET.

London, Saturday, January 23, 1836.

THERE can be but one opinion amongs! honest and intelligent men relative to the course which the Ministers should pursue is founding the new University, and that course is indicated with sufficient clearnes: by simply recommending that they should act upon sound principles of popular government, rather than receive with approbation the noxious suggestions and schemes of the rump of the old corruptionists. The confidence which we repose in the Ministry leads us to suspect that the CHANCELLOR of the Excusousa did good-naturedly comply with an urgent request that he would receive the report made to him by the College of Physicians, and one of the Councillors of the College of Surgeons, concerning the medical department of the projected new institution; and it would appear that some dozens of simpletons have been deceived by the ruse which was so admirably played off upon them by the CHANCELLOR. of the ExcHEQUER. The manœuvring wrong-heads were guilty of the folly of believing that the reception of the report by the CHANCELLOR would be synonymous with its adoption by that Government functionary. It is clear enough that these creatures, who are so fast sinking into professional obscurity, will catch at any straw, however slender it may be, in the hope of maintaining a little while longer even their present degraded position. No sooner, therefore, had the CHANCELLOR of the Ex-CHEQUEE allowed three or four of the old corruptionists to be named as the individuals who should frame a plan for the medical department of the New University, than did the halls of the old Colleges resound with every possible expression of satisfaction and delight.

Every person who has had any experi-

which the corruptionists push their interests benevolent and high-missed occupation in in the government offices, must approve of which they are necessarily engaged assungst ... the measure to which Mr. Spring Rick all classes of the community, they unsection an resorted, in order to be ridded for a while from the entreaties of his termentors. But for any man to suppose that the CHANCEL-LOR of the Excurquen intended to adopt. bong fide, the scheme of the HALFORDIAN crew, is to cast upon that gentleman an imputation which it would be most unjust to the honour and intelligence of the minister to inflict upon him. The medical practitioners of England have not yet forgotten that it was to the head of the present Ministry that they were indebted for the success of Mr. WARBURTON'S motion for the appointment of a committee to inquire into the nature and extent of medical abuses. It will not be easy, therefore, to make those high-minded men believe that Ministers would subject themselves to the imputation of wantonly trifling with the feelings of the most useful and influential body of educated men in this country. Had Mr. Spaing Rice really conferred on SIR HENRY HALFORD, Sir B. BRODIE, Dr. ROGET, and Dr. CHAMBERS, the power of framing the arrangements for the medical department of the new university, he would have proved by that one act-whatever may be the extent of his classical and general attainments-that he was incompetent to exccute the task which had been confided to him by his colleagues, and, moreover, that he was blind to the faults, the prejudices, and the practices, of the parties in question, and possessed of no knowledge whatever of the claims which the medical practitioners of England are at this time forcing upon the attention of the legislature. But we tell the investigation, they are, in all probable in this empire are upwards of twenty thou- upon principles of acknowledged justice and

ence of the industry and pertinacity with and respectability, and, still more, from the influence over public opinion, which is paramount to that of the members of any other profession. It is not extraordinary, therefore, that their arguments, in any question, should receive the respectful and earnest attention of total Pouses of Parliament.

Now, it happens that the members of the medical body have no particular desire to see any new medical titles awarded, which are unconnected with the rights and immunities of legally-qualified practitioners. They necessarily view with caution and jealousy, the proposal to institute a metropolitan university, wherein degrees of medicine are to be granted, because they apprehend that it will only serve further to entangle the question of medical reform, and add to the confusion which already exists on the subject of medical qualifications. At the very outset of the University question, we deprecated any fresh meddling with medical affairs until the report of the Medical Committee of the House of Commons was placed before the Legislature. Not one-third of the esidence, the printing of which must necessarily precode the publication of the report, is yet before the profession; and we suspect that the Ministers of the Crown know little relative to the inquiry, further than that the evidence has proved that the entire system of medical government must be remodelled. That such a conviction exists in the minds of the Members of the Committee, Mr. Rick and his colleagues are, doubtless, sware; but with the particular points of the evidence, the striking facts of the boobies who have been deluded by the lity, totally unacquainted. Who, then, shall tact and discomment of the CHANCELLOR contend that the Ministers can safely are of the Excurences, that the medical reformers are now too strong to stand in fear medical institution? Even if we admit of any ministry. The medical practitioners that they resolve to advance in their work sand in number, and, from their intelligence liberality, will their want of acquaintance the state of the s

withathe defects and abuses of the old cor- | leagues. If Mr. Spains Ricz, however, be porations, may lead them to commit many in an endless network of perplexities. Yet, if they determine to proceed before the Members of the Medical Committee have had the opportunity of framing their report, and apply, in their emergency, to their foca -their inveterate and implemble focs-for advice and assistance, rather than to their stanch and steady friends, they will at once forfeit that respect which is now felt towards them, in a pre-eminent degree, by nineteen-twentieths of the medical practitioners of the United Kingdom.

But the conduct of the executive Government in the last session of Parliament, regarding the municipal corporations, was so distinguished for its liberality, that not a doubt can exist in the mind of any sane man, that the rotten medical corporations, in which the system of perpetual self-election is maintained, will be entirely and for ever overthrown, and that in founding the new university, no similar tyrannical and unjust power will be exercised by any set of individuals whatsoever. Neither the profession nor the public are in a state of mind to be trifled with on this subject. Hitherto the Ministers have proceeded in an honest, straightforward, culightened course of policy, and we call upon them, as they value their own honour and the best interests of the country, to recede with horror from the proffered assistance and embraces of the self-elected and sordid monopolists who have so long scourged and degraded the profession by their iniquitous conduct in the College of Physicians and the College of Surgeonit.

No idle report or loose rumour will induce the profession to believe that the Mito have described the cause which they already so ably supported, and we are rehensible character and description can

really desirous of obtaining for himself and serious and fatal errors, and involve them his official associates the unextinguishable haired, and the profound contempt, of ninetynine hundredths of the medical practitioners of Great Britain and Ireland, he will call to his aid Sir H. HALFORD, Sir B. BRODIE, Dr. Roger, and Dr. CHAMBERS, and adopt as his own the scheme of those gentlemen for governing the medical departments of the new university. The CHANCELLOR of the Excurquen might then take his leave of the question of medical politics. At any rate his views on that subject would never afterwards carry with them the slightest interest, except to the most incurable, ignorant, and sordid of the plundering monopolists.

A EXPORT of the meeting of medical students of this metropolis, which was held in the great room of the Crown and Anchor Tavern on Monday evening, will be found in another part of this week's LANCET. It was computed that from first to last there were present on that occasion 1500 medical gentlemen, nearly the whole of whom were students. A more respectable assembly, or a more interesting one, was never seen in this metropolis, and considering the degree of excitement which prevailed in the minds of the gentlemen present, -all of them labouring under the impression that they had been grossly injured and insulted at Apothecarles' Hall in the person of one of their body,-the decorum and excellent order which prevailed, evidenced the importance that was attached by the assembly to the subjects which were brought under discussion. The declaration which was then made by the medical students of London, in favour of a public examination of candidates for medical honours, is, beyond all question, the most striking fact in favour of ared that nothing but facts of the most throwing open those Halls and Colleges where medical degrees and licenses are connee the profession to withhold their con- ferred, that has ever been submitted to the refron Land Manaobana and his col- attention of the legislature and the sublic

In short, such a declaration must annihilate letters contain, and we also inform what the accret system, and establish in its stead, that we have been requested to state that no petition was forwarded to the govern-

The bold and manly bearing of the medical students of the metropolis, in thus demanding that their attainments may be fairly and openly scrutinized, must obtain for them the respect and admiration of every enlightened member of the profession. The chairman of the meeting, Mr. MEADE, conducted the business of the evening with judgment and ability, and it was gratifying to observe the deep interest which Mr. CARPUR, with his whitened locks, still manifested in promoting the welfare of medical pupils. But what attendance was there of the physicians and surgeons of the "recognised" hospitals of the metropolis? What attendance was there of those gentlemen who utter such a profusion of bonied and friendly professions in their introductory discourses on the 1st of October, - the ticket-selling, fee-catching day? What attendance was there of those ever sincere friends of medical students? Oh the number is easily counted. Mr. Liston, of the London University, was the only hospital surgeon in London who supported the cause of the students by his appearance on the platform, and it rejoices us to be enabled to state that that distinguished surgeon received, as the just reward of his spirit and liberality on this occasion, the unanimous and hearty greetings of the entire assembly.

The views and purposes of the meeting will be found so fully expressed in the account furnished by our reporter, that we content ourselves this week with referring the profession for information and food for reflection on the highly important subject discussed, to that document.

IN giving insertion to the letter of Mesers. Carmicharl, Campron, and Colles, we take this opportunity of directing the attention of our highly respectable correspondent "Observator," to the contradictions of his stayment which these

letters contain, and we also inform him that we have been requested to state that no petition was forwarded to the government by the "Sisters of Charity" on hebalf of Mr. Franall, and that the remarks relative to the interference of those ladies in the election, are entirely unfounded. We have also a separate letter from Mr. Carmicharl, without room to insert it this week.

In a clinical lecture which was delivered a short time since by Sir CHARLES BELL at the Middlesex Hospital, some remarks were made on the subject of reporting clinical lectures in the medical journals, which demand from us an especial notice, and they shall receive it. Without intending to offer to this distinguished gentleman the slightest offence, we would seriously advise him to turn the current of his thoughts to any quarter rather than that of the press, or be will stand a fair chance of entering " modern Athens" as a confirmed twaddler. Some men take pains to make themselves ridiculous. Sir CHARLES BELL is one of them. and on three or four occasions in that way, his attempts have been very successful.

GREAT MEETING

OF THE

MEDICAL STUDENTS OF LONDON,
AT THE CROWN AND ANCHOR TAVERN,
On Monday, Jan. 16, 1520,

TO PETITION PARLIAMENT
TO EFFECT AN ALTERATION IN THE
EXAMINATION OF CANDIDATES

MEDICAL LICENSES AND DEGREES,
AND TO FORM A

CENTRAL STUDENTS' ASSOCIATION.

Tau challenge forwarded by Mr. Thomas Surra to the Court of Examiners at Apothecaries' Hall, demanding a public mannagem in order to prove that his rejection by the Court on the previous Thursday and not determined in consequence of the information of a competency of the candidate, led to the formation of a committee of medical attactuate to determine what steps should be taken by the greet body of students in Lendon on the conductor of the candidate with the prior of the calculated and determine what steps should be taken by the greet body of students in Lendon on the conductor of the greet was engaged.

which they universally laboured in conse-| term the Examiner sneered, and so began quelics of the existing system of private ex- to decry the acquirements of the candidate. aminations at the medical boards. The He was then asked, how nitrogen got into committee, it appeared, resolved as non-the system? He replied, partly by the vening a public meeting of the students to take the subject into consideration, which was publicly advertised, and held on Monday evening last, at six o'clock, in the great room of the Crown and Ancier Tavern, where nearly the whole of the medical students in London were assembled.

The proceedings commenced by the unanimous nomination of Mr. WILLIAM MEADE, of King-Street, Southwark, to the Chair,

amid great cheering.

The CHAIRMAN then opened the business of the evening in the following statement: Gentlemen, you have been called here this night by advertisements, in which it was signified that a discussion on matters of vital importance to your future welfare and interests was to take place. It will be my duty on this occasion shortly to explain to you why it was desirous to hold a public meeting for this purpose. You are all aware that near Blackfriars Bridge there exists an institution which is called the Apothecaries' Hall of London; and you are also aware that many acts of injustice have been committed by that tyrannical body of monopolists. The characters of many of your professional brethren have at various times been destroyed by the unjust proceedings in that establishment, at the examinations of students, and the question now is, whether by an unity of moral force and an appeal for justice to the right quarter on your part, you will not, after this fresh instance of injustice, attempt to prevent a repetition of oppression on the part of the offending body. (Cheers.; Without, then, further preliminary remarks, I shall at once state to you the facts of the case. Within the last three years I have been occupied in the duties of a private teacher in London, and have become acquainted with instances of gross injustice to medical students by the Court of Examiners in Apothecaries' Hall. The details of the examinations would sufficiently testify this fact. I shall confine myself, however, to the act of injustice which has been the more immediate cause of this meeting. The gentleman who was rejected on Thursday week, was interrogated in the strangest manner. He was first shown a prescription in which camphor and marcurial ofniment were directed to be admired. He was asked, what was the use of the camphor? He said, it promoted the absorption of the mercury into the system. Industry inquiry was, how that was effected? He replied, by stimulating the lymphatics. He was then asked, did it act upon the absorbents? His reply was, that the lymphatics were the absorbents, and he also add castor oil to the enemata. "
mentioned that it was partly taken up by mouth?" was the inquiry. He sai
the process of endomore. As that executing because there was great sickness.

agency of respiration. The Examiner said, that there was as much given out as was taken into the lungs, therefore there could not be any taken in at all. He was then asked, did it obtain admittance in any other way? He mentioned, that it was taken in through the medium of the digestive apparatus, and said that some vegetables which are used as condiments contained a considerable quantity of nitrogen. He was asked, what these were? He replied, that they belonged to the natural order of crucifere. He was told to name them; and he mentioned the different kinds of mustard, horse-radish, broccoli, and cabbage. the Examiner said, contemptuously, "Tailor's cabbage, 1 suppose." (Cries of "Shame, shame.") The Examiner soon after inquired, what was the ultimate composition of the muscles? He mentioned carbon, oxygen, nitrogen, and hydrogen; whereupon he was asked in a gruff and surly voice, whether nitrogen, therefore, did not get into the system in beef and mutton? (Much laughter. Then he was asked, what was the state of the bowels in diabetes? to which he replied, that they were irregular in their " Constipated, Sir," said the action. Examiner, "constipated; how can the bowels be irregular when so much fluid passes off from the system by the kidneys?" Great Laughter.) I suppose the worthy examiner considers that much fluid is essential to wash out the bowels. Mackintosh, Gregory, and Martinet, state, the two first, that the bowels are irregular in diabetes, and the latter that they are irregular, but generally constipated. The student was then asked what was the state of the pulse in nephritis, to which he answered " Quick and hard," which the Examiner instantly contradicted in the most abrupt and rough manner, by "Quick and full, Sir." (Cries of " Shame, shame.") Mackintosh and Gregory state that the pulse is quick and hard. Marshall Hall does not notice the state of the pulse in nephritis. He was then asked what was the treatment of intermittent fever, and he said that before the accession he would give an emetic, and mentioned the treatment recommended by Dr. Mackintosh, and which is now very generally adopted, namely, bleeding in the cold stage of intermittents. The candidate was forthwith asked, in a tone of astonishment, would he bleed? He replied that he had heard that practice strongly recommended, and should be inclined to adopt it. He was presently afterwards asked what purge he would give in nephritis, he said he would add castor oil to the enemata. "By the mouth?" was the inquiry. He said, No.

then, would he give by the mouth? He said the part of its Examiners. (Hear, heer, heer.) two or three grains of calomel. "No, Sir," the Examiner replied, "you should give a jorky of the Court, but he is not, surjetly said purge of ten grains of the extract of speaking rejected on any consists by a collogyath and five of calomel. (Issues) majority. An Examiner course is similar to the condition of the condit ignorance, captiousness, and unfairness, was the rejection of the candidate. There are numerous other points in this ex-amination, gontlemen, but I shall not speak further on I this evening. I hope I have mentioned sufficient to satisfy you, that the conduct of the Examiners on this occasion has been unjust. I promise you that the examination shall be published, supported by the very best authentication that can, under the circumstances, be given to it. Court of Examiners, without any means of appeal, so long will injustice continue to be perpetrated. When they improperly reject a cannot, Sir; the Act of Parliament does not law, to apply to the Legislature to give us at least good laws for examining bodies to fall back upon, with power of examining a second time, and public examinations (cheers); for, while they are private, you may be sure that when once a Board of Examiners has committed an act of injustice. they will not like to falsify their first decision by passing a man the second time. The second examination would, if possible, be more unfair than the first. In taking the chair to-night, gentlemen, I do trust and believe that your enemies, who are carefully watching your proceedings, will not have the power of saving that medical students cannot meet without occasioning some disturbance. (Cheers.) The Examiners of the Hall are now chuckling at the idea. that the students will commit themselves to-night, and that is the only ground they have for hoping to have the power of again doing you wrong. With quiet and becoming conduct, you must here protest against their injustice, and you will then succeed in your object. Your wrongs need discussion among yourselves, and the mode of redress-ing them will not be long unsuggested. Many are the men who have, in the course of years, been sacrificed to the injustice of this institution, men who have been fully competent to practice their profession, but who have left that Hall with aching hearts, not knowing where to hide their heads,-men who have been previously known to their fellow students and professional friends as able and well-qualified disgraced on account of some injustice on which I shall not explain

The student is said to be rejected by a for two or three inhances, hears what the candidate says, pursue him by some question which is persider to the Hall (cheering and laughter), walks away, and is succeeded perhaps by another Examiner, who walks by, shakes his head, and crieff "A had husiness," and the papil is rejected. The Act of Parliament contemplates that at least a majority of the Court should listen attentively to the examination, and not that two or three of them should walk to and fro by the table, putting peculiar questions, Such reckless unfairness can only receive and thus professing to form their opinions its reward by publicity. (Hear, hear.) I am on the talents and compotency of a man. I convinced, that so long as there is a private will tell you what is the mode of decision with one of these philosophical Examiners. He says, "When first a young man comes into the room we look in his face, and if candidate, and they are supplicated to give we see that he is clever, we expect so much another examination at once, they say—"We the more from him; but if we do not think he is clever, then we try whether he knows permit us to give you another examination." anything at all, or whether he can be of any Then it becomes our duty, if the Hall is use to society, and so help him on." (Great really so precise in its observance of the laughter.) Is an Examiner who judges according to physiognomies who he should sport with? is such a man as that fit to be an Examiner? (Cries of " No. no." It is too bad that the examinations should assume such a form as they do. There are four tables in the room; it is all a chance to which table a pupil is conducted, whether to Mr. Ridout's table, or some-body else's. Perhaps the other three tables are supplied by at least gentlemanly Examiners, if not very competent ones. (A cry of " Wheeler is as bad as Ridout.") Well, they are both very bad. (Laughter.) Now, of four students who may go in, three may pass through very well, but the one who falls to the lot of the fourth examiner, may, on no kind of principle that is good, fall a sacrifice to that accident, or to some private pique or spite, and have his character completely destroyed. The gentleman who has challenged the Hall to give him a public examination, had, before he went up, the full approbation of his lecturers and teachers to present himself, and he was considered perfectly competent to pass at the school to which he belonged. But there was evidently something premeditated against him, and whether by chance or design he fell into the jaws of Mr. Ridout. It is a fact that in the very middle of his examination, his indentures of apprenticeship, which had before been received, were brought into the room by Mr. Watson, who tapped him on the shoulder, and laid them on the table, when the Examiner took them up at that particular moment to inspect. There was candidates, who have gone from that Hall a reason for this extraordinary proceeding, to you now, b

If Alberta convincing proof that you have plate, and demand that they make it period no protection at the Hall against the most their duty to reform the present system undecoming and depressing acts on the part without delay. I remain, your obsof providing a remedy against the injustice dient servant,

of that body, and is protect, in future, the professional rights of the student. (Cheers.)

Mr. Parks, rose and said, —Mr. Chair-Resolutions having for their object these man and Gentlemen,—I am deputed by the purposes, will be proposed to you, and I am sure that you will hear with attention everything that is said to the point respecting them. As far as my endeavours can go there shall be a fair and impartial hearing points in question,—the examinations at the Ifall as at present conducted, and the best mode of protecting the medical students of London from injustice. (Hear, hear.) General politics we shall wholly avoid. I ask of you a calm, quiet, and dispassionate discussion, and let not the Examiners of the Hall, or any of your oppressors have reason to say to-morrow that this was merely a meet-ing of riotous students. That is what they want. It is their great hope that this will be a riotous meeting. "There will be a row," say they, "the students will depart, and then what care we. The students will then have no power, and their meeting won't affect us a bit." If your enemies choose to say what is untrue, why, we can't help that. But let them have no good ground for considering that after this meeting they will actually have more unjust power over you than ever. Deceive their wishes, gentle-men, by testimony that cannot be mistaken. (Loud cheers.) The following letter from Joseph Hume,

and received with very great applause :-" To the Chairman of the Meeting. Sir .-I request that you will state, if it should be necessary, to the meeting, that I should have attended, agreeably to the request contained in Mr. Paine's letter of the 16th, if I had not had a previous engagement which I cannot avoid. Be pleased also to state that I concur in the propriety of their making application to the Government for an immediate and thorough reform in the regulations and practices of the Examiners of the Apothecaries' Company, of the College of Surgeons, and of the College of Physicians. All require to be new cast, and some intelligible system adopted for the regulation of medical education, the granting of degrees, &c., and, above all, all examinations for degrees, diplomas, or liceuses, should be held in public. I hoped to have sten Mr. Warburton respecting his views for the next session. But although I know

200

Esq., M.P., was then read to the meeting,

"JOSEPH HUME.

Committee to propose to you the first resolution, and I can assure you that I feel more than an ordinary degree of pleasure in doing so. I feel that we are now about to try to obtain the redress of one of the greatafforded to every speaker who keeps to the est grievances that can befall a student. We do not meet in ignorance of the tyranny that has so long been exercised at Apothecaries' Hall, when it has suited the purposes or the whims of the Examiners. We know too well that many of the students who have been rejected there, were men who were far more deserving of holding scats in that Court than those men who really occupy them, and while those institutions which affect other classes of the community are undergoing reform, why should not the Apothecaries' Hall be also reformed? Men's minds have become more expanded, and their knowledge much greater, and I am sure it is not right that men who were educated nearly half a century ago, should have the power of sitting as an irresponsible and secret board of examiners, to exercise their power over students of the present day. (Cheers.) We know that very many men have gone into that Hall, who have devoted years to their profession, and who possessed high intellectual attainments, have been made to bow to the shrine of ignorance. (Cheers.) Why should not such an institution become the subject of reformation? But I am happy to know that the days of all close corporations are numbered (hear, hear); and I sincerely trust, that ere two more sessions of Parliament have closed, that the present corrupt body will be totally abolished. (Great cheers.) I hold in my hand a letter which I have received, since coming upon these hustings, from Mr. Warburton. (Some person here said, "That is politics.") A gentleman behind me says I am introducing politics. I say that this is not the fact; I will not touch upon any politics but medical politics, and those are the politics which we are expressly called upon to discuss. Mr. Warburton says that he should have felt much pleasure in joining this meeting this evening. (The same individual said "You mus'nt read it. It's politics. It is private. It is to the sta-dents. Cries every-where from the meeting of " Read, read.")

that he is most anxious to see a therough
"To Mr. Paine, Secretary to the Commitreform in the profession, yet if you wish for
relief you must considering to secist, yourselves, and to lay heart the florer ment a

proceedings of the Examiners at Apothe | proposition before the meeting. Mr. Der. carles' Hall, &c. As I had already formed another engagement, I could not have attended the meeting, but independently of that reason, it appears to me to be best that I should not attend it. But I always hear with pleasure that persons who feel themselves aggrieved, assemble to consider and discuss the subject of their grievances, and individually I should, without doubt, have derived much gratification from the information to be received by attending the discussion. With earnest wishes for the prosperity of the medical students of London. I have the honour to be, Sir, &c.,
"HENRY WARBURTON."

(Enthusiastic cheering followed the perusal

Gentlemen, I shall not detain you longer, excepting to entreat that you will universally join in the work we have begun, and I am sure if you do, that we shall soon be able to shout a joyous requiem over the remains of that despotic tribunal of injustice, the Apothecaries' Hall, which has been so execrable in its existence, and will be so de-tostable in its death. (Loud cheers.) I beg to move, gentlemen, "That this meeting is of opinion that the examinations, as at present conducted, at Apothecaries' Hall, are conducive neither to the honour of the profession, nor to the protection of the public, nor are they adequate tests of the abilities of the candidates."

the resolution. Abuses, he feared, had exist- into consideration the means of redress. ed in the Apothecaries' Company ever since it had been entrusted with the power of granting licenses. Young men came up to London, devoted the whole of their time to hending the questions which they put, were they would then exert themselves to obtain turned back. It was notorious, indeed, their just rights, and support the dignity of among medical students, that whatever the the profession. (Hear, hear.) talent and scientific knowledge of the candidate, if he relied upon that for passing, without being initiated into some of the queer questions of the Hall, he would fail. (Hear, hear, hear.) He most cordially supported the resolution.

obtained, said, Gentlemen, I wish to address (Laughler.) I come here as no spy, you for the honour of the pupils at large, ("Oh!") The gentlemen who know me their future welfare, and their future cha-know my least. (Laughler, and a cry of racter in the profession. (Laughter, and "Hear Mr. Darmelf's demonstration of cries of "Hear, hear,")

mott our speak after the next resolution has been moved.

Mr. Evans proposed the second resolution. If they were disposed to hear the gentleman who was so many years older than himself, he (Mr. E.) would super will ingly give way to him. (Ories of "No, no, go on.") He thought that at no time were the students called upon to be more unanimous than at present. Until lately the flagrant acts of injustice commisted by the Apothecaries' Company had been kept in the background; but within the last few months, two most glaring cases had come within his own knowledge, -one was that of a most scientific man who was rejected at the Hall. Strong, however, as were his feelings on the subject, he would not abuse the Apothecaries' Company, neither, he trusted, would others at this meeting, as that would be placing in the hands of the Hall a scourge for their own backs. He was extremely sorry that the Apothe-caries' Company should have put to the test, in the manner they had done, the old proverb-" Didicisse fideliter artes, emollit mores, nec sinit esse feros." (Cheers and laughter.) Certainly the Company was not an instance in proof of the saying. The resolution he had to propose was as fol-

"That with a view to procure a remedy for the evils indicated in the foregoing reso-Mr. Scorrans, with pleasure, seconded lution, it is expedient that this meeting take

Mr. Publicomne seconded the resolution. In case, he said, any among them had been brought there by idle curiosity, London, devoted the whole of their time to or had come in opposition to the objects of perfecting themselves to practise in their the meeting, he wisfied that he possessed profession, went up prepared to the Hall sufficient powers of eloquence to impart to to pass, and often, in consequence of the them the same feeling as he himself pos-Examiners themselves not properly compre- sessed upon this subject, as he was sure

Mr. DERMOTT. Mr. Chairman and gentlemen, I wish to address you before the resolution is put, and even Mr. Wakley, as a conscientious friend. (" Hear, hear, great laughter.) Now, gentlemen, I think that this resolution is alleding as it were ported the resolution.

The CHALRMAR then put the resolution to a point of homour; and I thiak, and to the meeting, when one hard was held up against it, which caused great laughter, and cries of "Let him come forward" having carisen, the dissentient advanced to the platifier, and was announced to the meeting as Mr. DERMOTT, who, when allence was a collusion of the cries of "Go on, so or "out, gontlemen (cries of "Go on, so or "out, gontlemen

The CHAIRMAN, There is at present no. The CHAIRMAN, Lishell take care that

I must request that Mr. Dermott will have the goodness to keep to the object for which, we are assembled,—that point is, the conduct of the Examiners of the Hall.

Mr. DERMOTT. I will do so. The universal interest of the profession is involved, and it might be put to the Company of Apothecaries as a point of honour, inasmuch as their character is concerned in a professional way, that they should examine this man publicly. That is the question I wish to propose to this meeting, and if you wish to put me down on the strength of that question, for God's sake if you can conscientiously put me down, do it. ("No, no, yo on, yo on.") Well, then, I say their honour as professional men, their honesty in some slight degree as professional men is concerned, and therefore, upon the score of the interests of the pupils at large (laugh-ter), I would wish, instead of that former resolution, that this gentleman should be examined publicly before the Apothecaries' Company, and I trust it will be seconded. I put my resolution contra to your second resolution.

No one seconding Mr. Dermott's resolution, it fell to the ground. The second resolution was then carried unanimously.

Mr. PETERS proposed the third resolution. Two or three instances had been adduced relative to the oppression manifested by the Examiners of the Hall, but many grievances were yet unstated. Numerous regulations which were in existence at the time that hundreds of students had entered on their professional studies had since been repealed, or so altered as not to bear any resemblance to their original form. (Cries of " Shame, shame.") It thus became impossible for students to know what to do, they could not tell what would be the amount of their studies, they did not know to what particular branches they should devote their energies, and probably at a time when they might be considered fully competent to practise, some fresh regulations were issued from the Hall, which threw twelve additional months of expense and anxiety on their shoulders. (Shame, shame.) No doubt the Company would say that it was all for the good of the profession, but if the majority of his fellow students thought that such a power ought not to be vested in persons who were not able to till what was and what was met good for the profession, and were liable to abuse their privileges, this was the time for them 50 may so. (Cherre.) A most glaring patence of this abuse happened last sum-Ci- then regulations came out by which Mer. The state of the s

Mr. Dermott is not offended here; but, swayed the Examiners at the Hall in their acts of injustice; and if twenty-five pupils at such a distance had possessed this influence, what could not the multitude do who were then present? (Cherr.)] The resolution he had to propose was, "That in order to attain the object desired, a petition be immediately drawn up and forwarded to Parliament, praying that an equitable and just tribunal be immediately established, and that the Chairman of the meeting do sign such petition on behalf of the students present."

Mr. LANE cordially seconded the resolution.

Mr. DRUITT, of King's College, said, that the petition ought to be signed by those who wished to do so, and not by the chairman on behalf of the meeting, for the resolution might not be approved of by all, and it might be inferred that it was not approved of by all the students who were present. Ho moved as an amendment that the petition be signed by those gentlemen present who wished to do so, and not by the chairman on behalf of the meeting.

Mr. CHALLICE seconded the amendment. Mr. CROOK supported the original resolution, as it was in favour of the usual method of signing petitions. Besider, one of the principal reasons was, that the Hall was not over lenient with an individual whom they considered to be opposed to them. (Hear, hear, hear.) If the students present signed the petition, he had not the least doubt that many of them would feel the effects of that proceeding when they went up to the Hall. The signature of the chairman would save many a man from unjust disgrace during the remainder of his life. (Hear, hear.) Why did not the enemy who (Hear, Acar.) Why did not the enemy who moved the amendment declare his sentiments boldly, instead of endeavouring by a side-wind to overturn the object of the meeting? (Cheers.)

Mr. Dautrr again presented himself amid much opposition. They had been desired, he said, to give an impartial hearing to every speaker. As yet they had had no oppor-tunity of showing that impartiality, but he would now afford them the opportunity. (Hear, hear.) He would state boldly his reason for opposing the latter part of the resolution. He did so in order that it might not be imagined either that the general body of the medical students of London were aware of this meeting, or that they were inclined to support any petition that might be founded on the resolutions which had been and might be passed. He would not attempt to retort upon the sneer that had been but it had not been proved. (Cries of "Oh, Some gentleman had proposed the right of man towards the Apothecarles' Company, a gentleman who had moved a resolution. stated that there was to be no abuse, though he considered that plenty of abuse, and gross abuse (general history), had been used. He trusted they would listen to him for a few minutes, and then he would sit down. (A cry of " It's quite time you did so.") They had come there to discuss grievances, and he wanted to know what the question was upon which the gentleman had been rejected. (Repeated hisses and cries of " Off. of.") (The chairman begged that the meeting would hear Mr. Druit.) He thought they had met to hear grievances discussed, but it appeared that they would not permit it. No grievance in his opinion had been proved, and if it had, he did not consider that they were adopting the proper means of obtaining redress. (Groans and hisses from all parts.)

The amendment was then put, when two hands were held up for the amendment, and the resolution was carried amidst loud ac-

clamations.

Mr. CROOK said, he had to propose a resolution which he considered ought to have been the first, because, while it complained of the present mode of the examinations at say much about their sittiffy, and as to their sentiments on the points under discounties, the fourth resolution, he did not consider ing of men who had come forward on the that he was in any way acting for the do-present occasion, he did hope that the appearance of the Company, and he thought that the carries. Company would, if the opposite meeting agreed with him in considering tunity occasion, he did hope that the opposite meeting agreed with him in considering tunity occasion, he did hope that the opposite meeting agreed with him in considering tunity occasion, he did hope that the opposite meeting agreed with him in considering tunity occasion, he did hope that the opposite meeting agreed with him in considering tunity occasion, he did hope that the opposite time that the opposite tunity occasion, he did hope that the opposite time that the opposite tunity occasion, he did hope that the opposite time that the opposite tunity occasion, he did hope that the opposite tunity occasion, he did hope

ek," and laughter.) After what he con-sphered to be much abuse from the chair-tribunal. That would be as had, unless the higher authority were also to be elected by promised to address them, he would conclude by reading the resolution, viz. :-

"That it is the opinion of this meeting that nothing will more essentially contribute to the honour and efficiency of the profession, and the public good, than that the examiners of the institution under consideration should be elected by the members at large, and that no reform can be satisfactory that does not render the governing body accountable to the governed."

Mr. BARLOW seconded the resolution. Mr. -- said that he thought that the proceedings of this meeting were well calculated to raise the character of the profession in the estimation of the public. It had been stated that the grievances complained of that evening had not been substantiated. He did not stand forward to discuss individual cases, but he contended that the principles on which the examination was based were bad. Before one man had the legal power of examining another upon any branch of the profession, he ought to give proofs that he himself had attained proficiency in that branch, and he would boldly assert that the members who at present the Hall, it also suggested a remedy. He composed the Court of Examiners at Applwas not prepared to go to the extent that thecaries' Hall had not given proofs of prosome gentlemen had who had spoken dur- fick ney in any branch of science whatsoever. ing the evening. He thought that if they (Hear, hear, hear,) It was not a court could utter a word in praise of the Hall, they ought to do so. (Cris of "That's imposition of the noblect of profession in public estimite"); and as impartiality was to be one mation. (Cherrs.) Ought the doors by of the principles of the meeting, he was sure which students entered the profession to be they would listen most attentively while he opened or closed by such a body, just as endeavoured to say a word in favour of that they thought fit; and were the intellectual institution. Since the passing of the Apo- medical students of this kingdom to be thecaries Act in 1815, he presumed that no placed at the tender mercy of a self-elected one would question that the profession and irresponsible tribunal? (Reiterated had been much improved. (Hear, hear.) cheers.) Even if any individual could come if that proposition was conceded he would forward and praise the illustrious Company, say, don't do away with the Apothecaries' -admitting such an absurdity for an in-Company; modify it, reform it, but don't stant-yet it could not be proved that the destroy it. In his opinion the great fault system of examinations was not deserving of the Company was, that the licentiates of of the strictest reprehension, as that of a self-the Hall had not the governing body under elected body. (Cheers, It would never do justheir control. If they had, the Company tice to the public; it would always act upon would never dare to inflict the acts of injustics own private feelings to candidates. Mr. tice of which they had been guilty. Why Drult hinted that it could not be told whether would they had been gainly. Why partitioned has tendent as technique would they destroy the Company? (A voice. the meeting approved or not of the resolu"Have you passed?" Mr. Crook. "Yes, I done, but safely, if a man held up his hand have." The voice. "Well, what do you think by way of voting, he knew what he was of their shifty?" He (Mr. Crook) could not doing, and they all knew what were his say much about their ability, and as to their sentiments on the points under discounted. Mr. Cappus was received with cheers, and and agreement of the many control of the many control of the many control of the many control of the meeting, and that the Memory so, has given a hundred course of lactures opinions of this meeting, and that the Memory control of the meeting of the meeting. on anatomy and surgery; and you may be seared that it gladdens his heart not a little to see such a body of students come forward and say - not, "Do not examine us," but Examine us in such a manner, that the world may see whether we merit or not the diploma. But unfortunately, the examinations have been private, and grossly par-tial. Oh, I could tales unfold relative to the examinations that would harrow up your very souls, but I must not do so. You have now put the matter into a train for alteration. (Cries of "Yes, yes," and "Public examinations.") Can any man, or any set of men, complain of you for this? To your own feelings how gratifying the circumstance, that when you have worked night and day to obtain the reward of study, you can advance to an honographe, and an the reward of your exertions! (Hear, hear.) Yet in this great country, such a reward has never yet had an existence, but the sysyou pay so much, as a surgical apprenticefee, and have an hospital or a wealthy connection, you must be a miserable anothecary, and are shut out from all those offices to have opened to you. Hear, hear, hear, system to possess them. Look at the College of Surgeons. See there the bust of that great anatomist, unhappy Brookes. (Cheers and " Question.") Surely you cannot wish to interrupt me, when I speak of the injustice, the had conduct, the baseness of the College, to that first of anatomists. (Hear, hear, hear) If ever man was entitled to hold a seat in the Council of that College it was Brookes, and, had he possessed it, he would have been alive now; but, gentlemen, I tell it you with tears, that that anatomist died from absolute poverty-from absolute starvation (eries of " Shame"); and the best pepil of the present day might do the same, as another result of the existing excellent object.

The regulation was then put to the most-ing and dirried unanimously. Mr. WAREN-ting their loudly called for, and the Chark-han and he understood that Mr. Wakiey would speak after the next resolution was

Mr. Buar proposed, and Mr. Faner sespeeded, the next resolution win in the

to present to the House of Commons, a petition, to be drawn up, expressive of the hers of the Parliamentary Committee of Inquiry into the state of Medical Education and Practice, be also requested to support the same in their places in the Legislatorial Assembly.

Dr. - Browners said he would briefly address the meeting. He had waded through the profession like thomselves, and he supposed they were now considered as worth less as he was. Suppose that some gentle-man, possessing all the intelligence in their collected bands (laughter), went up to the Hall to be examined, and that very learned Society chose to say, " Sir, how many protoxides of mercury are there?" That would be an ignorant question. The difference between the protoxide, and the doutoxide, and the tritoxide-(The laughter prevented us from hearing the end of the sentence.) honour-conferring examination, to receive There might be individuals in the company not members of the profession, who had come out of curiosity, perhaps, and, there-fore, when he talked about protoxide, and tem of medical education has been loaded deutoxide, and tritoxide, he was talking with difficulties without honours. Unless Greek to them. (Cries of "Question," and "We don't want a lecture on Materia Medica.") He was only following up Mr. Carpue's views. A friend of his was rejected, the other day, for not being able to tell how which your exertions and your talents ought many protoxides of mercury there were. The collected medical wisdom of England Gentlemen, I have, fortunately, made my- said his ignorance might lead him to kill the self independent by professional exertions, King's subjects. If the Court of Examiners-if the Court of Apothecaries would allow him (Dr. B) to come before them, be would put every man of them down. (Laughter.)

Mr. WAKLEY was here called for from all parts, and received with many rounds of enthusiastic cheers. He spoke as follows:-In standing before the meeting on this occasion, I yield rather to the advice of others than to the dictates of my own judgment, although it is my duty, circumstanced as I am, and holding the sentiments which I have professed now for some years on the subject of Medical Reform, to contribute in every possible way to the advancement of your interests, which I know are identified with the best interests of the public. Gentlemen, I have indeed passed a pleasant evening on this occasion. To see you assembled to promote the great and paramount object for which I have myself been so long contending, is a source of gratification to me which I know not how to describe. There is a French saying " that those who help themselves Heaven will help." Your prospect is then truly flattering; and let me at it. tell you that you have to-night settled one

great question of Medical Reform in agree- the exercise of its original and very medal ing to tell the Legislature that your confidence in your information, your attaindrugglets of Loudon, whose labours are far ments, and your industry, is such that you care not for-nay that you invite-a public examination into your qualifications to practise medicine - that you are prepared to submit to an honest, just, and deliberate scrutiny, but that you refuse any longer to be subjected to the dishonest and unworthy practices which are played upon you by the Worshipful Company of Apothecaries of London. (Hear, hear, hear.) When I have urged, time out of mind, that public examinations for degrees, diplomas, and licenses, should be instituted, what has been the invariable reply of your enemies-those who, however, have at the same time professed themselves to be your ardent friends? "Oh, poor fellows!" they have said; " they cannot stand such an ordeal; their nerves would be agitated in public; they would tremble too much; they would be incapable of showing what little talent they do possess." (Much laughter.) Gentlemen, this was a base calumny. You demand this fearful investigation. (Cheers.) And now what will your enemies say, and what will the Logislature respond in deciding on the conditions. the arrangements, and the principles of a New University? (Hear, hear, hear.) How will the corporators in the balls and colleges dare any longer to assert that the medical students of the metropolis are frightened at public examinations: The gentleman who proposed the fourth resolution has stated, manifest in his countenance, that he was anxious to amend but not to destroy the Apothecaries Company. Gentlemen, I will destructiveness on this occasion, but I can is concerned, the foundation of the Company's power, the adoption of his propo-sition by the Legislature, will, most assuredly destroy that Company for ever, for it upsets the very principle upon which it is founded. (Heer. heer. hear.) The Com-pany would lie upon no bed of roses if pub-lic examinations were made essential to the possession of professional privileges. Only imagine the ordeal which the men in the present board of Examiners would have themselves to undergo, and the extent of ignorance they would expose. (Great cheering.) No, no, gentlemen. They are altogether out of place as examiners of medical students. The charter of James I. simply authorized that Company to superintend the stone and nerves of steel,—that he drug-shops of London; and I say, let the suffering has the effect upon your and Hall again occupy its old station. Let it and feelings of hardening them to surre

more profitable to them-whatever their competency or their respectability-than are those which are exercised by the medical practitioners. The chemists and druggists at present are without control; no authority is exercised over them by any company. They do just what they please behind the counter, and you are the suffer-ers. (Hear, hear, hear.) To propose what is suggested in your fourth Resolution, is not to propose a reform in the Company, but its abolition, for in effecting such a change in the Act of 1815 as would be necessary, the Apothecaries' Company would sink to the earth. But in establishing the new University-an institution which if constructed, as it ought to be, and according to the principles which common sense inculcates, will prove of more advantage to the English nation than any institution that has been established for the last bundred and fifty years -in the new University, I say, the views expressed in the fourth Resolution may be most beneficially adopted. To that Institution they must apply, and when I reflect upon the influence which medical practitioners exercise over the minds of the community, the blessings which they confer on their fellow creatures, and the quantity of buman suffering which they daily relieve, -I cannot believe that any reforming Government will be insensible to the demand which you now make. (Great cheering.) with that kind heartedness which is so As has been properly said to night, this is no question of party or of politics; it is a question of the welfare of the English nation, of health or disease, of life or death. All make no comparison between our organs of minor considerations should merge in the accomplishment of the great object you tell him this, that so far as the Act of 1815 have in view. It is right that men should not practise without a most careful and judicious scrutiny into their qualifications; but when I reflect upon the drudgery which you have to undergo for a long series of years, upon your innumerable toils, your perplexities, your anxieties, and the hopes you cherish, I cannot conceive how any man can be so cold-blooded and so hase as to make the very moment which ought to be a period of triumph and honour, the hour of degradation, misery, and diagrace. (Loud cheers.) Gentlemen, such mostings as these ought frequently to be beld. The public know not your case, they know nothing of management of management of management of the case of not your case, they know nothing of point anxieties, nothing of your meridies. Do they suppose that you possess hearts of Hall again occupy its old station. Let it and feelings of hardening them to surrounding the macros of England. It is unterly incapable of executing the duties of so your project in carrying on the duties of so your projection, is marchy mercoarry, high an office, so dignified, so exalted a station, and, therefore, let it be confined to

saint who are continually endeavouring to to-day. In thanking Mr. Ridout, do not relieve their fellow men from the agontes of understand me to rejoice at what has been disease, without once supposing they can derive pecualary profit for their skill. (Hear, hear hear.) The public then ought highly to appreciate the pains and perils which you hear.) It is monstrous to conceive such a undergo in endeavouring to obtain a know-thing. Gentlemen, the rejection is no disledge of that profession which is thus devoted to the wants of the community. If no triumph. (Hear, Acer.) As he cannot thenevour claims are now made for the aid of Parliament, and then enforced as I know they will be, no effort that may be made by designing men can frustrate the object you have shown that you entertain not the have in view. (Great cheers.) Gentlemen, slightest respect for that body. (Universal on this point let me do my political enemies in the House of Commons the justice termining that it shall no longer continue to say that I never yet saw men listen with to inflict undeserved punishment on medical more attention, or treat with more respect, the parties who advocate your interests in the great principle of public examinations the House of Commons. (Much cheering.) must be conceded. They would be perIf there be a shade of difference in this feetly legal, even on the part of the Apotherespect between the two contending parties carles. Company. There is not a singlein that assembly, I am bound by truth to clause, line, word, or syllable, in the act of say, without designing to give offence to any one, that the brightest side is not with the liberal party. (" Hear, hear," from the King's demanded that they should be carried on in College students.) I know not how it hap- private? Nay, I have no doubt that when pens; I cannot conceive from what cause it proceeds, but, really, during the last ses- that the examinations would be carried on sion, when emoluments were proposed for in public. The subject, however, was rese medical men at coroners' inquests, the op- mooted in the House of Commons; the position came from the liberal, and not from the other side of the House. Now I mention this to you because I am anxious that the little misunderstanding which exists in the minds of many persons should be removed. You know a good many members him again, by an application to the Courtof of the House. Try them yourselves: ask King's Bench, for the ninth section of the them what are their objections to giving to medical men their due. (Hear, hear.) Gentlemen, the resolution which was last proposed refers to Mr. Warburton. Your petition is to be placed in his hands. A more proper proceeding could not be adopted. The labours of Mr. Warburton in your cause are deserving of unbounded praise. (Hear, Aear.) His assiduity is unabating, his honesty is unquestionable, his intelligence is of the highest order, and I am sure that no effort will ever be wanting on his part to give effect to any resolution which you may ass. A disaster occurred at the Houses of Parliament last year, by which, as you know, a number of medical papers were consumed; and Mr. Warburton's report has, confequently, been much delayed. The committee will by and by here appointed; and the whole of the evidence, and the reit himsed thereon, will be laid before the Your resolutions, therefore, come in time (loud cheers); and I thank Mr. Ridner for what he has done on this occam; I am most grateful to kint for his la-

called the degradation of the candidate. Who, however, will contend that a student can be degraded at the Hall? (Hear, hear, grace, and the passing the examination is acquire honour in the one case, he cannot get degradation in the other. Why, you yourselves, by your proceedings to-night, students. In establishing a new University, 1815 which prevents them from holding the examinations in public; and who has ever that act was passed, the legislature presumed act, in fact, was passed with scarcely any discussion. But there is another pount. say that the examination of the gensleman who was rejected was an illegal examination. He can compel the Court to examine act requires that the examinations shall be conducted by a majority of the Court, bac he was examined by one individual, consequently it was not a legal examination. There are twelve Examiners, and these must be seven to make a Court. The majority of seven, according to Cocker, is four. Now I am told that there are four tables in the room. Are the Examiners Hydras? Can they multiply their heads as occasion may require, so that a proper number of heads: may be at each table to give a decision in. favour of or against a student? (Heer. Acar.) I say therefore that Mr. Smith, if he chose, could compel them to institute another examination, but I trust be will dono such thing. I hope he will rely on the challenge he has given them to examine him in public, in the presence of his professional brethren. Were such examination given to him, the paltry, miserable, managering, tricky, questions that are now put to stredents at the Hall, would never be progund They are now submitted, not to ascert sons in our cause. (" Hear, seer, rem; and dexterny or many the few life susher of this will describe the country of the country. It is the Court of institute research by indicate who have been elected by public by indicate who have been elected by public the country of the c the depth of the student's information but

and movements of the animal body, and the treatment of diseases. Having proved his competency to discuss and explain those principles, the student would be examined on the details of anatomy, physiology, chemistry, medical practice, &c., the object of the Examiners being to put those questions which are important as tests of knowledge Depend upon it this punishment would prevent another such attempt from being made. the aching heart of unfairly rejected stu-dents, and no feeling of distress can be tation to wait upon the Chancellor of the greater than the disappointment of a meri-Exchequer, because there is a charter now to create. I have known this happen to abilling in London,—the last farthing their Chamber. One of the King's College knot of relatives could devote to their education, students here called out "No politics," which and to the purchase of tickets and certifices was surjety deprecated by cries from all cates. I have known the week arrive when other parts of the room.) It has not been prospects in life have been for ever blasted. the Kraminers themselves to say upon this occasion? They have nothing. They will not fafer in either you or the candidate on what point they refored to grant him the license to practise. He is in total ignorance upon the subject. The Examiners are too stay his hand with reference to the semicautious to make such things known. The conditions of the charter which, when a Examiner who rejected him does not dare framed, may, though injurious to your is If he did, it is fifty to one but that his own years. act, but when I balance the good against in all directions, and that the great body of the former kick the beam with a vengeance. Herr, Reer, Acer.) Whatever may have been the virtues of that body, and whatever may have been the extent of its infirmities, its days, as has been truly stated to-night, are numbered, and you are about to be emancipated from as odious a thraldom as ever existed over a body of intelligent men. (Long protracted cheering.)

Mr. Liston, being loudly called for, presented himself, amidst great cheering, and said-Gentlemen, I feel highly flattered by the kind reception you have given me this evening. I came here only as a spectator of your proceedings. I am a mere tyro in medical politics, but you will find in me a stanch supporter of medical reform. The present system does not work well, and I hope that in a short time we shall have a much better one in its place. (Great cheering.)

The CHAIRMAN then put the resolution last proposed to the meeting, and it was carried without a dissentient voice.

Mr. Cutien proposed the next resolution. After the cloquent manner in which they had been addressed that evening by the friends of the student, there remained little they had assembled with a view to remedy. However, he would make a few remarks, and a few only, previous to reading the resolution. He conceived that they could not do a better thing than arrange plans for the correct guidance of their future endeayours. Every school should send its deputy to a central association, -one selected from among the rest, who was competent to take upon biniself the duty of representing the interests of his fellow students, until the time arrived when the Government might provide a better scheme of medical government, and candidates for licenses to practise were fairly treated by an examining board. This change, he hoped, would not be long before it was achieved, for while they (the students) had much in their own power, they had able advocates amongst their seof the greatest ornaments of his country. (Cheers.) The provincial students could not yet have been made acquainted with the proceedings of the students in London, but it would be right to take into consideration as a future securing the propriety of inviting After the participate in the association which he was absent to propose they should from mocing to the suggestion that a deputation he was absent to propose they should from should be formed of twelve gentlemen to the supportant of the leading to the suggestion that a deputation should be formed of twelve gentlemen to the supportant of the leading the evening, wat on the Chancellor of the Exchequer, to present the resolutions of the evening, professional than the proposed that there would be an exactly described that might emanate from the land promised to head the deputation (cheers); and it remained for the meeting schools, are party disconting as professional transfer that the support of the suggestion that a deputation should be formed of twelve gentlemen to present the resolutions of the evening, professional transfer to the formation of the evening.

the wil, I am afraid that the last makes the students would unite in effecting the regeneration of the medical profession.

(Cheers.) He begged to propose
"That for the better protection of the
interests, and the mutual support of the rights, of the students in medicine generally, of this empire, a great central association be formed, which all medical students be invited to join."

Mr. Wiblin seconded the resolution.

Mr. DRUITT would not have troubled the meeting again, had it not been for this resolution. (Cries of spoke, spoke.) He had not spoken upon this resolution, which he conceived was founded in error. (Cries of "Ok.") They were directed to choose a tribunal from among themselves, to examine themselves: how could they choose a competent tribunal? Would the public respect their decision more than they would that of the Hall? Certainly not; therefore he con-sidered the resolution altogether irrelevant to the present meeting. (Cries of " You're quite wrong."

Mr. CROOK said, that no doubt the meeting would consider him presumptuous in attempting to make any reply to some observations of Mr. Wakley, yet be begged to do so for a moment. That gentleman had been to be said on the nature of the abuses which kind enough to compliment him upon his general good expression of countenance. That was very kind of him. He would conscientiously return the compliment, for if ever there was a man whose countenance portrayed universal philanthropy, Mr. Wak-

ley was that man,

THE CHAIRMAN! You must be good enough, Sir, to keep to the subject for which we are assembled.

Mr. CROOK. I am going to speak in reply to Mr. Wakley. Mr. Wakley condemned the fourth Resolution. (Cries of " No. no. he supported it." "It was carried." "There was only one dissentient.") Mr. Wakley did not support the Resolution. (Cries of " Yes, yes, he did." and " Chair, chair. Mr. Crook then retired, and the Resolution was put to the meeting, when, after the show of hands had been taken, the gentlemen niors, and one amongst them who was one from King's College on the platform being dissatisfied at the smallness of the minority. it was again put to the vote, when ten hands were counted against it, and the Chairman declared it to be carried, with a few dissentients, amidst loud cheering.

Mr. PAINE called the attention of the

suggested that a gentleman should attend we deem it our duty to give it the most from each school which chose to send a representative. The resolution was then carried.

Mr. Swith proposed, and it was seconded by Mr. Spanow,—" That the resolutions passed this evening, be published in the Morning Chronicle, The Times, The Lancet, and The Medical Gazette."

The Chairman was then deputed, in the name of the meeting, to write to the Chancellor of the Exchequer, to know when he would receive the deputation.

The thanks of the meeting were then unanimously voted to the Chairman for his able and impartial conduct in the Chair.

Mr. MEADE returned thanks for the vote, and congratulated the meeting upon the proceedings, and the unbroken steadiness of conduct which had distinguished them. They had proved that they could dispassionately discuss their wrongs, and were capable of using great moral force in re-They had taught the Apodressing them. thecaries' Hall a lesson that night which it had never expected to receive from the students of London. The words, " a marked man," were in common use, when speaking of some candidates at the Hall. No more men, he believed, would be " marked" at that institution. Again returning them his most sincere thanks for the honour they ad conferred upon him, he hegged to say that the meeting was dissolved.

Several rounds of cheers were then given

for Mr. Warburton, Mr. Wakley, Mr. Liston, and the Chairman, and three grouns for Mr. Ridout, and some other examiners at Apothecaries' Hall, and the immense as-

sembly quietly separated.

We have been informed that nearly eighteen pounds were collected at the door of the great room, from students, in sixpences, towards defraying the expenses of the meeting, the advertisements, &c., when the amount received being so ample, the re-mainder of the assembly entered without the necessity for contribution; and the Secretary acquaints us that a letter was forwarded on the next morning to the Chanceller of the Exchequer, requesting that the Right Hon. Gentleman would appoint a time, as suggested, for receiving the deputation.

LATE ELECTION AT THE BICHMOND HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

Sin,-An anonymous communication perporting to be " a statement of facts," respecting the appointment of a surgeon to the Richmond Surgical Hospital, has appeared in your Journal of the 9th inst.

As this statement (so far as we are conperned) is devoid of the alightest foundation, becoming in spery

direct contradiction under the responsibility of our signatures :-

lat. We received no list of candidates from the Government, nor from any other

2nd. We never presumed individually, or as a body, to approach the Government on the subject of the appointment in question.

3rd. Our communication with the Covernment was limited to our giving an official answer to an official inquiry respecting the fitness of Mesars. M'Donnel and Adams to perform the duties of surgeons to the Richmond Hospital.

We have the honour to be. Sir. Your obedient servants, PHILIP CRAMPTON. ABRAHAM COLLES. RICHARD CARMICHAEL.

Dublin, Jan. 12, 1836.

DR. GRORGE GREGORY has just been appointed Professor of Materia Medica, at King's College, Strand. Dr. GRORGE GREGORY proved on a certain occasion, before the Westminster Medical Society, that he was pre-eminently qualified as a professor, and the circumstance that he has been poked into one of the empty chairs of King's Cotiege, proves that his claims have not been forgotten. Verily this institution is in a hopeful state.

It is more than likely that this worthy gentleman would have obtained the post, had there been a dozen candidates, because he was owed something by his party, had not yet been paid, and could at no other time be paid so cheapty. However, the fact is, that Dr. GREGORY was the only candidate. Dr. WEBSTER had previously been officially informed by Mr. Mayo, on the part of the managers of this liberal institution, that "he was not eligible to become a " candidate, because he was a mamber of the " established church of Scotland;" and we may here take the opportunity of adding that Dr. Ritchis, one of the ablest and most scientific men in this country, was also informed some time since by the professors of King's College, that " if he would change "his religious creed, and become a me

LECTURES

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

ENCEPHALITIS.

GENTLEMEN .- Encephalitis consists in inflammation of that part of the cerebrospinal axis which is contained within the cavity of the cranium. Although within the last few years considerable progress has been made in the study of inflammation of the brain, and within that period the science has made a rapid march, thanks to the labours of MM. LALLEMAND, ROSTAN, BOULL-LAUR, and others, yet we are compelled to confess, that in spite of the knowledge which we have derived from these authors. our ideas on inflammation of the nervous centres are not yet very clear or precise.

The difficulties that beset us in the study of disorders of the nervous system in general, are peculiarly great with respect to the brain, where inflammation of the nervous pulp is not characterized, in the same clear and decided manner, by the production of constant and unequivocal symptoms, as inflammation of other important organs, the lung, for example, or the abdominal viscera. The difficulty of appreciating the symptoms, so as to arrive at a precise knowledge of the seat of the lesion, is also increased by the circumstance that we cannot always separate easily the phenomena depending on actual inflammation of the cerebral substance, from the symptoms which accompany irritation or inflammation of the membranes. Hence a great cause of obscurity,a result which, from the nature of the relation between the nervous pulp and its neurilema, it is often impossible to obviate. Besides, inflammation of the substance of the brain is not a disease so common of occurrence as you might be led to imagine from the accounts of certain authors. Encephalitis, as we understand the word, simple encephalitis, uncomplicated with any other disease, is, in reality, a rare affection. You may spend several months at the hospital without having occasion to witness a case: in short, inflammation of the substance of the brain or spinal marrow cannot be considered as a frequent disease, except by those who, too readily confounding similar appearances, have described every anatomical lesion of the cranial contents

The present Lecture supplies a deficiency which exists in Lecture IV, published in our Number for Dec. 19. In order to secure the n for bearing the Discourage of the gradients to whee care the of the lectures was confided prothe professor a special card of rels of the amphitheatre. But on which the lecture on was delivered, this precaution succeeded in grati-

sors, that to report verbatim was not possible. Anxiety to publish the lecture with unquestionable accuracy, subsequently prewented us from giving place, in their proper form, to the brief notes then taken, but we now place before our renders a correct rement of the lecture. It forms the commence-ment of M. Audral's discourse on encephalitle, and may, we believe, be read with as mexpected influx of much advantage now as in an earlier numher. The affair is simply one of transport see themselves close tion, which no foresight or precaution could mevery comfortable have prevented, but which every care has mey, and so since been taken to render immaterial to the profes- the perfection of the course.

denominate as "myelite," all acute lesions of the medulla spinalis.

Symptome simulating Encephalitie.

To characterize inflammation of the nervous centres' presiding over animal life, we must have a certain assemblage of symptoms, into whose particular history we shall presently enter in a manner calculated, as far as lies in our power, to render the subject complete. We say, an "assemblage of symptoms," for if the practitioner should found his diagnosis on one or two leading symptoms alone, delirium, or convulsions, for example, he may fall into the gravest errors. Thus we should avoid confounding with encephalitis the nervous symptoms which present themselves in the commencement or progress of an enterite folliculeuse (typhus fever), at the breaking out of an cruptive malady, and in the course of several other disorders. The greater number of children who have been cut off by an acute disease, present symptoms of disorder of the nervous centres, delirium, &c.; yet we find no reason for believing these nervous phenomena to be conpected with encephalitis. The substance of the brain is healthy; we discover no trace whatever of inflammation within the cavity of the cranium, and are compelled to regard the accidents alluded to as the effect of sympathetic reaction.

Again, towards the termination of several chronic diseases, when the patient has been worn out by long-continued suffering, the nervous system is more or less disturbed, and we observe various cerebral symptoms, yet we are not qualified in attributing them to inflammation. This is frequently seen in cases of pulmonary consumption, where the patient becomes delirious and agitated a few days before death; yet the brain is rather less injected than in the normal state. The contents of the cranium are found in a condition of anemia rather than of hyperemia or inflammation, a circumstance which is certainly important in a therapeutic point of view. In typhus fever, whatever may be its form, no matter with what degree of intensity it may present itself, the nervous system plays an extensive part in the production of the functional derangements observable during life. There is disorder of the brain as well as disorder of the digestive tube, but we cannot affirm that inflammation necessarily accompanies or gives rise distinction when we come to speaked to the symptoms in either system. We may have a typhoid delirium without encephalitis, as we certainly may have a typhoid diarrhosa without inflammation of the mucous membrane of the intestinal canal.

A comparison of the functional disorders yond all doubt that the functions of the their may he deranged, or even profoundly variable, whether

under the name of "encephalite," or who | modified, without any inflammation of the nervous pulp. Thus, nervous traumatic delirium, the derangement of the intellect known by the name of " delirium tremens, &c., are not symptomatic phenomena of an internal cerebral inflammation; far from it; they exist in most cases with a discoloured state of the nervous substance. Instead of yielding to, they are aggravated by sanguineous depletions, and are in many iustances, as you all know, removed as it were by enchantment, under the influence of opium in elevated doses, a remedy which is fatal in inflammation of the brain.

Encephalitis, or inflammation of the contents of the cranium (meninges excepted), differs in several respects, according as different parts of the brain may be affected; it also varies according to the degree of intensity with which inflammation may exist: hence there are

Various Distinctions of the Disease.

In relation to the first head, we may subdivide it into three species. First : Inflammation of the cerebral hemispheres cond: Inflammation of the central medullary parts, viz., the septum lacidum, fornix, and inferior part of the centrum ovale. Third; Inflammation of the cerebellum. Again, with respect to its intensity, encephalitis may be distinguished, like many other inflammations, into acute and chronic encephalitis. Acute encephalitis may be general; the whole mass of the nervous centres being attacked at the same time; but this extensive disease is excessively rare: it may be partial, confined to a small portion of the nervous substance; this is much more generally the case One hemisphere of the brain may be attacked, while the other remains free from any inflammation, or only a small portion of the hemisphere may be implicated in the diseaso; in a word, encephalitis, like congestion, may occupy any part of the cerebral mass. We explained fully the varicties of degree and sent, when treating of cerebral hyperemia, it is unnecessary therefore to repeat details into which we have already entered.

I have distinguished inflammation of the brain into three divisions, seconding to the scat of the affection, viz., tilliammation of seat of the american vary americans of the hemispheres of the entertum; of the central white parts; and, finally, ledament tion of the cerebellum. This is a necessary toms; however, as the anatomical ters are the same, no matter what being the nervous centres may be the sest of the disease, we shall now procood to thatch a general view of the murhid anatomy of encephalitis.

stance of the cerebellum. The first and most remarkable character is an injection. more or less well marked, of the cerebral pulp. The gray and white substance evidently receives more blood than in the normal state; it is more red than natural, tumeded, and sensibly more firm, than in a healthy brain; these appearances are, as you see, also common to congestion. Can we distinguish, with any degree of certainty, whether this abnormal injection is in fact truly inflammatory, or dependent on a simple hyperemy of the cerebral substance? No: simple congestion cannot always be distinguished from this, the first stage of inflammation; it even passes, by insensible degrees, into the latter, and it is often quite impossible to say where the congestion ends, and the inflammation commences. This is not peculiar to the brain, although it is, perhaps, more difficult to distinguish the two lesions, of which we now speak, in the brain than in any other organ. You will find the same difficulty of separating the two conditions in thoracic affections. How often are we at a loss to decide whether a portion of lung is simply engoue and con-gested, or actually inflamed! The abnormal coloration, which distinguishes the first stage of cerebral inflammation, is very various in degree. Sometimes the injection is bright, and the small vessels are excessively distended, even so far as to allow here and there effusion of blood in small quantities, which mass. In other cases the injection is less striking, and when the nervous substance is sliced off, we merely observe a greater number of bleeding points than usual; in the nervous substance sometimes presents a kind of tumefaction depending on the increased afflux of blood to the part; and this turgescence may be carried to such a degree, as sensibly to angment the volume of the cerebral hemispheres: this is a circumstance well worthy of attention. The nervous pulp, submitted to the effects of an irritating cause. Seconds time fied, with wonderful spublic and the cerebral bemispheres, too large for the inclusive osseous case in which contained, become pressed upon, more on this compression of the hedrosis substance than on its irritation. This is the reason why the brain constantly tests to escape from the cavity of the skull, and form a true abscuss; however, encysted with a second with the cavity of the skull, the first stage), the mollecules of parulent and form a true abscuss; however, encysted abscuss results much more frequently from parity of the premote the chronic than from acute inflammation or the cerebral substance. Sometimes the feature of the cerebral substance.

occupy the convolutions, the deeper parts of diseased hemisphere is evidently more de-the cerebrum, the mesocephale, or the sub-voloped than the one on the opposite side, to which irritation has not attracted an increased quantity of fluid. The convolutions appear pressed closely against one another, packed as it were too tightly in the cranium, and the surface of the brain no longer presents the anfractuosities by which it is so characterized in a normal state. The inflamed hemisphere, tumefied in all points, and increased in volume, tends to occupy more space than it should do, encroaches upon the opposite portion of the brain, and thus produces a variety of accidents all de-

pending on mechanical pressure.

In the early state of inflammation, the cerebral substance has probably already acquired a tendency to become disorganized; however, the only lesions we observe, are the two just mentioned, injection of the nervous pulp, with tumefaction, and a slight increase of the normal consistency; but when the inflammation has lasted for a certain time, we observe characters of a less equivocal nature. The inflamed nervous tissue undergoes a change of consistency. It has lost much of its resistance, is noft. and gives way under the least pressure. This is a general law of pathological anatomy, affecting all organs as well as the brain; hence ramollissement, or softening of the brain, may be an effect of inflammstion, and when it is the consequence of acute inflammatory action, the ramollissement is always accompanied with more or less injection of the cerebral substance. we find disseminated through the inflamed chronic inflammation of the nervous pulp, we also have more or less ramollissement, but instead of congestion, or increased vascularity, we generally find an infiltration of purulent matter which has broken down, and, short, the colour may vary from a deep red as it were, dissolved the cerebral substance. to the most delicate rose. However the in- Acute inflammation of the brain may also jection may vary in different cases, we never terminate by suppuration; indeed, we may find this anatomical character alone; thus say generally, that every inflamed tissue has a tendency to generate pus, and that the brain is not exempt from the general law. Hence the presence of a purulent fluid is one of the best proofs we can have that inflammation has actually existed in the nervous tissue, abstraction being made of certain rare cases where its presence in the brain results from what has been called "abscess by metastasis."

The pus exists at first in the form of infiltration; the cerebral substance is then intermixed with a quantity of purulent secretion, which every day renders more and more friable, soft, and at length almost liquid. In proportion as the disease advances (if the patient happens to survive

sion is confined to a single point of the or merely the soft parts which coversthe brain, and we find only one abscuss; at osseous parietes, and it is by no means rare other times, various portions of the hemi- to see encephalitis developed in consequence apheres contain circumscribed collections of of a simple wound of the hairy scalp. A projectile, by its flammation has ever been observed in the rapid passage through the cerebral sub-brain, although cases have been reported in stance, may determine inflammation, with-the "Memoirs" of the old Academy of out remaining in the brain. At other times Surgery, and M. LALLEMAND has described one in his excellent treatise on "Diseases nervous pulp immediately surrounding it, of the Brain." But the lesions we have now irritated by its presence, takes on an inflammentioned, are not the only ones which may matory action. However, these different present themselves in connection with in-bodies are far from producing in all cases an fammation of the cerebral substance. In a immediate effect. It is not rare to see them great number of cases the membranes beremain for a certain length of time in the
come engaged in the disease, and are in
framed in the same way as the pleure so matory symptoms. Thus, in some cases, a often inflame when the pulmonary tissue is musket-ball has remained several months in attacked by pneumonia. It is this affection the midst of the cerebral substance without of the meninges which produces the various producing any accident whatever. At a morbid effusions of pus, serum, or a san-later period, well-marked symptoms of enguineous fluid, that we frequently find be- cephalitis manifest themselves, death entween the membranes, or in the ventricular sues, and on examining the brain, we find cavities, and which give rise to important the projectile surrounded by an abscess, the modifications in the symptoms of this dis-effect of inflammation. case.

Having thus briefly pointed out the leading anatomical characters of encephalitis, let us turn to a consideration of the

Causes which may produce Encephalitis.

These are often the same as the causes of congestion, for the one may pass rapidly into the other; however, there are certain influences that act more specially in the production of encephalitis. In the first rank, we must place external violences applied to the region of the head, -an order of causes, be it remarked, that plays but an insignificant part in the production of cerebral congestion. Thus blows, falls, &c., in a word, any severe injury of the head, may give rise to the development of inflammation within the cavity of the cranium. It is not necessary that the external violence be applied immediately to the head; in some cases a severe fall, even when the individual has alighted on his feet, is sufficient to produce a commotion of the whole body, to such an extent, that the brain suffers a kind of concussion, which at first seems of little consequence, but sooner or later is followed by true inflammation of the cerebral substance. Wounds of the head may be accompanied or not with a breach of continuity. In the former case, the solution of continuity affects the bones of the cranius, train; thus, for the continuity affects the bones of the cranius, train; thus, for the continuity affects the bones of the cranius, train; thus, for the continuity affects the bones of the cranius, train; thus, for the continuity affects the bones of the cranius, train; thus, for the continuity affects the bones of the cranius, train the continuity affects the bones of the cranius.

Sometimes encephalitis is produced by The existence of gangrene is by no means the action of foreign bodies, either blant or

We may discover the cause of encephalitis in certain chronic affections of the brain itself. Thus in some cases an apoplec. tic cell becomes a cause of inflammation. acting on the same principle as a foreign body, and exciting irritation, or true inflammation, in the surrounding nervous pulp. Various accidental productions have a similar influence, and should be ranged under the same category, - cancerous tumours, for example, scrofulous tubercles, especially in children who are at the same time affected with tubercular disease in the other great cavities; inflammation becomes developed around those tubercles; in many cases, indeed, it is chronic, and gives rise to few well-marked symptoms, but in others the inflammation is positive, acute, and terminates the patient's life, for death here cannot be attributed to the presence of tubescular masses in the centre of the nervous system, for these masses existed perhaps for years, without producing any grants cidents. It is to inflammation that most attribute the fatal result, and, sect ingly, we find a greater or less portion of the

quently deposited in the substance of the terminated in the symptoms of cerebral inpia mater; as they become developed, they flammation. In conjunction with the than natural, and there was also some heaving and a dwelling of the organ against the parietes at each systole of the ventricles. The natural sound of the heart was deadened, and the state of the pulse, as you might expect, was irregular, and it was occasionally intermittent. There was, at the same time, a loud bellows sound distinctly heard at each systole. At first this bellows sound, - which, I confess, was not, perhaps, examined with sufficient accuracy in the first instance, or perhaps it was lost in the sibilous state of the bronchial tubes .at first it was thought to be only single, but very shortly afterwards it was discovered that the bellows sound was double.

For the first six days after her admission into the hospital she was placed upon milk diet, and the effect of diarctics was tried. These diuretics consisted of digitalis, squills, scetate of potate, the decoction of taraxacum, with some spirit of nitric ether occasionally,

menia ceased when she was 40 years of age, | and, at the same time, an occasional purgs tive of compound powder of jalap was given. At the end of a week no decrease of this symptoms had taken place, and as I was quite sure that such an imments body of fluid was not likely to be absorbed, the kids it right to direct the operation of paracen-Accordingly she was tesis to be performed She complains of consider- upon her being taken into the hospital to

cussion at the lower part of both sides, above plan of treatment, diminishing the Upon examining the heart, that organ was quantity of mercury, and merely just susfound to beat over rather a larger space taining its influence, the iodine ointment was directed to be rubbed in over the abdomen, in the proportion of a drachm of iodine to an ounce of lard, night and morning, a drachm of such compound at each friction. This, however, produced much irritation of the skin, and distressed her considerably, it was therefore omitted, and she was directed to rub in instead the ung. potass. hydriod. She went on pretty much in the same way, I should say of improvement, from after the tapping had taken place, to about the end of the first week in August, when the belly again began rapidly to fill, and I wished try small quantities of claterium. I so ingly directed the twelfth of a grain terium to be given, with a draching nit. ether. every six hours, but this proved too active, producing great the abdomen, purging her very violently, as exhausting her powers too much. immediately reduced to the twenty of a grain, and own in

quantity it acted too violently. It was then | 15th of November, somewhat more than than acted more on the bowels than she could bear, and ultimately it was reduced to the fortieth of a grain, still in combination with the nit. other, given every six hours. It then acted mildly on the bowels, but no in-crease of urine followed its use. Some dandelion was next given, in conjunction with the fortieth of a grain of claterium every six a pint of the decoction of taraxacum being directed to be taken daily. However, by the end of August, she was as large as before, although her general health seemed somewhat better than when she was admitted.

On the 3rd of September she had become so large, and suffered so much inconvenience, that it was again determined to perform the operation of paracentesis, and Mr. South, who operated on the previous occasion, operated also now, but only three pints of a somewhat ropy fluid were withdrawn, and there appeared to be at last, after the flow had crassed, some substance pressing against, and entirely closing the orifice of the canula, which was withdrawn, an elastic hollow bougie being passed in instead, but with no better success. A small quantity of blood escaped from the wound.

Now, after this second tapping, freely applied, peritonitis supervened, and was met by the ordinary treatment, - leaches, so long as there was excessive tenderness over the abdomen, and calomel and opium, given until the mouth was again sore. When the inflammatory action had subsided, palliative treatment merely was again had recourse to, and she returned to the use of digitalis, nit, ether, and the taraxacum. Still, however, there was, from time to time, pain in the abdomen, which rendered it necessary, when the mercury was left off, to recur to leeches, - even so late as the 2nd of October, soon after which time she became gradually worse, the dropsical symptoms rather increased, the dyspnæa became more violent, attended with excessive palpitation, the pulse excessively feeble, the extremities cold, and the general debility so great that it was absolutely necessary to resort to stimulants of almost every description, -wine, brandy, ether, porter, amnionia; and as there appeared to be periodical spasmodic attacks of dyapmon, Mr. STONE, or Mr. WHITTIELD, prescribed some ethereal tincture of lobelia affata, which considerably relieved her, and this she continued to take up to the se of her death, in somewhat increased reo that I think at last she took as che 16 or 18 minims of the tineture three or four times in the twenty-four hours. in conjunction with, perhaps, a drachm to sech loss, of the spt. wth. sulph. comp.

mened to the thirtieth of a grain, and even three months from the time of her admission.

Now with respect to the diagnosis. There was no doubt whatever that general dropsy existed, with effusion into the peritoness cavity, and an anasarcous state of the extremities and trunk. Her face was occasionally swollen, the lip somewhat livid, the tunica conjunctiva suffused with bile. The dalness on percussion over the region of the liver, indicated disease of that organ,-its enlargement after the tapping proved this to be the fact. The occasional pain in the abdomen evidenced that chronic peritonitis had existed. The mucous, sibilant, and sonorous sounds in the chest, showed chronic inflammation of the bronchial tubes. The entire absence of clear respiratory murmur at the lower part of the chest, and the dulness on percussion on either side, indicated effusion. The stethoscope made the disease of the beart equally clear; I was quite sure that the left ventricle, and, indeed, I believed that the whole heart was enlarged, for it beat over a greater space than usual, as proved by its prolonged impingement against the parietes of the chest. The parietes of the heart and the left ventricle were shown to be increased, by the deadened sound of the heart. I believed disease of the valves to exist, in consequence of the bellows sound. I remember remarking, before hearing the double bellows sound, to some gentlemen present, that, in consequence of the intermittent pulse. I believed the mitral valve was the seat, more especially, of the valvular disease. Indeed, according to my own experience, whenever there is sufficient disease of the mitral valve to prevent it from thoroughly closing the orifice, you have more or less intermission of the pulse, which I do not find to be necessarily the case where there is merely disease of the aortic valves. When I heard the double bellows sound, it did not at all alter my opinion with regard to the discase being seated in the mitral valve; on the contrary, it seemed rather to be strengthened, for . I conceived that some impediment existed to the flow of blood from the auricle which gave the first sound, and that when the ventricle contracted, a portion of the blood regurgitated into the auricle, and thence probably arose the second sound.

With respect to the prognosis, it was quite clear, from the state of the heart, and the presumed state of the liver,-a state which had existed more or less for three years, and especially for two years and five months, - that recovery was not to be expected. One could only attempt to relieve her to some extent, and for a time we succeeded. But now comes a curious point, which renders this a most interesting case as regards the diagmosis, because such a thing is as likely to in the state of th and perhaps some animadversion. I was and in the living membrane of the sorter quite certain,—the fluctuation was so evi- there appeared to be several depositions of dent, -upon first examining the patient, that | atheromatous matter in small patches. very considerable effusion existed in the immediately upon opening the abdomen; peritoneal cavity,—that there was ascites, a considerable portion of serous field escaped. At the first tapping twenty-five pints of There was fluid also in the peritoneal cavity. fluid were withdrawn, and when she again The liver, the stomach, and the omentum. became nearly as large as before, and was were adherent to the abdominal and costal tapped a second time, only three pints came parietes, and were attached, parity to the away. And why not more? Why, because upper arch of the colon, and parily to come of the fluid must been have contained of the superior convolutions of the final in a cyst. But that would seem to contra-intestines. Now there also adhered slightly dict my diagnosis. Was I wrong? Had to the abdominal parietes, and the under I mistaken ovarian dropsy for dropsy into portion of the arch of the colon, a dense, the peritoneal cavity? I was quite sure smooth, pellucid nembrane, about three that I had not committed this error, though times as thick as ordinary scrous memthere might be an ovarian cyst containing brane, which, passing in front of the small fluid, as well as fluid in the peritoneal intestines, appeared to be attached to the cavity.

were considerably hypertrophied. This exactly corresponded with the state of her pulse. There was none of that violent hamdilatation of the ventricle equal to the hyopaque and whitish, throughout almost the whole extent, excepting a portion at its posterior part of about the size of half-acrown, which was redder than natural, and upon which there were small patches of abrasion or ulceration. The greater portion of the lining membrane of the left ventricle was also opaque, and whitish, more especially near the sortic valves. The tricuspid valve was not changed. The left suricular opening, when viewed from the suricle, resembled a small semilunar chink, rendering the action of the valve imperfect, and this opening was but just large enough to admit the point of the little-finger, which then felt an osseous or calcareous deposit. The other portions of the mitral valve were indurated, and converted into almost carti- junctiva. laginous substances. The aortic valves were thickened and uneven, but still were cape—adherent. I have always told you that I am ble of effectually performing their functions, not ashamed to contact my the lightness.

brim of the pelvis and pubis, extending The post-morten examination I think solved laterally on each side of the line, forming a the difficulty. Long-standing slight adhersac, or pouch, filled with scrum. On a sions existed at the upper portions of each more minute examination, Dr. BARKER lung. The right side of the chest contained found that this false membrane passed over about two pints of fluid, the left, about a the bladder and uterus, between it and the pint, containing no flocculi, and not at all rectum, and was then reflected upwards, tenacious. The lungs crepitated in almost posteriorly, and, passing over the lower every part, but they were very considerably portion of mesontery, joined the upper porcongested, almost throughout, but in the tion of the membrane, where it was attached very centre of the most congested parts to the colon. Much of this was capable of there were small portions of the lung which demonstration, but it could not be con-were perfectly natural. The bronchial pletely traced to the arch of the colon-membrane presented chronic inflamma-The convolutions of the small intestines tion, but no mucus. The whole of the adhered slightly, forming numerous small heart was enlarged; the serous surfaces sacs, filled with fluid. The serous memof the pericardium were perfectly adhe-rent, and both auricles were found con-places, as to resemble cartilage. The liver, siderably dilated. The right ventricle was which was much enlarged when cut into, of its natural size, the cavity of the left was of a brownish-red, muttled with spots, was somewhat diminished, and its walls here and there, of a yellowish brown, and very much indurated, but it did not break down on pressure. The gall-bladder was very small, but contained bile. The spleen was mering stroke which would have attended a somewhat enlarged; its peritoneal cont was quite as much thickened as, or perhaps more pertrophied condition of its walls. The than, that of the liver, and granuled, and, lining membrane of the left auricle was when cut into, the spleen was somewhat when cut into, the spleen was somewhat darker, and much firmer, than natural. The kidneys I did not think presented any evidence of disease, although from first to last the urine was more or less albuminous. The ovaries were somewhat enlarged.

The liver [presenting it] is considerably enlarged, and exhibits that mottled and hypertrophied condition which is frequently observed in intemperate people. This woman had drunk much. Its peritoneal surface is exceedingly thickened; the result of chronic inflammation, and so hard, that the point of my finger will not break three its surface unless I use my nail. You's expect, that with such a liver some would be absorbed into the system thus account for the yellowness of the co

I said that the pericardium was

penly, and now I am about to confess that | thing was felt pressing against the canula. I know of no symptom, general or local, by which you can positively say that total ad- was the result of inflammation, but it is quite hesion of the pericardium has taken place. If you place your little-finger in the opening of the valve from the left auricle, you will feel the bony or calcareous deposition which I mentioned, and, viewing the valve from which, from the thickening of the valve, renders it impossible for the valve to close erfectly. What has been the cause of this? Why it is the result of inflammation of the attack which she had two and a half years ago, as she well recollected having suffered pain in the region of the heart at that time, and ever since has experienced great uneasicartilage, with dyspness. She then had pericarditis, which of course ended in adhesion, and hypertrophy of the left ventricle; at the same time there was, no doubt, as most frequently is the case in acute periand valves, it can be no matter for surprise ! that the patient was the subject of bronchitis, effusion into the chest, and general dropsy. These are only the necessary consequences of such an impeded circulation.

The double bellows sound was, I believe dependent entirely upon the condition of uninterrupted flow of blood from the auricle into the ventricle, - the very narrow openbeing quite sufficient, in my mind, to produce the first bellows sound. Then the valve being unequal to close the sperture entirely, as soon as the ventricle had recrived the blood, and attempted to expel it into the norta, a portion, it is true, would go into the aorts, but a portion would necessarily regargitate into the auricle, whence, I believe, originated the second bellows sound.

With respect then to the reason why the fluid was not freely evacuated from the abdomen on the second tapping, I can only account for it this way. Mr. Sours tells that the two openings were perfectly marallel; exactly at the same height, but that he discovered afterwards that he had moria the first operation made his opening in the lines albs, but a little to the left side of it; in that case the whole, or nearly as much field as is ever drawn off by tapping, prior to the first ope p

Now it would almost seem as though this certain, from the size of the membrane which I have described, and from its density, that that membrane was not the result of inflammation between the two tappings. In the first tapping it is probable that there the ventricle, you will see it is so contracted to the first tapping it is probable that there as scarcely to admit of the point of was a larger quantity of fluid than in the the linger, though it can be passed farther second. If the sac existed in the first instance in that direction than from above. There | (at the first tapping), and it was a perfect is a sort of triangular or semilunar pouch, cut de sac, why did so much more fluid come away on that occasion? Why there must have been a less quantity effused into the abdomen at the second tapping, and perpericardium most probably following the haps some alteration in the position allowed the small intestines to press a portion of the sac against the orifice of the canula, and so prevented more fluid from coming ness and a sense of depression at the xiphoid away; for the moment the knife was plunged into the peritoneal cavity at the post-mortem examination, a large quantity of fluid escaped. I can only suppose that the pouch was not perfect, but had a comcarditis, inflammation of the internal lining munication with the general peritoneal of the heart. With such a state of the heart cavity, and that in the first operation the part in which the opening was made, favoured the discharge of all the fluid. Then some circumstances occurred by which the position of the sac was changed; perhaps the bowel fell down a little, and caused pressure against the canula. As two or three the mitral valve. The cortic valves had not pints were drawn off, a portion of the cyst It think, any connection with it. There would collapse, and might be driven against must have been two impediments to the the orifice, and when the hollow bougie was passed, the same result may have taken ing, and those projecting osseons or calca-, place. It is quite clear that this sac must reous deposits just within; either cause have existed at the first tapping, and that a regular organized membrane of such immense thickness could not have been formed between the two tappings. The circumstance reflects not in the slightest degree upon the operator. The same thing would have hanpened to any body. In point of fact, if it reflected upon any one, it was upon me, for my diagnosis, because I had asserted that she was suffering under ascites, that is, I felt confident that the fluid was contained in the general peritoncal cavity. The result of the first operation showed that I was right, but the second proved the existence of a cyst, as well; therefore, I was both right and wrong,-provided the cyst did really exist prior to the first operation, - did exist, I mean, as a perfect cyst, or a cul de sac,without any communication with the rest of

MORTALITY OF INFANTS IN ENGLAND.

By T. R. Educads, Esq., B.A., of Trisity College, Cambridge.

tion.

of five years out of one hundred born, and 4.6 annually out of one hundred constantly living under the age of five years.

If the number of the dving at annual intervals, under the age of five years, he known (as is the case in England', the law of mormined equally well in two ways, either by been complete, or if they had been defendenced by the number of higher on by the in an equal degree we should have observing the number of births, or by observing the number of the living under the 19.9 (the quotient of the above numbers) dying to the births is also given, and reversely. The English returns supply us with both these relations, which reciprocally confirm one another. I have already stated for each county of England the number of deaths under the age of five years, which occur annually for every 100 constantly living under the age of five years. I have now to exhibit the number which die before they complete their fifth year out of

the number dying under the age of five years during the same time. If the no deficiencies in the registered births and deaths, the number dying under five years out of 100 born would result immediately from dividing the latter by the former number ineglecting a small correction; not exceeding two per cent.. due to the births having been progressively increasing). The result thus obtained will be correct, even if THE very great diminution of the mor- the deficiencies are very considerable, tality of infants in England is one of the vided that the proportional deficiencies in most remarkable phenomena of modern the births and in the deaths are the same.

The existence of this diminution is if the proportional deficiencies are not the established upon principles universally ac-; same, the apparent may be reduced to the knowledged as true by all ancient and true result by means of a small correction, modern authorities on the subject of human respecting the amount of which there is mortality. It is, however, highly desirable room for very little difference of opinion that an extraordinary fact of this nature. There are only two estimates before the should be confirmed by a different, though public of the deficiencies in the registered not a more correct, method of avestiga-births and deaths, each of which points to the" same correction of any quotient ob-Public opinion is at present divided be-tween two tables of mortality, the "North-the registered births. According to Mr. ampton" and the "Carlisle." The public Rickman, the registered deaths are to be appears to have adopted these tables as increased nine per cent., and the registered true, and to have believed them applicable births twenty-three per cent, in order to to the English population in general, after obtain the true numbers. According to their respective authors had ceased to be-lieve so themselves. According to the twenty-seven per cent respectively. The Northampton Table, out of 100 horn, 464 iggs of four per cent, of the tutal registered die before they complete their fifth year; deaths are not specified; the true number and according to the same table, out of of the deaths, under the age of five years, 100 constantly living under the age of five are also to be increased two per cent, on years, 14.2 die annually. According to the account of the births having been pro-Carlisle Table, thirty-two die under five gressively increasing. According to Mr. years out of one hundred born, and 8.2 die Rickman, estimate, then, it may be said annually for every hundred living under the that the deaths specified as occurring under age of five years. In all England and Wales, the age of five years are to be increased during the eighteen years 181.30, there $\{4+9+2=\}$ fifteen per cent. According to died of females only nineteen under the age my estimate, the increase is 4+14+2=) twenty per cent.

In England and Wales, during the eighteen years 1813-30, the registered births of females amounted to 3,129,368, and the deaths specified, as occurring under the age of five years, amounted to 522,503. tality at this portion of age may be deter- If the registry of the births and deaths had tive in an equal degree, we should have age of five years. If the relation of the dying to represent the deaths under five years out to the living be given, the relation of the of one hundred horn. But, according to Mr. Rickman, the births are to be increased twenty-three per cents, and the deaths fifteen per cent; the quotient of the corrected numbers will then be 18.6. According to my cotimate, on thereasing the births twenty; seven, and the specified deaths twenty cent, the quotient will become 18.8, The corrected quotients approach so near \$ other, that they may be regarded as id call and it may be assumed as a fa every hundred born.

In the English population returns are rent results may be assumed as a few which all writers will agree; that the stated the number born in each country diminishing them are per conditionally the significant part of the signi

to state the apparent and not the corrected | cent may be deemed superfluous in a case Sambers for each county. The necessary where the apparent results are already thirty confection will not be exactly the same for per cent lower than any other results with every county; and a diminution of ave per which they can be compared.

80 90	4.9	20.40	21.16	
90 100	2.9	34.50	37.19	

The results which I have stated for Engand and Wales coincide almost exactly with he results of my theoretical table of " Mean Mortality " which I published four years igo, together with a complete and most exensive series of life insurance and annuity ables founded thereon. According to this able, the mortality at every age (excepting he period of infancy) is twenty per cent greater than that indicated by the Carlisle fable. Mr. Rickman and his assistant now dust the facts to be within five per cent if my statement, and they consequently adnit that the mortality in England is fifteen er cent higher than that shown by their reviously adopted but now abandoned Carisle Table.

I have been lately informed that Mr. dilne himself, the promulgator of the Carisle Table, has made a tardy acknowledge nent of errors with which he must have seen acquainted for several years past. He low admits that the mortality under five ears, out of 100 born, in all England, is 24 ustend of 32, as he previously stated. He iss, however, apparently admitted only twohirds of what he knows to be the real error. dr. Milne, on the publication of his table, pave "a proof" of its coincidence at all ges with the mortality of the English population. His admission, therefore, that he had greatly over-estimated the mortality in infancy, is tantamount to the admission that he had greatly under-estimated the mortality at every age above fifteen years. The Carlisle Table may, therefore, be considered as shandoned by its parent.

46, Regent square, London; January 18th, 1836.

ARREST OF VOMITING BY CREOSOTE.

To the Editor of THE LANCET.

Sin,—The following cases of stomachic disease, treated by creesote, are at your service, for insertion in your valuable Journal. I remain, Sir, your obedient humble servant.

GRORGE BODINGTON. Erdington, Warwickshire, Jan, 13, 1836.

Case 1.—Mrs. S., a young married lady, the mother of one child, experienced a most difficult labour about two years since, the operation of "turning" having been resorted to, in consequence of an unusual presentation. She has since suffered from relaxation of the uterine system, irregular menstruation, hysteria, and constant sickness, and, on one or two occasions, from uterine hemorrhage; but the most distressing of her complaints has been an almost daily vomiting of food, some hours after taking it, at intervals of two, four, etc., or eight hours, the food always returning in an undigested mass, whatever length of time may have claused from the period of taking the ireal. Thus the dimen, says at two o'clock p.m., would frequently rethen be rejected in the same state as taken, the only change being that per by mastication. She complain senation of tightness and compilated, the cheat, headache, and a market vision, as to amount shrint to her countenance located blacks.

the pulse was small and feeble, and she "case," so that if the Doctor's views and had a constant feeling of weariness and practice do not exactly correspond with prostration of strength. She had been for those of all the carping critics who may some months under medical treatment with exist from John O'Groat's to the Land's End out benefit. She visited Cheltenham in the course of the last summer, and consulted some of the most eminent medical men there with no better result. Returning diligently in reading the great book of namy care, and baving read in THE LANCET an account of Dr. Elliotson's success in the treatment of similar affections by creosote, I tried that remedy, mixing six drops of it in a little mucilage, with six ounces of water. The patient took but two large spoonfuls of this mixture, when a remarkable change took place in every respect for the better. She remained without sickness a whole day and night, which had not been the case any time for six months previous. Her features looked more natural, the headache and dimness of sight disappeared, the catamenia shortly afterwards occurred in a more natural and copious flow, and she appeared as if cured by magic, so sudden and decided was the effect; but being of an irresolute mind, I could not prevail upon her to continue the medicine, on account of its comfortable change, she began to experivailed upon her to take a pill twice a day. afterwards perfectly well.

o'clock p.m., was rejected the next morn-creased.

CASE OF

FUNGUS MEDULLARIS

IN THE

CAVITY OF THE PELVIS.

By Julius Wolfr, M.D., Dublin.

A. P., 16 years of age, and of a slender habit, had, except during some diseases in nauseons flavour. She had taken but one his childhood, been perfectly healthy, up to dose, and in a few days after enjoying her the period at which the affection about to be described made its appearance. When ence a return of the symptoms; I then pre- 15 years of age, he began to support his poor parents by dealing in various small arcontaining one drop of creosote in two or ticles, which he carried in a basket, the edge three grains of aromatic confection. She of which, as he walked, always pressed or continued this for a few days, and remained struck against the upper part of the femur. One day he perceived on the inner side of Case 2. The next case occurred in the the right thigh, about two and a half inches person of an infaut, about eleven mouths below Poupart's ligament, a swelling of old; the sickness continued daily for a about the size of a basel nut, which inmonth, and resisted all means employed to creased by degrees and impeded the motion subdue it. This, like the last, seemed to of the limb. He applied to a surgeon, who consist in a suspension of the process of ordered him to rub it with mercurial ointdigestion, as the mother informed me that ment, and to apply cataplasms; but under rice given to the child for dinner at two the use of these means the swelling in-

the food the child took. It was rejected, practising. I found the swelling of about frequently many hours afterwards, unal- the size of a duck's egg, very hard, uneven, seriad. The consequence was, great pros-immoveable, and insensible to the touch, tration of strength, with fluccidity of the The patient was in other respects very well, muscles, pallid countenance, &c. One drop except that the swelling caused a feeling of tightness over the femur when walking, and,

. It could not be an inguinal or a femoral Comp. The infant perfectly recovered, and bernia, because the swelling had an irre-mended no more medicine, gular shape, was hard, uneven, and in-moveable, and its site did not correspond gular shape, was hard, uneven, and im-moveable, and its site did not correspond with any of the sportures through which

I had no reason to suspect the existence

of psoas-abscess, because the symptoms second finger of my left hand, under which precede and attend such an affection were not present, and no fluctuation was perceived

I did not apprehend it to be fungous medulla, because the manner of its commencement and its course seemed to contradict

the supposition.

I ordered the patient to rub the tumour with a mixture of mercurial cintment and iodine, and to employ, internally, Plummer's powder - (Hydrary, Chlorat, mit.; Stib. Sulphur, Aurant.) This treatment effected Sulphur, Aurant.) This treatment effected no improvement; but a few weeks after I could move the swelling under the skin from one side to the other.

The patient having requested me to deliver him from the inconvenience under which he was labouring, I proposed an operation, as the surest and quickest means of getting rid of it. I expected that after having first made a longitudinal incision, and then detached the skin and fascia late which covered the swelling, the remaining adhesions of the morbid mass could easily be detached with the fingers or the shaft of the scalpel.

Operation.-I performed the operation in the presence of two surgeons, Dr. Henniger and Mr. Lange. After I had cut through the integuments and fascia lata, a convolution of dark-blue vessels, and a cartilaginous mass, closely intermixed with each other, were forced out of the wound. They were enclosed in a white, thick, tendinous membrane, and felt bard to the touch. I introduced a dissecting hook into the morbid mass, with which I drew it forth, and tried to separate the adhesions with the fingers and knife, by which means it came more fully into view. Further examination with the finger showed that the mass had more extensive attachments than was at first apprehended, that it went both deeper between the musicles, and higher towards Poupart's ligament. I enlarged the incision in the akin, and the morbid mass, which was firmly adherent to the muscles, was, with great care, separated, and the muscles were thus laid perfectly bare.

To my great alarm I found now that the ment, into the abdomen, and could not be drawn forth, nor could I introduce my finger, to separate the adhesions. I had thus gut into a difficulty, which, however. I avoured to conceal from the many persons who were present at the operation, nutil, after more accurately examining the wound with my finger, and reflecting a few moments, I came to the resolution of making an incision through the integuments, above Pospart's ligament, in such a manner as is regarded when we wish to use a substance illac artery. Through this locision, was also two or two and a said. which was about two or two and a half rhage. It returned frequently, there long, I introduced the first and quantities, and was always of

eac of the peritoneum, to the peous mu Here I discovered a suft morbid mass, w covered a part of this muscle, and whi could easily be separated from it he the fingers. After this was done, I found in difficulty in separating that morbid po which adhered to Poupart's ligament, drawing forth the mass which I has before separated with my fingers i abdomen. The part thus separated was of the weight of nine and a half ounces.

Morbid appearances. - On examination of the morbid structure, it was found that the part which had been situated out of the abdomen, and which had felt so hard and uneven, consisted of dark-blue dilated and contorted vessels, mixed up with a cartilaginous mass, and little granules of fat, all of which were enclosed in a thick white fibrous tunic. The part situated in the abdomen was soft, like the substance of the brain, attached together, of a gray-white colour, intermingled with a great number of minute red vessels, and enclosed in a thin white membrane. In short, it had all the characters of meduliary sarcoma.

Whether the disease took its origin internally or externally it might be difficult to decide positively. To me however it seems

most probable, that the fungous mass in the cavity of the pelvis was of a later date than that situated on: he thigh, because the patient had never complained of general

indisposition, and any inconvenience he had suffered was limited to the external swelling alone.

Progress.-The wound above Ponpart's ligament was soon healed up by being simply brought together with emplast. adhæsiv., whilst the larger wound below Poupart's ligament was dressed with simple cintment. The patient was put to hed, and an appropriate diet was ordered. Except a very slight degree of fever, which appeared in the evening of the 3rd day after the operation, the patient went on very well, His appetite and sleep were good, and the bowels regular. The wound looked well, and suppurated but little. A few days after, he was able to be out of bed, and could walk up and down the room. In the afth week he went out of down without however, returning to his downer extraording. The wound gradually because amiller, and that of a good quality. In the seventh or eighth week a

operation, one afternoon, a sudden blee from the wound took place, withou known cause, and to such a con amount that the patient was all the bleeding was thus checke able to discover the source of

application of cold water. After a few weeks the patient got a cacheciic look, became low-spirited, and lost his appetite. He had, during the day, at irregular intervals, horripilations, and, towards evening, a degree of low fever. The wound assumed an unfavourable aspect, and ceased to secrete healthy matter, but poured forth, in place of it, serum in great quantities. Out of the botthe wound a brain-like mass again sho forth. Light nourishing diet was now ordered, together with the decoction of the cinchons bark, with sulphuric acid, whilst, externally, fomentations, with the same decoction, and alum, were given. The patient apparently, rallied. His appetite returned. In the evening the fever gradually left him, the wound had assumed a somewhat better appearance, the morbid substance was se-

The patient continued to be in this favourable state for a few weeks, and the wound appeared becoming iess. But he had, now and then, slight fits of intermittent fever, of the tertian type, which was endemic in the village in which he lived; but this was soon checked by using the sulphate of quinine.

In this state the patient remained for a few months. His strength apparently increased, the wound became smaller, and secreted but little of the fluid mentioned. The cachectic appearance of the patient, however, did not leave him, though he said that he felt very well. The wound, which was now about the size of half-a-crown, became again of a whitely appearance, and anew secreted a very considerable quantity of the above-mentioned fluid, so that the patient was constantly wet with it. He grew thin, got evening-fever, and had a dry cough, lost his appetite, and was obliged once more to be constantly confined to his bed. This excessive secretion lasted for six or seven weeks, until at length, by the steady use of external and internal tonic and astringent remedies, it, to a certain degree, diminished. The patient, however, was visibly wasting away; the dry cough was now very teasing, and the bark no longer agreed with him. I ordered Decoct. Lich. Island., Pulv. Sulph. Aurant., Antim., et Extr. Cicut., rues, ouppe. Aurest, Americ, et Estr. Cruf., which disminished the cough. Soon after, however, colliquative pempiration and diarrhosa made shely appearance, together with experience of master, and gengreen decinity, on the se sacrum, and aphabas in the mouth, as that the patient was unable to swallow

in the thirteenth month after the operacaff death ensued, the patient being in a so body was not permitted.

PHENOMENON OF THE PULSE.

To the Editor of THE LANCES.

Sin,—The following is transmitted for insertion in a corner of your periodical:—

Staff-assistant surgeon Dr. Hopkins, having occasion to be absent from town for twenty-four hours, requested me to take medical charge of the detachments, stationed in St. John's, for him until his return. On doing so, he stated that he had been called in the morning to see one of the sergeant's wives, who appeared to be labouring under an attack of modified epilepsy. He had About four hours after (at two p.m.) I visited the patient, and found her presentcreted in large quantities, and the secretion ing the following amongst other symptoms complete coma; the pupils dilated; pulse full, soft, and between 80 and 90. On inquiry, I learnt that she had complained, on the previous day, of headache, and had, on the same evening, got drunk, being accus-tomed to tippling. I ordered fifteen grains of calomel, immediately to be followed by a solution of sulphate of magnesia (3) to sviij of water, 3ij. Om. 6. post. calomelan), wet cloths to the head, and fomentations, and bottles filled with hot water, to be applied to the soles of the feet, the calves of the legs, &c. While I was standing by her side, with the finger on the pulse, she was seized with a sub-epileptic fit, experiencing twitches of the muscles of the face, of the superior and inferior extremities, &c. The pulse, from being full and soft, became a mere thread, and quicker and harder. I was struck with the phenomenon, as I could not bring to my recollection having ever read of such an occurrence during epilepsy, and on reference to my books, I have not been able to find the circumstance recorded. I have conversed with most of my medical brethren here, some of whom have retired from practice for ten, fifteen, or twenty years, but not one of them has ever met with such an occurrence. It is from this circumstance that I have ventured to request the insertion of some particulars of the case. One of two causes must have occasioned the diminution of the pulse's volume, either a muscular "vis insita," partaking of the influence of the epileptic seizure, or pressure of the muscles of the arm and fore-arm. But if the latter was efficient, would not the ar-tery, where it is superficial, at the wrist, rather have increased in volume than otherwise? For if we fill a flexible tube with a fluid. and apply a compressing force to two-thirds of its extent, the remaining third will increase in volume, as a matter of course, if the tube be dilatable. I have always been dis-inclined to allow the claim of muscularity of the arteries; but this case has, I confess a linde staggered my creed. The woman did esta grapjalite

well, the medicine acted conjously, and down to us kietories of recovery, when the next day she complained of nothing but submerged had kin fixteen hours, the beadache and debility. I am, Sir, your days, and even seven weeks, in the water.

obedient servant,
John Fuklongs, M.D. St. John's, Antigua, Dec. 12, 1835.

RESUSCITATION FROM DROWNING.

To the Editor of THE LANCET.

SIR .- My connection with the Royal Humone Society as one of its medical assistants, and the vicinity of my residence to the re-ceiving house in Hyde Park, have led to my being called upon to treat most of the cases of submersion requiring medical aid which have occurred in the Serpentine for some years past. I was there on Christmasday, at the time of the accident which, unhappily, was attended with the loss of seven lives, and took an active part in the treatment of the sufferers.

A committee of the society met to inquire into the circumstances of this fatal occurrence, and the notices of their report in the newspapers have produced a long leading article in the Medical Gazette of the 9th inst. on "The Humane Society and its exertions." The writer entertains the most proposteronely absurd notions relative to asphyria from submersion and resuscitation, and is, in consequence, quite unable to conceive how seven persons could have been lost, out of fifteen taken out of the water and brought into the receiving house, unless there existed a fault somewhere. He, however, lauds the society, and admits that it exerts itself to the utmost of its means. In reference also to the medical men who gave remerance asso to the medical men who gave their gratuations assistance on that day, he mays, "It must not for a moment be supposed that we mean to impute the alightest dediction of skill to the gentlemen employed."

The fact is undentable that here were fiften bodies all at once, and middle one roof, to be attended to by seven middled men. In this view of the case, sartiage, many will rather be surprised,

I have not, therefore, any charge against the society or its medical assistants to Tabut, for none has been made. My object is to point out in your valuable journal the arroneousness of the opinions before alluded . I do not fear that the veriest tyro in the profession will be misled by them, th coming clothed with editorial authority. But it is more than probable that sporty. Due is some than proposed that they may confirm the errors, and distress the minds, of some of the many non-pro-fessional periods who read the medical habdomiddle. The fairest way is to quote the words of the writer. He says, Some worthy old senters have insolid

But as we believe that the age of miracles did not extend to the seventeenth century, when these facts are related to have a pened, and as we have feason to dilak human beings were not differently organi formerly from what they are at present must respectfully decline giving credent the marvellous stories aforestid. We believe, however, that there have been some rare cases of recovery where individuals have remained above an hour in the water." The writer here evidently means under the water. Again, after observing that where submersion is accompanied by apoplexy, the instances of recovery are ex-tremely rare, he aids,

"Not so where syncope occurs, as when a person faints with terror at the instant of submersion, or immediately before; for in this state, as is known, respiration may remain suspended for a period more or less considerable, and probably the greater anomalous, where recovery has been effected after a sojourn of two hours or upwards in the watery element, have been of this de-

scription."
Here, also, I presume we must read suder, instead of is, the water, for persons have been many hours in the water, without having respiration suspended at all. I shall trouble you with only one more quotation. The writer says,

" In the Paris arrangements for the resuscitation of the apparently drowned, twelve hours are taken as the maximum, beyond which there is no hope. Where it is ascer tained, for instance, that a person has been eleven hours submerged, no means of proba ble succour are left untried, and the result of this practice is highly satisfactory." (!!!)

The result in every such case would, course, be precisely similar to that of ender vonting to reanimate the bodies of tho unfortunate persons whose heads have been struck off by the guillotine, and as it is highly indufactory to our writing Parisi friends, I suppose we shall soon hear their labours in this new work of chari Equally vain and fruities would be t ablest exercions to restrictiate those w had been free losses, or sweather the merged. The madical and states of Royal Humana Society are too well in ed to make such ridiculeis said full tempts; but frequently in cases of substances for shorter periods, where there is periodity of success, they do institute it personere in the use of means, out if it spect for the feelings of relatives as of it by standers.

The experiments of the sidest mode te, and the opinio

the result of experience in showing, that I in about the nilmines state and in resultante there is little chance of resuccitation after a ing the bowel. Ordered one grain of body has been more than fee consecutive minutes under the surface of the water. I design whether the major Humane Society possesses any well-authenticated record of a single case of secorary after the body had been submerged more than five minutes. I A mixt believe that every one of the seven persons

who met their death at the Serpentine on Christmas day, had been more than that time under the water-some of them, I know, and perhaps all, very much more. It is not at all marvellous, then, that they were not restored. I am, Sir, your very obedient servant,

GEORGE WOOLLEY. 8, Brompton-row, Jan. 19, 1836.

*_ The above letter reached us last week, but too late for insertion in our Number for Jan. 23rd.-En. L.

STRANGULATED INGUINAL HERNIA

To the Editor of THE LANCET.

Sin .- At the suggestion of my friend Dr. Lubbock, who witnessed the following case, I am induced to submit the same to you, requesting that you will insert it in your Journal, and I shall be glad to be made acquainted through your pages with such observations as may suggest themselves as to the treatment to be adopted under similar circumstances on a future occasion. I remain, Sir, yours respectfully,

W. G. GOWING.

Norwich, Dec. 31, 1836.

CARR.-Nov. 7, 1835. Mr. Lambert, æt. 30, of a robust constitution, by trade a baker, was, on Saturday morning, whilst lifting a sack of flour, suddenly seized with a severe pain in the lower part of the abdomen, which continued above an hour, when he became sensible of a swelling in the left groin, which gave him considerable pain on pressure, and continued to increase until about ten o'clock, when I was summoned to attend him. found him suffering scute pain about the unbilious, and comiting everything which he drauls in the left groin there was a swelling, very time, of an olding shape, of about he size of a same agg, descending about one third dawn the scrotum. I placed in a supine position, and relaxed the cominal aperture, by rating the mages the mages did, and attempted to raturn the mages did, and attempted to raturn the mages did, and attempted to raturn the mages did, and the mages did not be exclude the application of the taxis. Not succeeding, I capt that portion which missediatily converged a tobacco enema, and took at the tamour, which was alightly converged to the mages of the taxis. The stomach was perfectly empty, and not like taxis, and and very much contracted; the intestines,

Eight o'clock. Vomiting continues to harass him; withe 100; great thirst, and a general reattenness. Lurative injections or-dered, which brought away some hard feces. A mixture composed of salts and senna, with five grains of calomel, every four hours.

Nov. 8. Nine o'clock a.m. No sleep; pulse 110; vomiting through the night; tongue clean; slight pain in the bowels, which was not increased on pressure; no motion. At four o'clock the symptoms remained the same. At ten I visited him again, and finding that his bowels had not been relieved, and that the vomiting continued, I gave him another laxative injection, which brought away more feces, and ordered a pill composed of a third of a grain of opium and two of calomel, every two hour

9. He could not lie still for more than a very few minutes; frequent vomiting; pulse 110; tongue clean; occasional pain, which appeared to arise from spasm, as it came on by paroxyams; nearly all the muscles of the body, particularly those of the legs and arms, were affected with spasm. Dr. Lubbock was requested to visit him, and he prescribed one drop of croton oil, and five grains of calomel every four hours, with the effervescent mixture. We met again in the evening, but with no better prospect. Every kind of nourishment was rejected by the stomach; pulse 120; no relief in the bowels.

10. Passed a restless night, took some coffee, which remained on the stomach above an hour. Strength considerably reduced; pulse more feeble and frequent; countenance shrunk, and the mouth frequently filled with a bilious stercoraceous matter; he died at about half-past four.

Post-norten Examination, Six Hours after Death.—On opening the addouren, the por-tion of strangulated intestine, which con-sisted of a knuckle of Heum, about two inches in length, was of a dark brown colour, and adhered firmly and generally to the sac, which so completely encircled its upper portion, as not only to obstruct the passage of the feces through the large intestines, but also the circulation of the blood. Its parietes were thickened, and in-filtrated with blood, its external surfaces (the peritoneal covering) firmly adhering together. Its extreme points rested just within the internal ring, which permitted the finger to enter freely, as also did the external ring. The abdominal viscers gene-rally, presented a healthy appearance, ex-cept that portion which immediately cover-

as far as the strictured portion, were dis-tended with liquid feces and gas. Might not my patient's life have been preserved, if, thirty hours after the hernia was returned, an incision had been made so as to expose the abdominal ring, the bowel (which would have been seen) been drawn down, and the hernial sac slit open?

COPAIBAL RHEUMATISM.

To the Editor of THE LANCET.

SIR,-I read in the last Number of your able Journal the communication of Mr. Eagle relative to the circumstance of copaiba producing the disease termed "gonorrhoeal rheumatism," and beg to add my testimony as to the correctness of the views he has taken upon the subject.

It has fallen to my lot to attend a great number of venereal affections, but in no one instance have I seen gonorrheal rheumatism produced unless copains had antecedently been exhibited. I have now before me notes of a case which came under my treatment last winter, in which the most distressing symptoms supervened on the use of the above medicine. The synovial membranes of the knee were greatly enlarged and indurated: the dorsum of each foot was swelled, and the pain wasso excruciating, that the patient was unable to put his feet to the ground for a period of six weeks. His medical attendant pursued (very properly) antiphlogistic measures, such as local bleedings, saline purgatives, &c., but at the same time prescribed a copaiba mixture. When I was called in to see the patient, I found him labouring under great nervous excitement. and he was exceedingly emaciated; pulse 30; numerous petechiæ on different parts of the body; much fever present, and, altoether, he was in a very precarious state I immediately ordered a discontinuance of the copaiba mixture, but at the same time directed that he should persist in the use of the fever mixture, and that the local bleeding should be renewed. Having pursued this system for a week, he declared himself to be quite "another man," and was enabled to follow his usual occupation. The discharge ceased upon his using an injection composed of the Plumb. Superac. and the Zinc. Sulph.

I might give you other cases, but refrain from doing so, in order that I may not encrosch too much on your valuable columns.

1 am, Sir, your constant subscriber, W. B. Maddock, Surgeon.

London, Jan. 19th, 1836.

CÆSAREAN OPERATION.

4 6 1

TERMINATING PATALLY FOR THE MOTHER AND SUCCESSFULLY FOR THE CHILD.

THE following interesting case, attended and related by Dr. B. G. Keaneross, in Rust's Magazine, will be found in No. 2, Vol. 45, of that periodical, the last-published number of the journal:-

The subject of the case was a female, forty-two years of age, who was now pregnant for the first time. The author was called on to attend her on the 18th of March, and found that she had been in la-bour since the 15th. The midwife in attendance had made several improper attempts, with the hand introduced into the vagina, to change the position of the child, and, moreover, had exercised very violent pressure on the sides of the abdomen, in order, as she said, to hasten the birth of the child. The whole abdomen was now excessively painful; the external organs very red, and also painful. On introducing the finger, which caused a good deal of pain, into the vagina, and exploring the pelvis, the antero-posterior diameter of the inlet was found not to exceed two inches; the child's head presented at the os uteri, which was open, and the motions of the infant could be distinctly felt. The Cæsarcan operation was proposed, and approved of, in consultation, by Dr. Warenstoff, who had performed it twice, and once successfully, for both mother and child.

The patient was a woman of short stature, and evidently deformed by rickets, from which she had suffered in her youth. During the period of pregnancy she caught cold, and still coughed a good deal. The pelvis was much inclined forwards; the distance of both superior anterior spines of the ileum was eleven inches, and the conjugate diameter twelve inches; the conjugate diameter of the inlet was estimated at two inches.

The patient having consented to the operation, the surgeon's first care was to empty the bladder and intestinal canal. The woman was now placed in a bed prepared for man was now placed in a hed prepared for the purpose; two sasistants held her feet; another, placed at the head, wook charge of the arms; a physician, sided by a midwife, was stationed on the left side, and intrus-ed with the important duty of preparing the intestines from protricting during the operation. It was impossible to propage sponges, which are recommended by which and Hedenus, in the house of this point a-male; their place was, therefore, supplied male; their place was, therefore, supplied by folding up a sheet in an elliptical form, and placing it over the front of the literus,

while proper persons took care that it should be applied equally to all the abdo-

minal parietes. The uterus seemed to lie in the middle of the bypogustrium; the first incision was, therefore, made in the lines alba, and successive layers of the abdominal wall were divided, with caution, down to the peritoneum, into which an spening was finally made; the division of the soft parts terminated at one inch and three quarters above the pubes, and extendod wards for five inches and a half.

The uterus now presented itself to view, and an incision was made, in the direction of the external wound, about one inch in length. This was immediately prolonged upwards and downwards, with the bistoury, to the length of five inches and a quarter. The child lay with its back forwards, and the operator proceeded to seek his feet, but was unable to succeed in reaching them, from the contractions of the uterus; the same cause rendered it impossible to seize the head; it therefore became necessary to enlarge both incisions downwards by half an inch; the child was then extracted, and although the uterus contracted strongly, no bowel protruded through the wound; however, the state of the infant requiring some assistance, and the person intrusted with the care of the abdomen having turned a one side to aid the nurse, a knuckle of intestine escaped, but was immediately reduced. The wound was now sponged with warm water, a roll of charpie dipped in oil was placed between the uterus and abdominal parietes; two stitches were applied, and the end of the roll was brought out from the lower angle of the wound, which was left open for about one inch and a half; strips of sticking plaster were also wound round the abdomen, and the wound was covered with a compress dipped in oil, and the whole was retained by a bandage.

Immediately after the operation the woman felt herself well; the pulse, sixtytwo before the operation, had mounted only to sixty-five; the only bad symptom was a slight attack of vomiting, which came on immediately after the patient was placed in bed. She was ordered to take a teaspoonful of the following mixture every hour :-R Decoct. Semen. Lini 3vj; Extract. Hyon ciam. Dj; Olei Amygd. 3j; Syrup. Althan

388.

In the evening the patient's pulse had risen to B4, hard and full; the face coloured; the whole shidesies painful. The symptoms were immediately relieved by an abstraction

of twelve ounces of blood.

20. Morning. She passed a quiet night, protty strong; the lochia now come away; and a bloody scrous fluid is discharged from the inferior angle of the wound. The urine is not discharged by voluntary efforts; the use of the catheter is necessary. The cough which effect previously to the operation is ranch dischalifed. Macu distribution

As to the child, it was a full-grown male well formed, weighing seven pounds and a half, and twenty inches long. The antero-posterior diameter of the head was four inches and a half; the transverse three inches and a half; and the mento-occipital five inches; the breadth of the shoulders four inches four lines. In the evening the woman was pretty well; however, the pain returned in the right side of the abdomen; pulse 75.

21. Morning. The physician was sent for to return a portion of intestine that protruded through the inferior angle of the wound during a fit of coughing. This was returned, and fresh plaster applied, so as to close nearly the whole wound. A clyster was administered without any effect, and benceforward it was constantly necessary to introduce the catheter. Mid-day .- The pain in the right side of the abdomen has become very violent, and extends down to the ingui-nal region. It is diminished by leeching and cold applications.

Ile Amygd. Recen. Excerticat. 3j; f. te-rendo cum aqua; Valer. q. s.; Emulsio 3vj; Est. Hyosciam. 9j; Aqua Lauv-ceras 3iij; Syrep. Althem 3j: a spoonful

every hour.

B. Opii gr. 3; Saech. Albi gr. x; f. pulv. D. S.: to be taken in one dose. A lavement was given without any effect. In the evening the pulse rose to 90; the cough had di-minished, and the pain in the abdomen was

supportable.
22. Morning. The patient assures us she feels well; the pain has not increased; but

the cough is now more violent.

lk Opii gr. 4; Sacc. Albi gr. x; f. p. The two last clysters given have not yet opened the bowels. Towards evening the patient became excited from the numerous visits she had received during the day, and the pulse rose to 112. In the night she coughed a great deal, and the pain of the abdomen became much worse. The epigastric region was now tympanitic, and an evacuation could not be obtained by clysters.

B. Olei Ricin. 3iss; Vitel. ov. No. ij; Aque Valer., a. s. ut f. terendo emulsio 3vi :

a spoonful every half hour.

B. Opti gr. 4; Elworaech. Funiculi gr. x;
f. p. deut. tal. Dos. vi. S. One powder every two hours. The cough was appeared by a few doses of this powder; aromatic fomentations were applied to the abdomen.

23. A discharge of some wind has taken place, but no stool; the pain is less; pulse 100; the urine red, taken off by the eathe-ter. The wound has a good appearance, and union has already commenced.

24. Vomiting of a foul-smelling matter during the night; pulse 96; the countenance

agitated. R. Olei Ricini 3iss; Gummi Mimos 3; Vilel. ovi unius; - Aq. Menthe Piper, Valer, aa. 3iij; f. l. a. emulsio, cui adde Syrep.

Mana 31: a spoonful every hour.

ment with assafetida.

Evening .- No stool ; pulse weak, 104 ; another clyster brought away some wind, which gave the patient relief; she has slept but little since the operation; the cough is much diminished; the tongue is covered with a thick yellow crust.

25. The dressings were reviewed to day; the wound seemed partially united, but the stitches remained firm. An ill-conditioned pus was discharged from the ununited points, especially when the abdomen was pressed laterally. During the night the patient made several efforts at stool, and passed some hard feces; pulse 110; abdomen still painful. The tendency to tympanitis is now evident; the patient is delirious, especially when awakened from sleep. The lochia copious, purulent, and fetid.—N Rad. Caryoph., Velor. Min., aa. 35s. Infunde Aque Ferrid. 30j. Stent per 4 hora vas. tec.; colatura adde Extr. Hyosey. gr. xv; Æther. Sulphuric. 358; Syrup. Althee 3j : aspoonful every two hours.

26. The nervous symptoms continue; the tongue is brown; great thirst; the patient complains of great pain; one stool of hard

feces; pulse small, 115.

27. Pulse 96, more developed. The urine was passed for the first time without assistance, and is less red. On dressing the from each other, four inches. The child wound, its upper edge was found to be When the abdomen is pressed upon, the face gives sign of pain; appetite much he must have suffered from the macompletely lost; thirst; no stool, though a nonvres of the midwife. clyster is administered twice a day.

28. The pain of the abdomen has become more acute and general. The patient received some alleviation after the application of cold compresses. An almond emulsion, with Tinct. Opii and Aqua Lauro-cerus, was

ordered. Polse 120.

29. The pain in the right side of the abdomen is very acute. The patient is much agitated, and cries out in agony. The face expresses great suffering, and has taken on the hippocratic cast, Pulse 140, small, and weak. Aromatic fomentations to the abdomen do not produce any effect as before.

30. A knuckle of intestine has given way, and the feces issue in great quantity through the inferior angle of the wound. Pulse 100. excessively small; face collapsed; abdomen less painful; hands and feet stone cold. The patient sank on the following day, 31st, with the common symptoms of gangrene of the intestine.

Body Examined on the 1st of April.

The edger of the wound, except inferiorly, were so closely united, that it became necessary to divide them with the bistoury. The abdominal contents, with the exception of the uterus and great intestine, were normal. The uterus was contracted to the size of a man's fist. Its inferior segment

A lave- | filled the inlet of the pelvis so much, as to oppose some resistance to its separation. The wound of the uterus was now only one inch and a quarter long, and the edges were filled with healthy granulations. We could observe no appearance of the intestine having been strangulated in the wong The posterior surface of the uterus was to mefied, and of a deep-red colonr. The whole of the colon, as far as the signald fie. was filled with bardened feces. Several deep-red spots were seen on the transverse and descending colon, but no gangrene. The anterior wall of the ascending colon was gangrenous throughout, and near the cæcum appeared two orifices, through which the feces escaped into the abdominal cavity. These openings corresponded in size with two roundish prominences of from one to two lines elevation, which existed on the posterior surface of the uterus. In this part only was there a deposit of yellowish

The pelvis of this patient was removed, and prepared for the museum of Munster; when measured, it was found that the distance between the antero-superior spines of the ilcum was sleven inches; the conjugate diameter of the inlet two inches one line and a half; the transverse diameter five inches; the distance of the tuberositics of the ischia lives still, and is very healthy, a circumstance remarkable enough, if we reflect how

Rust's Magazine, No. 2, Vol. 45, contains a case, with a drawing, of medullary sarcoma, occupying the inferior surface of both hemispheres in front of the decussation of the second pair. The man was killed by an accident, and the symptoms to which this remarkable tumour gave rise could, therefore, only be collected from the report of his relations. We cannot award to them much value. We also find in the same number a very good delineation, with a detailed account, of Mr. Weiss's screw lithotrite.

CASE OF

PARAPLEGIA.

Salary.

ACCOMPANIED BY NON-SECRETION OF UNINE AND FECES.

DURING MANY TEAMS.

Described in a Memoir read at the Academy of Sciences and Arts of Padua. By G. MONTESANTO, M.D.

ABOUT three years ago the author of the above-mentioned memoir communicated to the Aridemy of Medicine the history of a Italian prisoner who passed several feares his life without having expected sisters

Dominica Valetto, at the age of 18 years, fell from a great height. The accident, which occurred so far back as the year 1816, was followed by weakness of the lower limbs, and certain difficulty of excreting both the urine and feces. In 1818 he was committed to the jail of Padua for some crime, and after the lapse of a year, was attacked with inflammation of the spinal marrow. The patient's life was saved by the assiduous care of M. MENATO, but sensation and motion were completely lost in the lower extremities. The paralysis was soon joined by a new order of phenomena. Every day, five or six hours after each report, Valetto vomited all solid and liquid substances that he had eaten. The excretion of feces and urine was now completely suppressed, and in addition to the vomiting by which the meals were daily rejected, the patient was now accustomed, after an interval of a few weeks. to throw up a quantity of stereoral matter by the mouth.

The patient had already passed eight years in this condition, when in the year 1828 he was submitted to the care of M. MONTE-SANTO. From 1828 to 1831, the vomiting of stercoral matter became more rare than before that period, and even sometimes was absent during a very long space of time. However, the rejection of fluids was more frequent, and this coincided with a plethoric state of the body that rendered it necessary to bleed the patient no less than sixty times. The oppressed respiration, hard accelerated pulse, lever, pain in the chest, and mulaise, caused many apprehensions of hydrothorax; in fact, he just escaped falling a victim to this disease in 1830, after a very severe winter, from which he suffered extremely, the unfortunate patient's cell receiving no artificial warmth, while he was unable to cover himself in consequence of the weakness of his limbs.

Under these circumstances M. Monte-SANTO Wrote to the judicial authorities, demanding, in the name of humanity and for the interests of science, that the removal of the patient to the civil hospital might be permitted; but the prisoner had been condemned to confinement for life, and the tri-

bunal was mexorable.

In 1831 the habits of Valetto underwent some change; he preferred the coarsest and t heavy food. He refused altogether but and wine, but drank brandy in abunnance. He expressed a great deal of sufferhis and disgust whenever any other food than his favourite choice was prepared for him. Thus on the 27th March 1832, a little fried the which its are against his will excited the

er Acces. This man, who had become an gis, pulse quick, and violent inflammatory objects of great curiosity to the Italian physicians, alled at length in paicon, and Management of the Italian physicians, alled at length in paicon, and Management of the state incessant though fruities; efforts, conflowers away on the life and maledy.

Deminics Valetto, at the age of 18 years, of the atomach, and the exhibition of the stomach, and the exhibition of the stomach and the stomach and the exhibition of the stomach and the stomach of the stomach, and the exhibition of a pain in the back under which he suffered for several years, an unexpected vomiting of stercoral matter in great abundance came on, and towards the end of April the patient was restored to his former health.

At this period a violent shock of an earthquake threatened to overthrow the walls of his prison, and the patient was transported to another. During his passage he suffered severely from pain in the stomach and spine at each shock of the carriage. The spinal pain now became aggravated, and was accompanied with internal pulsations: the abdomen unexpectedly swelled, as if distended with air. This last symptom, though temporary, was the more remarkable, because hitherto the patient never complained of any painful sensation below the stomach, or in the region of the great intestine, the kidneys, or bladder, even while he suffered most severely in the

neighbouring parts.
On the 20th Nov. 1833, Valetto was attacked with acute febrile symptoms, preceded by a sensation of coldness, and oppressive pain in the head. The fever was arrested by bleeding: the calm which generally followed this remedy was not now attained. Towards the middle of December his sufferings increased : the stomach refused to bear any food; he was depressed, complained of violent pulsations near the vertebræ in which the pain was usually scated, and in spite of frequent efforts was unable to throw up any matter from the stomach. The disturbance of the circulating and digestive organs was partially calmed by a copious bleeding; but the unfavourable symptoms soon returned: the epigastric region was now contracted, while the hypogastrium was hard and tumefied. After an access of very violent suffering, he threw up some liquid, inodorous, insipid matter, and then some bitter fluid. The region about the xiphoid cartilage now became the seat of a new pain; the hands and arms trembled. Towards the month of March 1834, the lower extremities became oxiematous, and presented much of the appearance seen in phicgmasia alba dolens.

On the 12th May, Professor Fabris, chirar-gien-en-chef to the Civil Hospital, visited the patient: he explored the state of the rectum, and found the gut very much contracted, and lined with an inodorous greenish mucus: the finger could not distinguish any portion of the bladder, and the patient seemed so fatigued from the examination, that it was not judged it to introduce a catheter. The patient's health now declined from day to day: the tumefaction of the ere symptoms, excessive cardial limbs began to decline, and at the sar

time he passed a small quantity of urine through the threitin. The urine discharged was watery, nearly free from odour; sometimes he remained for several hours without passing any; at other times he excreted two pounds in the twenty-four hours. It is important to remark that he never had had either incontinence or retention of urine, and that it was never necessary to introduce the catheter, a circumstance so often required in paraplegic individuals.

At about the month of October he was again removed to another prison, in which he survived only three months. By degrees the impossibility of taking food was established; he vomited at once every liquid and solid substance as soon as swallowed.

On the 13th February 1835, the symptoms of an approaching death were visible, when a quantity of fluid feces, without any premonitory sign, was discharged simultaneously from the mouth and anus. Valetto expired thirty-six hours after this phenomenon, in the thirty-sixth year of his age, and after having suffered nearly seventeen years under this most distressing malady.

Post-mortem Appearances.

The autopsy was made on the following day, in the presence of MM. Brugnolo, Caldani, Morgagni, Fabris, Montesanto, Argenti, and Méneghini. The membranes of the brain appeared to be cedematous, but the hemispheres of the cerebrum were firm and well developed; the cerebellum seemed small when compared with the cerebrum. The vertebral canal was normal: the point in which the violent pain existed during life did not present any alteration: in the cavity was found a large quantity of sero-sangui-neous fluid: the chord itself was normal. In the abdomen the stomach was found much distended, and a great deal larger than in the natural state; from the great bulging extremity to the small cul de sac, it mea sured eight Paduan inches and a half; from the summit of the great end to the middle of the great curvature, seven inches. It contained a small quantity of bilious and fecal fluid: its parietes were healthy; the liver adhered throughout to the diaphragm: the gall-bladder, completely empty of bile, contained about twenty or thirty calculi. The external surface of the small intestines was in many points injected, and of a brownred colour: they were contracted here and there, chiefly near the cæcum; they contained the same kind of fluid as the stomach The excum, ascending colon, and a part of the transverse, were normal: from the iliac flexure to the anus, the intestinal parietes were thickened, resistant, and contracted: the inner surface was the seat of numerous ulcerations: the whole canal contained fecal matter,—in the small intestine, very field,—in the large, hard and dry. The liver and pancreas were healthy.

The bladder, accessingly contracted, was concealed belind the pubes; its paristic were much thickened, and it contained a few drops of thick red urine; the cavity was not capable of bolding more than three ounces of fulfil: kidneys bealthy; western faccid, and a little contracted; the spaticles and organs of generation healthy; the vasicule seminal fluid.—Annali Universale, October, 1835.

DISEASES OF OLD PERSONS.

Clinical Researches into the Diseases of Old Persons. Made at the Hospital of Salpetrière, Paris. By M. Hourman and M. DECHAMBRE. Archives Générales, Nov. 1835.

In a former Number we analyzed the first of these interesting memoirs. We now continue the series from the November No. of the Archives Générales, giving the statements nearly in the language of the authors themselves:—

The anatomical modifications, which the respiratory organs of old females undergo, are accompanied by corresponding changes in their functions. The principal belong to acts which are purely mechanical, and which give rise to what are called the "physical signs" of disease in those organs, and we shall presently see how they correspond exactly with the changes which we have before described as taking place either in the formation of the thorax, or in the structure of the lungs.

CLASE 1.—Old Females with the Thorax well developed, the Flesh abundant, &c.

We have already seen that the respiratory organs differ very slightly in this class from the healthy adult; the same is true of the functional acts; respiration is generally performed with care in these females; deep inspirations are executed without difficulty, though not quite so freely as by an adult; however, the conformation of the thorax already produces some modification in its expansion, which we now proceed to notice, In an adult female, the mean antero-posterior diameter of the chest (taken opposite the middle of the sternum) is from six inches six lines to seven inches; the transverse, at the level of the mamma, from nine inches six lines to ten inches, and near the have of the chest, at the level of the eighth rib, from eight inches four lines to hime, inches.

Now, in the old women of the first class, here under consideration, we have found the antero-posterior diameter seven to meet inches six lines; the superior transvense 2.5, to 9 inches; the inferior transvense, the same

esuit. We do not attach is with importance of undergo any change whatever during of the Shesiute length of each of these dis-inspiration. Hence we may already draw meters, best their institive proportion is a pircumentance widently worthy of attention; vance in age, the powers which dilate the her express mathematically what has been aid in the former paper on the lateral flatening of the thorax in old persons; thus we see the superior transverse diameter becoming as short as the inferior one, and rearly approaching the antero-posterior. As to the augmentation of the diameters furing respiration, they take place nearly equally in all directions; but the augmen-ation is always much less than in the idult, never depressing more than four or ave lines. Finally, the sternum, which is projected forwards during inspiration, unlergoes the rotatory movement described by Haller in a very feeble degree. The chest of these aged females is sonorous, but not to an exaggerated degree. When the lungs advance, so as to cover the heart, the precordial region then becomes abnormally sonorous, and we sometimes cannot discover a dull sound over the whole left side of the chest. We can see at once how this circumstance is calculated to produce a false diagnosis in diseases of the heart or periexpansion of the pulmonary tissue has become hardened by pneumonia. Auscultation discovers a vesicular respiration, as in the adult, but it is less deep, less abundant, more large and clear.

CLASS 2 .- Old Females with a Narrow Chest, and reduced more or less to a state of Senile Extenuation.

In proportion as the organs destined to accomplish the acts of respiration, become as it were worn out, the necessity of performing the function seems to diminish. Frequently the rhythmus of the respiratory movement is excessively irregular and unequal in such females. The thoracic parictes sometimes remain for a long period in a complete state of immobility, and then alternate, with a series of precipitate movements. It is in vain that one would endeayour " to teach them to respire." The attempts which they make to breaths regularly seem only to derange the function in a more marked manner, and instead of inspiring and expiring regularly, we see them perhaps exhausted by violent efforts that lead to no result. In the state of expiration, the antero-posterior diameter is here seven inches to 7.8 lines; the superior transverse is eight to right inches and a condition before the number of transverse is eight to right inches and a condition before the number of the last performed with more energy than in the same and a half. During a deep inspiration then is performed with more energy than in the same and a half. During a deep inspiration then it is not the same and the same and the same and the same of the thorax ovarcomes the must also rethat it efter happens in this class weakened muscular power.
The changes dismesters are an inch.
The changes disclosed by

the conclusion, that in proportion as we ad-vance in age, the powers which dilate the chest, and chiefly those that act on the transverse diameters, diminish considerably in force. Thus, whenever they are. able to draw a deep and regular inspilation, we see the thorax elevated all in a mass, carried abruptly upwards, while the first to the last ribs ascend under the akin which covers them. In this manner we have been able to correct, on the living body, the error of Sabatier, who thought the lower ribs were carried downwards, the middle outwards, and the superior upwards. In this general movement of ascension the sternum is raised eight to twelve lines, but it is pushed forwards in a lesser proportion; fixed inferiorly by the depression of the ribs already. de cribed, and superiorly by the ossification of the first, or even second, costal cartilage, the rotatory motion of Haller can no longer be executed; nay, in some cases, the movement takes place in an inverse sense, and the projection of the sternum becomes greatest near the superior articulation.

The facility with which the chest is encardium, when, for example, this accidental larged, either vertically, or from before backwards, is easily explained by what has been said on the persistence of the costovertebral articulations in aged persons. In resumé, we may conclude from what precedes, that relatively to the transverse and antero-posterior directions, the play of the chest in the old person is exactly inverse to that observed in the adult; however, there, fortunately, remains a third direction, almost independent of the osseous case; this is the vertical, and hence the diaphragm frequently becomes the principal inspiratory agent; obliged to redouble its efforts, tho folds of its surface press forcibly against the posterior edge of the liver, and, doubt-less, there form the deep marks before mentioned. How do the respiratory muscles act in the aged person? The space by which the ribs are separated being considerably diminished, the intercostal muscles must lose a portion of their force; however, the other muscles, though weakened by the general emaciation, act freely. We must, in this remark, except the scaleni and sternomastoid muscles, whose direction is changed, and whose power is nearly destroyed, by the change of form which takes place in the upper part of the person during old age. Expiration is sudden and rapid; the chest

sero-posterior, and do percussion in this second class of old per-

is the increased resonance of the chest. In lungs of the third type especially, the sound is as clear as in a person affected with pulmonary empyema: this circumstance, which might readily lead us astray, if we were not acquainted with it, is naturally explained by the rarefaction of the pulmonary cells, and the dryness and rigidity of the ribs. But the results of percussion are also modified according to the different regions we examine. Thus in front, the part corresponding to the internal molety of the clavicle, presents only a moderate degree of sonorousness, much less than we find at the anterior-superior region. This fact is precisely the inverse of what was pointed out by Laenucc in the adult, and depends, 1st. On the almost constant presence of gray or black indurations at the summit of the lung. 2nd. From the great curve of the clavicle in old persons. On the other hand, from the atrophy of the mammæ, it is more sonorous in the region of those organs than in the adult. The sternal region is commonly but little sonorous, from the smallness of the lungs, which do not completely cover the bone, and from the arched form of the latter. It also results from the same disposition, that the heart, more uncovered than it should normally be, gives a sound extremely dull, which corresponds very exactly with its volume. Behind, when the scapulum, in consequence of the inclination of the body forwards, has undergone a movement of rotation, the sound is more obscure in the fossæ of the scapulum than in the adult.

Assemblation.—In old persons of the 2nd and 3rd class (see former memoir), in whom we observe the extreme rerefaction of the pulmonary vesicles, the respiratory murmur varies according as the lung approaches one or other type. In lungs where the vesicles are not yet confounded together, but clongated into an elliptical form, the respiratory sound has lost that full, deep, low character which marks the murmur in the adult person. The bruit is more diffuse; the column of air seems less pressed upon, and appears to enter large spaces. The timbre is also more clear, as if the air struck smaller and more vibrating plates of membrane.

and more vibrating plates of membrane. In lungs of the third type, where several cells are confounded together, the respiratory sound is an exaggeration of the one just described; it appears as if it were bronchial throughout the whole chest, only the force and intensity of the bruit are less. Finally, when one lung becomes extensively diseased, as by pneumonia, and the functions of the other are consequently more active, the respiratory murmur acquires more uniformity, and becomes more vesicular. The resonance of the voice is also considerably modified by old age; in many cases it is so great as to resemble a true bronchophony.

sons, are much more remarkable than in the former. The most general and striking sharp and high the resonance is offended it the increased resonance of the chest. In some all less remarks the increased resonance of the chest. In the increased is not a series a perfect engisters. The broaden remarks a perfect of the pulmonary confronts, this circumstance, which might readily lead us astray, if we abundant, which is mixed with the respict tory mirror.

Connection between the Respiration and Pulse in old Persons.—Authors have spoken a good deal on the frequency of the pulse a different ages. Thus, among other observers, Socmmering and Adelon attribute 130 to 140 pulsations to the new-born child; 120 at one year; 110 at two years; 90 at three years; 80 at puberty; 70 in the adult; 60 and less in the old person. In the year 1832, MM. Leuret and Mitivié made some experiments to ascertain how far this supposed retardation of the pulse in old people was conformable to the truth, and they found that the pulse, far from becoming more slow, was, on the contrary, quicker. Their calculations, however, were made on a limited number of individuals, 34 old men, and 41 old women. As to the frequency of respiration in old age, we find nothing certain in authors. It does not appear that any researches have been made to determine with exactness that point. The experiments we made amount to 312; the women were all examined before the act of digestion had commenced, from half past six to half past seven in the morning: of these 312 individuals, 98 belonged to the first class of old persons; 214 to the second; but we were soon obliged to put on one side 57, on account of the irregularity and inequality of their pulse. There remained then 255 females, free from disease, the youngest 60, the oldest 96 years of age.

The addition of their ages gives a total of 18,960; the average being 74.33.

The sum total of the pulsations is 20,984; the average being 82.29.

The sum total of respirations 5558; nverage 21.79. Hence the relation of the respiration to the pulse is as 1 to 3.41.

1st. Of the 255 healthy women, 83 belonged to the first class, and here we find the following results, viz.,

Addition of ages ... 6195—Mean 74.64
Ditto pulsations 6673—Mean 80.42
Ditto respirations 1755—Mean 21.14

Relation of the respiration to the pulse, 1 to 3.81.

2nd. 172 belonged to the second class; and here we find,

Addition of ages ... 12,765—Mary (2)
Ditto pulsations 14,311—Menget Applito respirations 3,803—Mean 21,11

Thus we see that both the pulse said respiration are more quick in the second rlam than in the first. We may first quarter conclusions from the numbers just stablished. In the first plate, the prefixe than-

The same with the same of the

ber of sulfitions in the 355 momen being frequent than in the second class, who, \$2.23, fully confirms the opinion of M. Leunext as to the frequency of the pulse in old are more worn down, more decreptd, more
generally attainaged to the adult, and even
tween the prise and respiration, it always
by 17 the average number found by MM. remained the same, it is a consistency of the constant of the same of the constant of the same of the the Veterinary School at Alfort. On the classes was sirultaneous and proportioned to the Veterinary School at Alfort. On the classes will be adopt 20 as the mean was not be always and by dividing the whole numbering to M. Magendie, we find the respiration into 6 series of from 60 to 140 pulsations, we also accelerated in the old person by 1.79, find that in two-thirds of the old persons Finally, if we reconsider the division made the pulse beat at from 70 to 89, and in oneof old persons into two classes, and compare sixth at 90 to 99. It is also curious to exthe results of each, we obtain another amine the progressive augmentation of the curious result, fully confirming what has pulse and respiration: both these functions just been said; we find that in women of augment in frequency together, but the first the first class, younger by constitution than more rapidly than the second. Let us take by age, the pulse and respiration are less an example from the second class.

SERIES.	SERIES. Number of Individuals.		Mean of Pulse.	Mean Respiration.	Relation between the Pulse and Respiration		
Below 60 pulsations	1	79	56	24	1 to 2.33		
From 60 to 69	21	78.38	64.14	18.58	1 to 3.39		
70 to 79	46	74.37	74.37	21.24	1 to 3.50		
80 to 89	54	73.09	83.74	22.26	1 to 3.76		
90 to 99	29	74.22	94.07	25.24	1 to 3.73		
100 to 120	21	73.43	106.52	23.05	1 to 4.79		

The constant relation between the respira- and those derived from the observations of tion and pulse exhibited in the above table is very remarkable; does the same thing occur in cases where the two faculties are disturbed? To answer this question the author had only to recur to fifty seven cases, which, as we before said, they were com-pelled to separate on account of the irregu-larities they presented; of these fifty-seven, fifteen belonged to the first class and fortytwo to the second :-

The mean age of	the women was	66.50
Mean pulse		75.17
Mean respiration		27.75.

Hence the relation of the respiration to the pulse is at 1 to 3.71; but as, in the two classes united; the numbers were as 1 to 3.41, we have a difference of 0.31 furnished. by the fifty-geven cases.

The experiments from which the shows deulations were drawn have been perwild every source of error; the observations moreover, were made on females all placed exactly in the same conditions of salth, situation, nourishment, &c. &c.

.. It tamilles to say a few words on the difpumbers new given, ble eyes!

ENDER .

MM. Leuret and Mitivié at the old hospi-

The thirty-four women examined at Salpetrière gave a mean pulse of 79 instead of 82.19, which results from the experiments of our authors. However, we should remark that the pulse of the natients examined by M. Lebut never passed 100, while that of M. Hourman varied from 80 to 144. Again, of the forty-one old men examined at Bicetre, fourteen coughed; there remain then twenty-seven, who give a mean of seventy-four exactly. The same number our authors found in senarating all the extreme pulsations, and it is curious to observe that M. Lebut declares he did not venture to comprise in his tables a certain number of old persons, although they appeared perfectly healthy, because the pulse presented a frequence which seemed to him incompatible with good health. How easily is the most accurate observer led astray when he allows a preconceived idea to turn him aside from the facts which are before

ANOMALOUS CASE OF LITHOTOMY.

MANABEABLE DELLTATION OF THE CAPSULE OF THE PROSTATE. METY AND

the Editor of THE Landing

Sin,-If you deem the accompanyMix case worthy of admission into your valuable periodical, its insertion will much oblige, Sir, your most obedient servant,

JOHN LIZARS.

38, York Place, Edinburgh; Jan. 22, 1836.

are for the most part our proper instrucdeviations as would certainly occasion the death of a patient in the hands of a timid or flattened plum was instantly extracted. irresolute operator. Of this last class is the following:

hospital on the 29th of December last, and presented the usual symptoms of stone in the urinary bladder, under which he had laboured during the last eight months. He was in this hospital seven months ago under ably, and this is now the tenth day from the the late Professor Turner, who sounded him, but detected no calculus. The day after his admission he was carefully sounded, but no stone was felt; the bladder was rough and fasciculated. He was ordered warm-baths, leeches to the region of the pubes, the misture aque polasse, the uva ursi, and a scton over the pubes. All irritation having been subdued by these means, he was again sounded, and a stone distinctly perceived. A dose of castor oil was administered, and on the following day the lateral operation was performed.

Operation .- All the preliminary steps having been taken, and the existence of a calculus again ascertained, a large stoff was inserted, which could not be made to pass the prostatic portion of the canal. A smaller staff was next employed, which apparently entered the bladder, as its handle was loose and moveable. One of my colleagues held it over the pules, whilst I commenced and the direction where there is least resistance,

mbranous p the profit through the left lobe of which was bard, cardinglinds which was hard, certaingenous, the studges with calcareous depositions. The left forefluger, which guided the lithou seemed to enter the urinary black er, and little fluid, considered to be urine flowed ut, when I begged the staff to drawn. I next inserted a pair of but instead of a calculus, such as the sounding had led me to expect, I discovered nothing but calculi, varying in size from that of a millet seed to that of a pea. I now used a searcher, but was not more fortunate. My finger felt a pouch, equal in magnitude to a crinary bladder, which con-A surgeon attached to a large hospital tained numerous small calculi. One of my has peculiar opportunities for improvement, colleagues, at my request, introduced his and he fails in his duty if he either neglect finger, and the sensation communicated so them, or conceal the useful results of his nearly resembled that of a nucous memobservation and experience. Success, though brane, that he suspected I had wounded the it flatters vanity, is at best an equivocal proof rectum, but convinced himself of the conof merit, for it may happen to the rash and trary by examining that viscus with the unskilful. I now inserted a catheter, which passed tors: from these we learn whether nature the entrance of this pouch, and got into the or art is the more to be blamed for any un-bladder, and urine flowed out. The cathetoward event; but whether successful or ter was replaced by a staff, along which the unsuccessful, those cases are invaluable knife was carried through the neck of the which lead to the detection of such morbid bladder, as there was no substance like prostate gland, and a stone of the size of a

The first incisions into the pouch occupied about one minute; the second incision, Case.—James Brown, a healthy-locking and the extraction of the calculus, about man, fifty-nine years of age, entered the another minute. From fifteen to twenty minutes were spent in examining this pouch.

The patient has bad no bad symptom-no case of lithotomy ever went on more favouroperation.

Remarks .- The anomalous pouch, which rendered this case so complex, seems to me to have been nothing more than the external fibrous capsule of the left lobe of the prostate gland gradually dilated until it be-came as large as the bladder itself.

Crosse, in his work on Urinary Calenius, p. 34, says, "Concretions in the prostate gland, commencing in its duots, often at a distance from their wrethest orifice, even at the very bottom of a duck go on increasing until each duct is enlarged into a pouch, rendering an escape of the concession into the urethra impossible; the narroughtliss by which the pouch communicates with the urethra often becomes closed in consequence of inflammation and effusion of lymph; the pouch is a secreting cavity, which furn additional deposit; and as the depositions. enlarge or multiply, the pouch enlarge

I possess a preparation in my museum with cysts exterior to the urinary bladder, one of which may hold from four to five ounces. These communicate with the bladder. I have also another preparation, where the right lobe of the prostate gland forms

one capsule.

I freely confess that I was not prepared for the complication just described, nor am I ashamed to confess it, since no mention is made of such an anomaly in the writings of the most eminent surgeons, if we except Crosse and Wilson, from whose works I have quoted above, but which I had not

POOR-LAW MEDICAL CONTRACTS.

STATEMENT OF PROCEEDINGS AT THE WHEATENHURST UNION, GLOUCESTERSHIRE.

To the Editor of THE LANCET.

Sir,-I consider it a duty which I owe to myself and my professional brethren, to forward to you what information I possess on the subject of the Poor law Union contracts. An Union called the "Wheatenhurst Union," in the county of Gloucester, is just formed in my neighbourhood, and I am the only surgeon residing within the Union which comprises 14 parishes, containing a population of nearly 8000 inhabitants. I have attended nine out of the fourteen parishes for nearly eighteen years, and have great pleasure in stating that I am much respected by every class of persons, and what is more, I have professionally attended the poor in a manner which has given them said, Mr. Weale got up, and stated that the antics satisfaction; I believe there is not a salary was much higher than he could passer in either of the parishes who would manction, and if we were appointed, the backbarry me in any was he would. of course is self-praise, but I state it simply pointment; that it would be much better to make you fully acquainted with my case, when the Union was first formed, I attraction, I invision, as a parishioner, was know. The addition of the deputy Commissioner at 1001, including everything except mid-(Mr. Wesle), and that the salary should be fired introduced to the deputy Commissioner at 1001, including everything except mid-

Wilson, and as I could wet possibly fulfit Wilson, and the Urinary Organa, at page the duties of the whole Union, I would di-353, also appeared. —I have met with a vide it with a gentleman, Mr. Hoftwow, and

faving contracted, of the store to his employers and the poor. On the evening before the day for electing the officers, I wrote to a friend and patient, a magistrate, to request he would propose me as surgeon to the Union, in conjunction with Mr. Holbrow; in answer to my note, he politely stated that he did not think I could divide the Union as I proposed, but that it would be divided into two districts on the morrow; that probably advertisements for tenders would be made in the papers, and that I had better wait and ree what was done, adding, that he would take care and mention my name. In answer I begged to assure him that if such was the case, and the lowest tender was to be taken, both myself and Mr. Holbrow would decline offering ourscives.

In consequence of this, when the business came on, my friend asked if it was necessary that tenders should be advertised for, and if so, if the lowest would be accepted. The deputy immediately said that it was their usual plan; that he knew medical men objected to it, but that they always "came to." Accordingly the usual form of advertisement appeared in the county papers, and I was informed that the Union would not be divided in any other way than was announced, which was most inconvenient to us as surgeons. We therefore entered into articles of partnership, to obviate this difficulty, and then no objection could be made to the signatures to the returns.

I again wrote to my friend requesting that he would propose us as surgeons to the whole Union at a salary of 150 guineas per year, and it. for each mid-wifery case. There were two other tenders, the one 1401. for the whole, and 11. for each midwifery case, the other 40% for district No. 1, and half-a-guinea for each midwifery case. The gentlemen who made these offers, lived at so great a distance, that very little attention was paid to them, and I am given to understand that seventeen out of twenty of the Guardians were favourable to our election. Before, however, anything could be said, Mr. Weale got up, and stated that the salary was much higher than he could erve me in any way he could. This Commissioners would not confirm our apcase. The Union is fourteen miles broad, and contains 2500 paupers to be attended by the surgeon. Advertisements were again published in the country papers, and in The Lancer (vide Number for Oct. 17), when Mr. Wands and that he should have Tuc "dienday following w s again appointed to. surgeon, when only one tender arrives, town, offering to undertake the duties of the appointment, without making one inquiry as to the extent of country, or the numbers of the poor. This person's name is Mr. Francis Kavier Mosely, a gentleman who has practised somewhere in America. The whole ground-work of their choice was simply his public testimonian, no one knowing whence he cometh, or whither he goeth; and as this adventurer could not immediately become resident, I was requested to take care of my part of the Union, nine parishes, until Mr. Mosely arrived. This. sir, of course, I did without fee or reward, for upwards of a fortnight. The gentleman has now been here more than a month. He has no instruments. I lent him a catheler only a few days ago. He has no horse, nor any means of conveyance whatever, but his legs, to visit his patients. The sick are very numerous, and I have no hesitation in saying that no man, with two of the best horses in the world, could perform the duties he has engaged to perform; I can assure you, Sir, that I would not accept the whole Union at an equivalent salary, because I feel that I could not do my duty towards the afflicted poor, which hitherto I have ever done.

Now, Sir, 1 have stated the situation in which our poor are left. I am constantly harassied by their applications to me for medical relief, and how I am to act I cannot tell. I should state that the professional men in this neighbourhood are tolerably well educated, and I was myself early in attendance on hospital practice in Bath, and filled the office of house-surgeon to St. Bartholoneu's Happital in the year 1812. I have performed most of the operations in surgery successfully, and, amongst them, several in cases of ancurysm. I merely mention this to show, that my claim rested upon a good foundation. I have resided here nearly twenty vears.

here nearly twenty years.

I hee that you will make use of this letter in any way you think proper, and I shall be happy to give you further information if required. The price per head, I should

have stated above, is 91d. per year.

I am, Sir,

Your obedient servent, TROMAS WATTS.

Frempton upon Severn, near Strond, Clobecestershire, Inn. 1936.

RATES OF ATTENHANCE ON THE

SICK POOL

To the Editor of THE LA WEST

Sir,-Your remarks respective w medical contract system cer of the 12th ult., escaped my pe, and the the earnestness with which you urge the necessity for proposing some plan before the meeting of Parliament, which may tend to supersede the arbitrary, unjust, and cruel measures now adopting by the guardians of Unions, under the sanction of the Poor-Law Commissioners and Assistants, I again trouble you on the subject. The circumstances attending the position of myself and other professional gentlemen in this district, as regards the Union, are fully stated in the petition I forwarded to you on the 18th of September last. In the arrangements that may be made, a specified rate of charge per head, on the gross population of each parish, according to the last census, would be the most desirable mode (if fixed at a fair ratio) of obtaining equivalent remuneration for medical and surgical assistance to the poor. Accordingly, I have made below a calculation of the average expense per head, for the last seven years, for medical attendance on the poor of eleven parishes, attended by me for twenty-five or thirty years past. Some of the parishes are contracted for, and others are attended at so much per case, journeys as well as medicines being charged with a liberal consideration towards the rate-payers, and in no instance has the expense been complained of as greater than was just for the services rendered; and on consulting my medical brethren, it appears that the average as nearly as possible corresponds with theirs.

In The Langer for the 5th of December, in which you have stated that the expense for medical and surgical attendance on the criminals in the Penitentiary amounts to 1/. per head per annum, you have also stated that the labourers in the Unions are provided with similar attendance at the rate of from 2s. to 3s. 6d. per head per assum; but I may I think with correctness assert, that in no instance where a ricens assert, that in no instance where a ricense assert, that in no instance where a ricense assert, that in no instance where a ricense assert, that in no instance where a remuneration unions to one half of either sum; and as the precise sum offered by the granulation of the compound parishes is 15.368 persons, full four-fifths of whom are agricultural good, 300. The product offered for medical and suggest a stendance and mediciness operations, midwifery, and trusses for beingles.

There is consider our committee also which I consider our committee and the I consider our committee and that is the instantant in which guardisms, err, lop of an of assistant-commission-bleided marge proportion of the estate of the instantant comme, which perhaps twenty facely supports his family, after in adjustion marked out by the Board as a

in adivision marked out by the Board as a western division, and the person who for many years has been the attendant of such parishes, happens to reside on the eastern side of the line, those parishes are unceremoniously assigned to another practitioner who happens to contract for the western division, thus depriving the original attendant not only of his parish attendance, but, neces-sarily, of a large portion of his casual private practice, owing to his not visiting such parishes so frequently as when in attendance on the poor; and this is done merely in order that the relieving officer may receive certificates of the health of paupers, from the surgeon of his division, although the fact that no inconvenience can arise from the circumstance of the medical man and the relieving officer residing in different divisions, is proved, by the regularity and facility with which certificates have been forwarded, notwithstanding the various parishes have as yet continued to be attended by the original medical practitioners, owing to medical officers not having yet been appointed, partly by reason of their refusal to comply with the terms offered, and partly from the cristence of private contracts with the different parishes not terminating until Lady-day next. I am, Sir, most respectfully, your obedient humble servant,

EDWARD MANNY. East Rudham, Norfolk, Jan. 20, 1836.

The following is the table above mentioned. The contract in the first seven is for medical attendance, cases of surgery and midwifery being charged for exclusively, but included in the average sum stated per head. East Rainham is six miles distant. Nos. 8. 9, 10, and 11, are attended, per case, at the sums stated per head.

ANNUAL ELECTIONS

AT THE

COLLEGE or SURGEONS -- IRELAND.

Edilor of THE LANCET.

Sra, -The fidelity with which you, from time to time, give publicity to the political affairs of the Royal College of Surgeons in Ircland, encourages me to trespass on your valuable columns with a brief statement of the proceedings of this extraordinary corporation on "Hansel Monday."

That being the day fixed by charter for the election of officers for the ensuing year, the Tory party, of black-balling notoriety, mustered all their forces, in anticipation of strong opposition from the reformers. But what, think you, must have been their astonishment when the hour of contest, one o'clock, had arrived, without a single member of genuine reform principles having ap-peared in the board-room, the supposed arena of party conflict! No, not a Peterstreet, nor a Richmond-man, nor a liberal from any quarter, was to be seen on that eventful occasion! It may be asked whence the cause of this apathy? Have not all members of the corporation an equal interest in its prosperity, and are they not all equally bound to maintain its stability? Nothing can be more fair, nothing more rational, than that such a question should arise in the minds of impartial persons at a distance, who are but little acquainted with the internal workings and perpetual intriguing of the predominant party in this immaculate body; but in the estimation of those who are well informed on the subject of College politics, the Moeral party must stand acquitted of any neglect of duty, on the score of absence, on the present occasion. They have, over and over again, endeavoured to assert their rights and establish liberal measures, with a view to keep pace with the spirit of the age, and thereby maintain the respectability of the profession; but no sooner were the doctrines of liberality and fair play sought to be introduced into the proceedings of the College, than that ever-fertile note of dissention, in this unfortunate country, - that tocsin of discord,—" the No-Popery cry,"—was sent forth by that imp of bigotry and intolerance -JACOB, who, in accordance with the enlightened views of his worthy coadjutor in intrigue, Cusaon, resolved on a plan for black-balling every candidate for member-ship, who might be suspected of entertaining either liberal opinions or just views of passing events. The machinations of those narrow-minded individuals, however illjudged or base they may appear to men of honest views, have, hevertheless, so far

MISSTATEMENTS RESPECTING ARTICLES

712 succeeded in converting the College into a blissful moment, embraced Purps species of prisate or party property, that any Thirty-nine Articles!

"Quid non mortalia per formers to preserve the corporation from total and deserved subversion would prove unavailing. They have tried the experiment

who have been left to fight they (11 - 1ered so much temperate parties) who have been left to fight they (11 - 1ered so much of the parties) who have been left to fight they (11 - 1ered so much of the parties) when they can be to be the parties of the parties o battle of independence. They now rely, with confidence, on the exertions of Mr. Warburton, for the final settlement of a question with which he is so well acquainted.

Well, Sir, "the loaves and fishes" of place and corporate honours were quietly left to the disposal of the monopolists, who, I need scarcely tell you, acted most generously towards themselves. Out of twentytwo officers who were elected, there is not one before whose name a conscientious man would venture to prefix the significant adjective independent; and, with two exceptions, their " honours" cannot, in any station of society lay claim even to a character for excessive respectability. By way of clu-cidation, I beg to apprize you that a Mr. Frank White is the new President, and a more fitting personage could not possibly be placed at the head of such a corporation! He is endowed with the convenient powers of the chameleon, and adapts himself to circumstances, by assuming for the time being the political hue of any party which may be rendered available to his own personal interest. In accordance with this judicious rule of acting, he is, in collegiate affairs, a boisterous supporter of every mouopoly and ing that he excites the admiration, of the huthe liberal Chairman of the Parliamentary Medical Committee that he had been most unjustly excluded from the Surgeoncy of Steven's Hospital, solely on the grounds of However. his being a Roman Catholic. not having much confidence in his own word, on a very recent occasion, he felt it necessary, when putting forward his claims, supplications, and lamentations, to the present Government, as a candidate for the situation of surgeon to the Richmond Hospital, to transmit to his Excellency

" Quid non mortalia p Auri sacra fames!"

Lord Haddington had, gire, no idea that the incessant follower sycophant reporties have become the seeds of bigotry of his Government, Surgeon to be uprooted by "the later well make the seeds of bigotry of his Government, Surgeon the component of the component punishing the seeds of bigotry of his Government, Surgeon the component of the component punishing the component punishing the component of the component punishing the component of the compone

religion, how much is thy sacred mame abused!

And who is the Vice-President for the ensuing year? No less a personage than Mr. WHITE's congenial partner and co-ope-ARTHUR JACOB! Yes, Sir, such is the almost incredible fact. White and Jacob are really the President and Vice-President of the Royal College of Surgeons in Ireland! Arcadia ambo!

"Ab! sure a pair was never seen So justly formed to meet by nature."

I forget the next line, but quis istos separ-abit. JACOB, the vulgar buffoon, whose discursive and disgusting harangues are composed of gleanings from the fishwoman's vocabulary, and the resurrection-man's glossary,—he who is the avoiced advocate of black-balling bigotry and monopoly,—the Conservative champion of every corporate abuse,—he who made such an exhibition before the Parliamentary Medical Committee; and yet, on a late occasion (acting on the supposition, no doubt, that the evidence given by the Irish witnesses would never be published), had the effrontery to state at a boisterous supporter of every monopoly and public meeting of the College of Surgeons, abuse which selfishness can suggest; whilst that he was "the man who told the arch-reat parochial meetings he deems it expedient former, Warburton, to his teeth, the absurdity to play the part of the poor man's advocate, of his attempting to put down or interfere with and in this way attract attention, think- the Irish College of Surgeons," - such is the individual who has been elected Vice-Premane part of the community. As a general sident of this once respectable body, which politician, he says he is a reformer, and, in is now dying a natural but a most ignomiconfirmation of this assertion, he stated to nious death. I remain, Sir, your most obedient servant,

OBSERVATOR SECUNDUS. Dublin, January 15, 1836.

LATE ELECTION AT THE RICHMOND HOSPITAL DUBLIN.

To the Editor of Tun Lament.

Sin,-It is much to be regretted that an Hospital, to transmit to his excellency Sim.—It is much to be regretered that make the truth of his original statement to Mr. I alter distinguished more or less usury is your late distinguished more or less usury is your less that brother, the Town-Major, think of the pages of The Labour: this can more the same of this line of proceeding,—he who was contact the "alter of Hymen." on the faith of the late Dr. Blake's money, from recred towards general improvement, where the errors of Popery; and, at the same utility, and the interest of effects. Buth

engenerous and uncandid minority, facts, in order falsely to enlist from (tacts, in order talsely to enlist bout regard to the evils which will Proceed. viz .: -1. The splitting of the reform party; the Protestant portion of which cannot be expected to co-operate with those, who, under the mask of medical reform, would advance the interests of political-religious fanaticism; and 2ndly. The creation in good earnest of similar feelings in the opposite party, which, I am happy to say, have at present their chief seat only in the jealous and excited fancy of your correspondent. Why introduce into a medical journal at all, the exciting subjects of politics and religion? Most urgent indeed should be the occasion to justify such proceedings. Surely the medical profession at least should be the happy neutral ground, where men of science and philanthropy (though belonging to all sects and parties) might meet on equal terms, free from the rancour of those distracting topics. The medical profession is not, nor should it be, political: the terms religion or politics should never be heard in the pursuit of medical science, or the distribution of its honours; and he is but an ill friend to the profession or to science, who will persist in flinging this apple of discord among the members of the one or the cultivators of the other.

It may be quite true that the majority of medical appointments (such as they are, and God knows they are few and shabby enough) is held by Protestants; but it is to be remembered, that until of late years, there were very few of any other persuasion in the medical profession (and even still they form a vast majority), while the patronage was vested in persons of the same creed, they forming the bulk of the respectable classes and the subscribers, -subscriptions very generally conferring proportional influence. Thus what is selfishly objected to by a few, for reasons easily divined, followed

may gratify, as it would appear to pecially free from politics and religion, and result of, acctarian bigotry, but it is is its boast, that, as a body, it has never a kindred with the better feelings of taken any step in the spirit of either. The ority of the profession. It proceeds fact is, the party who in that budy exercise esquerous and uncandid minority, such a perpicious influence, and have metamorphosed a public institution into a private

published, prefer money to religion or politics either; and they look only to the medical reform sentiments of those they wish to promote: thus their president and several others of the officers are at this moment Roman Catholics, and some of the hottest College partisans belong to the same creed, while the claims of Protestants are a disregarded, because they are reformers. So little does religion or politics prevail among the thick-and-thin "College men," that the Chief among them, Cusack, Jacob. and Harrison, have alternately figured as Conservatives, Liberals, and Radicals, and at this moment the public neither knew, nor perhaps care, in which corps to class theth.

Why then object in such unmeasured terms to the recent government appointments to the Richmond Hospital? Oh, but Mr. Adams is a Tory! He never gave any evidence of any such sentiments. All that the public can know, or indeed is to be known, on the subject, is, that he professes the established religion; and is this to be a bar against all promotion? Truly this is onesided liberality with a vengeance !- I do not wish to be the vindicator of Lord Mulgrave's Government, but I must say that all but prejudiced bigots must see, that in this case, at least, he acted properly, not only for the advantage of science and the Institution in question, but also for the interests of that party which gives such obliquity to the optics of "Observator," 1st. It would becay, but not very gracious, to demonstrate not only that Mr. Adams was by far the fittest person in "Observator's" list, for the vacant office, but that none of the others were actually adapted for the position they had the impudence to claim. And, 2ndly, By the promotion of Mr. Adams, two appointments were vacated; one of which was at once conferred on Mr. Cholera White, an ultra Roman Catholic, -and the other, "surassurably shown the condition of things, without any barty malevelence or exclusive legency to the Jerois-street Informary, which out any barty malevelence or exclusive legency to the Jerois-street Informary, which out any barty malevelence or exclusive Catholic in that Institution. I say nothing of the spreament of first.

Any is the profession at this day conducted a summe that he cannot be objected to, inasmuch hostile feeling your correspondent as his sentiments are as much opposed to the sentiments indeed the exertions of an established religion, and his politics are aid the party to which he belongs shall as extreme as those of any Radical of them cades, it). Individuals of course there all. Further than that, Mr. Carajethael could be who are as bigoted as the most infuriate not have had any "jobbing understanding" by or Radical could desire, but neither the with him, as the appointment was made out while Mr. M'Donnell was in Paris. I may also the country of and, enter into any such sense and de, that the arrangement did not enter the commissioners; they were merely consulted as to the propriety of the

To the Editor of THE LANCET.

Sin,-Dr. Macleod having repeatedly libelled Dr. Cummin, a lecturer at the Aldersgate-Street School of Medicine, by giving circulation to a report that Dr. Cummin was the assistant editor of the Medical Gazette, it was resolved by some of the students of the school to inquire of Dr. Cummin, after his lecture on Wednesday last, whether that statement was true. The design was accordingly carried into execution on that eccasion, the impression being very strong, that neither the slanderer of the students at their late meeting, nor any person so intimately connected with the slanderer. ought to continue any longer secret in the person of Dr. Cummin, if the libel were true. It is but justice to Dr. Cummin to make known in your Journal, that his reply to the questions put to him on Wednesday was, that he neither was the author of the slandering article, nor could have prevented its insertion in the periodical in question, nor was connected in any way, directly or indirectly, with the editing, the manage-ment, or the production of the Medical Gazette. I am, Sir, your obedient servant,

AN ATTENDANT AT THE ALBERSGATE-STREET SCHOOL.

Jan. 27, 1836.

CORRESPONDENTS.

To the Editor.—Sir.—In your report of the proceedings of the Meeting which took place at the Grown and Anchor on Montay evening the 1831 of Laguary, a short speech is assertance to "Dr.— BUCNUBLI." Will you allow me to state; that as I

resent on that occu Was thus, generally the time was not spakes by the time was not spakes by the be, Sir, your chedient acreast, Luigh Blundaille, Branch Blundaille, and Blundai

A Hospital Pupil, Glasgow, must be more dore publishing any statement the subject, we must he names of 4 the the offenders and the aggress. letter must be confidentially authenticate

However widely the medical gentlemen have differed, they must all have denied the truth of the impressions stated in Gamma's letter. The details described therein were not " new," but impossible. We can express no other opinion on the case than that already given; and the treatment can be directed with propriety only after a personal interview with any medical gentleman who may undertake to prescribe for the afflicted patient.

Mr. Matthews.-The wax model was a section of the skull, showing the ganglion oticum, with its branches, and the tympanum, published by Mr. Schloss.

We shall feel much indebted to any of our readers who will take the trouble to inform us, by letter (addressed personally to the Editor), of the names and places of residence of such medical men as they know to occupy the office of Coroner in any part of these kingdoms, whether for towns or counties, and whether living near to, or at a distance from, our correspondents, with the dates (or not) of their appointment.

Does Mr. Broackes desire that his letter should be published? Of course we cannot undertake to call upon the three parties whom Mr. Broackes has named. bare reference to those parties proves the truth and accuracy of our brief critical notice. If the statements in the book be satisfactory, whence the necessity for the collateral aid? We have examined the work again, and are now ashamed of the lenity of our first notice. If we have acted unjustly. it certainly is not to Mr. Broackes, but to the profession and the public. If Mr. B. is not contented, we shall have much more to say on the subject; but we hope the book is shelved.

The letter respecting the Doractshire Medical Association, would be charged as an advertisement at the Stamp Office. passage from it, however, showing the objects of the Institution, will be inserted in the next week's LANCET.

The particulars of the meetings at St. Thomas's Hospital and the London University have been laid before us. At the one, nine students in thirty-four, and at the other seven students in four hundred, have put their hands to documents declaring that the Apothecaries' Company is the pink of British medical institutions. The St. Thomas's students are said to have declared the same thing in writing at King's College, pre-

m in ques- | vious to their sall down the Strand to the Borough.

The facts stated by Investi shall bo. published, but it is impossible to and a plac for them this week.

It would be better to lay the y the plan for the which has been "Student's Association," sent to us, before a meeting of the gentlemen who are interested in its adoption or rejecbf ou spondent may therefore he obtained from the publisher.

The report from the Royal Institution will appear next week.

R. R., Jewin-street.-Time fails us for an epistle. Unless the want is urgent, it would be both economy and good policy to wait.

Mr. Baleman.-1. No farther portion has yet been issued. When it appears, our analysis and comments may be resumed -2. The means of conclusion have not vet been afforded us by the only party who can supply them .- 3. Most probably they will,

Mr. Baxter's case has reached us.

The letters of Mr. H. Prater, Mr. Samuel, Mr. Erett, Dr. Kelso, Dr. Wm. Fergusson, George F. (part), A Pupil of the Borough Hospitals, A Member of the Royal College of Surgeons (part), Anti-Humbuy (part), A. King's College Medical Student, A Licentiale of the Apothecaries' Company, and II., are intended for insertioner

We have received a letter from Mr. Meade, the Chairman of the late meeting at the Crown and Anchor Tavern, stating that several untruths appeared respecting him in Dr. Macleod's journal of last week. The space which would be occupied by Mr. Meade's letter in our columns, would be illbestowed on the fabricator of Messrs. Longman's periodical; and we therefore hope that Mr. M. will be satisfied with the above statement relative to its contents.

The report from St. George's is necessarily postponed for a week.

Observator requests us to state that his reply to the "direct contradiction" given by Messrs. Crampton, Colles, and Carmichael, to his statement relative to the appointment of Mr. Adams to the Richmond Hospital, will be forwarded in time for publication in the next number of THE LANCET.

A Student, G. St .- One of Mr. Liston's excellent clinical lectures will appear in our next number.

A Surgeon-We have other reported b Wallace's admirable clinique before for publication.

The statements of Mr. Sopwish in r Mr. Way, are unavoidably omitted this we A Subscriber should endeavour to ob

the information from Dr. A. himself.

ERRATA.—In Dr. Bigmond's paper, TI, for lomelburge, rest rubraces, rest rebrices.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

BY M. ANDRAL

Physician in Chief to the Hopital de in Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine ut Paris.

LECTURE X.

PECULIAR VARIETIES OF CEREBRAL HEMORRHAGE.

GENTLEMEN, - We have hitherto studied only the ordinary symptoms that accompany hemorrhage of the nervous centres; we have drawn merely a general picture of the most common features of the disease. It is now time to lay before you an account of certain varieties that you will meet with in the course of practice. The nervous symptoms are sometimes complicated with others that do not seem to belong strictly to apoplexy. They are even replaced altogether by phethose symptoms? In what do they consist? arise from accidents occurring in the nervupon disorders in the other systems.

Of more muscles of the trunk or extremities. movement in the cases alluded to? No. The sevidently not a phenomenon of hearth of the brain is in a condition quite opposite, morrhage, whose grand characteristic is the and the convulsions depend, not on an exproduction of paralysis; it depends on an cess of blood, not on inflammatory brita-

inflammation more or less intense of the cerebral matter surrounding the apoplectic cell. In other cases the limb is not contracted, but convulsed. We have seen certain examples where, in a short time after the effusion of blood, the limbs and side of the face were sgitated by spasms, by convulsive movements coming on at intervals and with various degrees of intensity. These symptoms either may appear in the memhers affected with paralysis, or, while one side of the body is deprived of motion, the other is the seat of convulsive actions. Upon what do these phenomena, which occasionally manifest themselves as a con-sequence of cerebral hemorrhage, depend? Not in the effusion of blood certainly, for they are too rare. They occur too seldom to permit their arrangement under the symptoms of effusion. In many cases they are probably connected with irritation or inflammation of the nervous pulp or its membranes.

But are we to conclude on the existence of an inflammatory action in all cases where the spasmodic contractions now alluded to accompany cerebral hemorrhage? Does their manifestation justify the immediate employment of antiphlogistic measures?

Certainly not. Take care how you adopt implicitly such an idea. The most unfornomena of a different nature. What are tunate consequences may be the result. Let us suppose a case in point :-- An individual Where are they found? Certain of them falls down suddenly, deprived of sensation and motion; he has been struck, in other ous centres themselves, the rest depend words, with a violent attack of apoplexy. You bleed him copiously from the arm; the first abstraction of blood seems beneficial; Spannodic Affections of the Limbs.

The first class of symptoms which we have now to examine, is that depending the large now to examine, is that depending the large new to examine, in that depending the large new to examine, in continuance of a state which might have an unfortunate termination. This case is not certainly an exceptional ene. You will first cases of cerebral hemorrhage. Thus, in practice, but can we admit the presence of inflammation to explain the disorders of the runk or extremities. In womener in the cases alludad to? No.

No. 649. *

3 Bearing and

tion, but on a partial anemia of the cerebral homispheres.

There are certain other disorders of movement which accompany hemorrhage of the nervous centres, not as regular symptoms, but as extraordinary and rare phenomena; these algubia must notice in their turn. We have rarely had occasion, indept only three times, to see patients labouring united the symptoms of cerebral hemorrhage, who presented a peculiar phenomenon of a very extraordinary nature; these individuals were at certain moments seized with an irresistible desire to advance, to run directly forwards, and, again, at certain other instants, they experienced the same irresistible inclination to go backwards. Howere we to explain this curious symptom; this strange alternation of two opposite impulses? It is difficult to find a satisfactory reason; however, we may recall to mind, as connected with the subject, the experiments made by M. MAGENDIE to show the influence exercised by lesion of different parts of the brain upon locomotion. You may remember, that when M. MAGENDIE removed the bemispheres of the brain behind the corpora striata, he produced the first strange derangement of motion; and when he destroyed, or took away, the whole of the cerebellum, the animal, instead of advancing, constantly retrograded. Is there anything analogous to be observed in the cases of the patients to whom we have just alluded? Have we found any special alteration in the brain, which would account for the perversion of movement which they exhibited? These are questions which it is impossible to answer in the present state of the science; we have seen only three cases of the kind, and in these three we did not see the autopsy; we are not aware that many other examples exist in the records of medicine; the disorder of movement which consists in a desire to advance or retire by turns, is, in fact, a very rare phenomenon, at least, in turning over the various works published on disorders of the nervous system, we have been able to discover only a single fact, which we propose to cite in brief detail

In some cases of hemorrhage of the cerebellum, the effusion of blood has occupied one of the peduncles of that organ. Now. it has been proved by the experiments of M. MAGENDIE, that when one of the peduncles of the cerebellum is cut across, the animal, instead of constantly advancing, or retiring, as when the cerebellum is removed, shows a remarkable tendency to the circular motion; he seems incapable of getting on the state of compression of the brail forwards or backwards, but keeps perpetually spinning round on the same centre of parts of the body. Again, eschars are very motion; the body of a patient, who pre- readily formed in persons labouring under sented this rare and curious phenomenon cerebral hemorrhage. If the patient has during life, has been examined, and the le- been confined for any length of time to bed, sion, a congulum of blood, was found in one of the cutaneous integument is very tot the peduncies of the cerebellum. This is a suffer from gaugierne: thus were two

coincidence highly worthy of our attention. although it has existed in one a hgle case only; we know of no other; the case was observed and reported by M. SERGES. The patient, a man, sixty-eight years of age, had been much given to the use of prirituous liquors; after an excess, he was seized with a desire to turn round and round, and when compelled to keep his bed for two months heath, the same som tom predominated; the patient, unable to walk, dowed the impulse under which he laboured, by constantly turning himself from one side to another in his bed.

These are a few of the anomalous symptoms, if we may use the term, which occasionally present themselves in cases of cerebral hemorrhage; but we may meet with complications that should be noticed. Thus some patients attacked with apoplexy are at the same time agitated by

Violent Delirium.

This is certainly a complication and not a regular symptom of the disease. The delirium attending certain cases of cerebral hemorrhage, depends on the existence of inflammatory irritation in the nervous pulp immediately surrounding the apoplectic cell, or on inflammation of the meninges in its neighbourhood. In other cases, instead of agitation and delirium, we observe a state of

Somnolence

different from that which usually accompanies and characterizes bemorrhage of the brain. The patient is plunged in a deeper degree of coma; he is more insensible than is ordinarily the case, and here we commonly find, as a cause of this exaggerated somnolence, a greater or less degree of serous fluid, distending the ventricles, or shed between the membranes lining the surface of the brain, and thus exercising a general pressure upon the organ. We now pass to an examination of symptoms that depend on

Lesions of some Organ independent of the Brain or its Annexes.

We frequently have occasion to observe inflammation of various organs marching with apoplexy, and of course modifying or complicating the ordinary phenomena of that affection. These disorders may be of an acute or a chronic nature. The former generally present themselves with a physiognomy altogether peculiar: their march is very rapid, and the patient soon dies in a state of great weakness and protraction.
This latter circumstance probably depends which influences the reaction in dis

points to remark in connection with certain | terminating fatally, and hence the prognosis complications of apoplexy. 1st. The fa- is in most instances very unfavourable. computations or apopters. 125. In Fig. 18 most instances very untavourable, cility with which inflammation may be developed in several organs, and the great tendency of that inflammation to present itself with advantage symptoms. 2nd. The ing the study of heurorrhage of the nervous facility with which the integuments are struck with gangrene in the parts exposed to pressure. These two points are of on at impositince in practice. They teach you on the one hand to be on your guard against the secondary affections with which your patient may be attacked, and on the dangerous character of those disorders : while, on the other hand, they direct your attention to a state of the skin which, if neglected, may give rise to disastrous consequences.

The Duration of Apoplexy

is very various. However, it is a general principle, that this disease, except in cases extremely rare, does not kill the patient on the spot. In a few instances death has taken place in a quarter of an hour after the first symptoms of effusion. In other cases, which still are to be considered as excessively grave, the fatal termination does not arrive before the lapse of one, two, four, or even six hours. All these cases are more or less rare. In a great majority the duration of the disease is longer; and, however it may be contrary to popular ideas, you may hold it for certain that sudden death is much more frequently produced by a rupture of one of the great vessels of the heart, or of the latter organ itself, than by apoplexy. Indeed, experience shows, that in several cases of sudden death, we can find nothing to explain the immediate cessation of life. We may invent hypotheses to cover our ignorance, we may have recourse to physiological explanations more or less ingenious, but laying these aside as mere conjectures, we are compelled to avow frankly that in some cases we can find no pathological lesion whatever to account for the sudden manner in which life has terminated.

Progress of Apoplexy.

The march of cerebral hemorrhage is almost as variable as its duration. Frequently the symptoms go on augmenting, and the disease progresses gradually up to the moment of death. In many other cases we do not observe this constant march from to commencement of the attack to its end-cers are indepens at different times; the first is it was period much better than poles; and this alternation of amendment the consideration of a considerable length of time; this is by no means i indeed, we may say that hamorriage nervous centres is one of the dis-

centres, your he be prepared to allow several varieties of this important disease. Some of them depend solely on the scat of the lesion. Hemorrhage of the cerebrum different from that of the cerebellum: of the cerebellum from that of the spinal marrow. Some varieties are formed by the nature of the accompanying symptoms. Thus we may have apoplexy with loss of consciousness; we may have it with a perfect preservation of the intellectual faculties, two very different forms, you must allow, of the same affection. Again, other varieties are distinguished, not according to the presence or the absence of some great leading symptom, but according to the intensity of the symptoms in general. This latter is a good practical division, one that has been handed down to us from a distant period. Thus apoplexy has been distinguished into mild, into dangerous, and finally, into apoplexy of a middle character. This is an old distinction, and one that is useful in practice, for it leads at once to an appreciation of the most remarkable disorders. Between the two extremes of " mild" and " dangerous" hemorrhage, may be arranged all the great variety of forms which we have pointed out in the course of the two preceding lectures. Finally, other varieties refer to certain complications attending or succeeding the effusion of blood. Thus some cases are distinguished by marks of inflammation or other disorders in some portion of the nervous pulp. In other cases the seat of the complication is far from the brain, and consists in inflammation &c. of one or more of the great viscera.

TREATMENT OF CEREBRAL HEMORRHAGE.

We have now arrived at an important part of our subject,-the treatment of hemorrhage of the nervous centres. However, our observations on the point shall be concise: many of them are anticipated by what we have already said when speaking of cerebral hyperemia. The chief business of the physician in the treatment of cerebral hemorrhage is to follow and combat the accidents as they present themselves; or the treatment may be considered under another point of view, and regarded as preventive.

Venesection

is certainly the fundamental means on which we should depend. A large quantity of or an narrous centres is the or the pa-cesses most hable to relapse. When the pa-tions has been quoe attacked, he has ge-from the system; we repeat, a large quan-nessity and this, or three relapses, the last tity, because it is important to make a sud-

lation by taking away a considerable mass of the circulating fluid. In general we choose a vein for this purpose, and allow the bleed to flow freely through a large orifice. The good effects of venesection may be referred to two principal circ retances; the first is, that it manifestly opposes the continuance of the hemorrhage into the nervous centres. The second effect is to remove any congestion of the cerebral substance by which apoplexy is so often attended, and thus give the patient a great chance of re-covery from that accident. Again, we obtain no small advantage, by a copious abstruction of blood, from its effect in preventing the inflammation, which, as we have before said, tends to develop itself in the nervous pulp immediately surrounding the apoplectic cell, two or three days after effusion has taken place. Finally, venesection may facilitate the absorption of the coagulum, and thus hasten the patient's recovery by removing the material cause of the secondary accidents. Thus, you see, we can justify the utility of general bleeding in many respects, and you will have occasion to prove the truth of what we have said, when the active exercise of your profession shall call you to apply these principles in practice. Many authors advise the blood to be drawn by opening one of the large veins in the fold of the arm. Others, on the contrary, prefer opening one of the veins in the neck, particularly the external jugular vein; we would recommend you, in all cases, to choose the arm. You can manage this part of the body more easily than any other; you avoid any unpleasant, or even any dangerous constriction of the neck, and you are more sure of obtaining the quantity of blood you desire in a shorter time. Finally, some writers speak of choosing a vein in the foot; but this is an uncertain method of bleeding, and not accompanied with any advantages which can make us prefer it to venesection at one of the veins in the arm. Some of the older authors, and, amongst others, MORGAGNI, recommend us to bleed in the occipital veins, a method by which they say we act more immediately and certainly on the brain, but the practice is now completely abandoned.

Another question that has been discussed is the following; "On which side of the body should we bleed?" should the abstraction of blood be made on the same side of the body at which the loss of motion exists, or should we open a vein on the opposite side? All this seems of very little importance indeed: by bleeding on the side opposite the paralysis, you probably abstract blood from the same side of the body at which the effusion exists, but it is not easy to see cerebral hemorrhage, where we are called how the state of the circulation in the brain immediately after the attack, we should bleed is more influenced by this than if we took once largely; we could say a repeat veneway the same quantity of fluid from the section to the same and the latest bleed.

an and efficacious impression on the circu-| other arm: the general effects are certainly more in proportion to the rapid abstraction of blood, and to its quantity, then to the choice of one vein rather than another. We have already drawn your attention to the importance of taking away at once a leequantity of blood; your first bleeding should rarely fall short of a pound, and may be repeated according to circumstances: the English Mactitoder are in the hight of bleeding very freely; they generally abstract 20, 25, or even 30 ounces of blood at a time, and the effects of this practice seem to justify its adoption. You will find certain contradictions to bleeding freely forced by some writers; thus they say when the face is excessively pale, the countenance sunk, the habit of body feeble and meagre, we should be sparing in the quantity of vital fluid we abstract, and particularly in repeating venesection, but I think we are not to attach any importance to the cir-cumstances just alluded to: it is absolutely necessary to arrest the flow of blood into the substance of the brain, and to dissipate any congestion which may attend the hemorrhage; these two points should dominate all the minor considerations.

Again, it has been asked. "Should we bleed if the attack of apoplexy comes on after a meal, when the stomach is charged with aliments?" Certainly. The presence of alimentary matter in the stomach might perhaps induce you to defer bleeding in cases of a trifling disorder, but in apoplexy, where the existence of the individual is so seriously compromised, we should not hesitate to have recourse at once, and on the spot, to this our fundamental means of treatment.

Having combatted the first effects of cerebral hemorrhage by a copious abstraction of blood from the arm, we must have recourse again and again to the same remedy, according to circumstances : we must keep it in reserve against those symptoms of congestion that manifest themselves at certain periods after effusion has been fully established; we must have recourse to it whenever the appearance of certain phenomena, which have been described in our former lecture, would lead us to conclude that the nervous pulp surrounding the apoplectic coagulum has been irritated by the presence of the lesion, and is about to pass into inflammation; there are no many indications that point out the inde sity of again opening a vein : however, in me remark, that you must proceed? with caution, and observe what may be called middle term in the practice of venescond that when we have to treat a patient who is labouring under the immediate effect of THE PARTY OF THE PARTY.

ing did not answer expectations; but after | ton abstraction of the vital fluid, in the one or two abstractions of blood, practised at a short interval, if the intelligence should still remain obliterated, if the pulse do not rise, if symptoms of reviving conscious-ness do not manifest themselves, beware how you persevere; the further abstraction of blood becomes dangerous, the loss of a few more ounces may rapidly aggravate all the amptoms; the come persists and be-comes more profound, convulsions appear, the breathing becomes stertorous, and your patient, from whom you have taken the slight chance of existence that remained to him, sinks rapidly from the abuse of a means, which, if managed with precaution would have been his safety.

I have more than once seen cares where the whole treatment consisted in the application of a few leeches behind the cars, or to the temples, with the administration of one or two irritating enemata to act as derivatives on the intestinal canal; yet with this simple medication, pursued for two or three days, the intellectual faculties were restored, the come was dissipated, and nothing remained of the cerebral hemorrhage but its almost constant attendant, paralysis of the limbs. These cases prove that nature alone is often sufficiently strong to combat with success the accidents of apoplexy, for we cannot attribute any great effect to the loss of blood abstracted by a few leeches. However, we would not conclude from these that sanguineous emissions are to be neglected; we would only draw your attention to the fact, that venesection may be pushed too far, and that repeated abstraction of blood, in cerebral hemorrhage as well as in various other diseases, may give rise to consequences far from being beneficial.

An excellent work (beau travail) might be composed on

The Abuse of Sanguineous Emission.

Had any of you the time, he would confer a benefit, not only on our science, but on humanity, by showing how injurious have been the effects of venesection when pushed beyond measure, even in the treatment of inflammatory disorders. He might prove that bleeding, when repeated too frequently, in cases of acute pneumonia, instead of cutting short the disease, has, on the contrary, shortened the existence of the patient, who lines mader the loss of blood injudiciously abstracted. We might pass in review the tory of all other affections, and prove the magiscumstance. Diseases, whether acute or chronic, have certain periods; certain is in vain that we would arrest the march mature, or turn her saide from the march she has chosen. The patient, on the other hand, requires a certain degree of force to carry him successively through these several tion of a circular ligature round the limbs; shares; and a successively through by a want it is not easy to see what heneficial affects

onset of disease, is only to leave him without resource at a later period, when it is most imperiously required. Hence, I say, take away a certain quantity of blood in the commencement of inflammation, or of other table for the commencement of inflammation, or of other table for the formation of the formati diseases which require venesection; this is good, this is rational; but if you pass this quantity, you transgress the bounds of a sage moderation, and you injure the patient instead of relieving him. To ascertain this wholesome medium is the difficulty: to decide when we have pushed renesection far enough is a point that requires all our skill, experience, and knowledge; but this is a consequence of the nature of the science we profess. Were it not the case, the practice of medicine would be an easy task, and the healing art accessible without difficulty to the first comer that presented himself.

Arteriotomy.

We have hitherto spoken of abstraction of blood from the nervous system only, but the temporal artery has been frequently opened in cases of cerebral disease, and many writers prefer this method of bloodletting to any other: they think a more powerful impression is made on the system when an artery has been opened. However, this opinion is not supported by a sufficient number of facts to make us abandon the practice of drawing blood from one of the large veius in the arm, a method which we consider preferable in several points of view. An American physician has even gone so far as to open the radial artery, but this is a bold practice, which we would not recommend you to imitate: all the necessary indications may be completely and satisfactorily fulfilled by opening a vein, without any of the inconveniences that obviously arise from arteriotomy.

Bleeding by Leeches.

When a sufficient quantity of blood has been drawn in this manner, we may second the effects of our first one or two bleedings, by applying leeches in greater or less numbers to the temples, behind the ears, to the cervical region, the anus, the inside of the thighs or the vulva in the female: each of these regions has been selected by different practitioners, according to their different ideas, and there are, perhaps, circum-stances under which one may be preferable to another. It is of importance that the patient's head should be constantly kept in an elevated position, and you may also follow up the application of leaches &c., by covering the head with cloths dipped in cold water, or with ice.

Revulsives and Emetics.

Some writers have advised the applica-

can be expected from such a proceeding be adopted in cases of ancient paralysis, but it is made received to have recourse, take care, gentlemen, how you have require as a secondary means of treatment, to re- to it rarbly in more recent cases; the use of valuives of various kinds; these may be stimulants will, under such circumstances. applied in the form of blisters, sinapsema, be calculated to determine a still greater for to various points of the cutaneous intogument; some prefer administering them intermilly: they may then be given by the month, or thrown up the rectum in the form of kritating enemata. Some writers, considerably far removed, we often and it especially the older ones, were in the habit highly advantageous to support the stilength of recommending emetics in cases of cerebral hemorrhage; you will find this, I say, frequently mentioned as an auxiliary in the older works; but must we point out the absurdity of such a practice? Emetics can absurdity of such a practice? Emetics can only be injurious when any determination of blood to the head exists; they are still more dangerous when effusion has actually taken place, and you can easily understand how the muscular efforts that accompany the act of vomiting are more likely to aggravate the patient's condition, than confer a

Treatment of the Paralysis.

We have now to consider the treatment proper to combat the effects of the hemorrhage of the nervous centres. Paralysis is the most frequent and remarkable of these phenomena. Can we oppose any remedy to the modification of movement? Can we hope to combat the paralysis with success? The greater part of the secondary phenomena, and the paralysis in particular, are nothing but mere symptoms; it is not to them that we must address ourselves, our means of treatment are here consequently unavailing. As long as the cerebral substance is compressed by a coagulum of blood, you can easily conceive that we can do nothing for the paralysis, which is its necessary and immediate consequence. Our first and main object must be to favour the removal of this clot, the cause of all the lesions which manifest themselves in sensation or motion. However, when we have reason to think the coagulum has been absorbed, or at least is nearly removed, we must not remain idle spectators of the helpless condition of our patient; we must do something. For this purpose we may apply stimulating sub-stances along the limbs; we may excite the sen administered internally with a good deal of advantage. When the paralysis is of tion of the nervous mass; this second class some benefit by stimulating the muscles, the stons, which we distinguish into hypertres-immediate organs of locomotion; they have pluy of the nervous centres, strophy. In some measure fergotten to act; they have ration, and softening, been enfeebled by long rest, by a forced inbeen enteebled by long rest, by a luroca in-activity, and require perhaps ently some ad-activity, and require perhaps ently some ad-ditional stimulus to restore their power.

which now rather lies dermant than com-spectrance of hypertrophy or ramplises-pactify againstance. This practice than many means; but in the activity and the science,

give rise to the most fatal results. In individuals labouring under the consequences of cerebral hemorrhage which dates at a period by the gentle administration of ferruginous preparations; by a light nourishing diet; by occasional use of mild bitters, &c. In this way we support the constitution under the struggle it has to make, and by aiding nature in her efforts to remove the material cause of the disease we obtain a final triumph.

المحدريس

As to the hygienic measures that should be observed during the course of cerebral hemorrhage, they are exactly similar to those proper for congestion of the brain; it is therefore unnecessary to recur to them on the present occasion. We may now ask Do we possess any

Means of preventing the Occurrence of Apoplery?

Authors have recommended the practice of abstracting a quantity of blood from time to time, in cases where this accident seems likely to occur. It is a good one whenever any of the indications of central hemorrhage present themselves with any degree of clearness; but unless these precursory symptoms exist, it is quite superfluous and unreasonable to abstract blood on the simple supposition that our patient may be attacked with the disease in question. The same remark holds good with respect to the use of the seton and several other means which are ordinarily employed as preventives of apoplexy.

Hypertrophy of the Brain.

We have now passed in review some of the principal maladies of the nervous centres, at least the principal of those maladies which are attended with an organic change of structure in the part. We have successively studied hyperemia of the cerebro-spinal axis, anemia, inflammation, and he-morrhage. We now arrive at a second class, nerves which supply the members, or the in which no organic lesion is found, in which nervous plexuses from which the nerves are given off. In these cases, nux vomics has trition, in a new arrangement of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internally with a market of the walk been administered internal with a market of the walk been administered in the walk been administered cules, without destruction or disors very old standing, it is reasonable to expect likewise comprehends four grand subdivi-

tion or not; hence we are justified in treating them apart. Indeed, for the interests of that are made in the pavement for thrawing the science, we are compelled to treat ramollissement apart from inflammation, for by pursuing an opposite course, we should be compelled to neglect or confound several most important facts. Go to the hospitals, observe diseases of the brain: follow the case of a patient who presents a certain ensemble of symptoms, and you will say that he has a ramollissement of the brain, and not an encephalitis. The former is associated with a train of phenomena with which you are familiar; the latter is not yet fixed in your first saw the patient there was some swellminds, and it is for that reason that we ing of the perineum, which became tender have considered it by itself in the present on pressure. Leeches and fomentations classification of cerebral maladies.

We shall next take up the second portion of our subject, hypertrophy of the spinal marrow. This is an affection which you should distinguish with great care from hyperemia; however, in many cases, as we shall have presently occasion to see, the substance of the chord is pale and bloodless, at the same time that it is hypertrophied. The increased nutrition may, and often does, coincide with increased vascularity, but in several other cases we find it is in connection with anemia. "What are the anatomical characters of hyperemia of the stricture of this rigid kind, is in constant spinal marrow?" This is a question, the danger. He is in great risk of urinary abanswer to which we must defer until our seess, and of extravasation occurring into next meeting.

BY MR. LISTON.

LECTURE I.

GENTLEMEN,-You have had, during the last few mouths, many opportunities of observing the symptoms, consequences, and treatment, of strictures of the urethra, one of the most troublesome and dangerous disexies which the surgeon has to manage. ave had the opportunity of witnessing the cause, and I may even say the formation, of this disease, and of watching the development of the symptoms attendant upon obstinate contraction of the urinary passage of a most unmanageable form, viz., that following injury of the perineum.

we are unable to my whether the immediate years of age, who, while going to his work cause of these two conditions be inflamma- early in the morning, when it was darks slipped his foot into one of those apertures down coals. In some way or other ha struck his perineum on the edge of the opening, and so great a quantity of blood es-caped as to make him feel very faint. About seven hours afterwards he applied to the hospital, when, very properly, a catheter was introduced, or attempted to be introduced, but the instrument appears to have got entangled in some laceration, and a quantity of blood oozed out, although the greatest gentleness had been used. When I were applied, and he was discharged some two or three weeks afterwards, apparently very well. He returned, however, on the 25th of September, complaining of very great difficulty in passing urine, he having been dismissed on the 1st of that month. He was taken back as an out-patient. There was evident hardness of the perineum, and very great difficulty was experienced in passing the catheter; in fact he now suffered under a stricture of the very worst and most unmanageable kind.

Now a patient in such a situation, with scess, and of extravasation occurring into the cellular tissue. He is, from the least excess, liable to complete retention of urine in the bladder, and if that be not most properly and promptly treated, fatal consequences may ensue, or he may be reduced to such a state that his after life will be so embittered as to be scarcely worth retaining. There is, in fact, no disease in which a person. is more apt to be "bungled out of his life," than in retention of urine, whether from strictured arethra or any other cause. But even slight forms of the disease will bring upon the patient considerable suffering, mental and bodily, great irritability of temper, and serious interruptions to the complicated and important functions of the organs attacked, eren impotence, to some extent.

A great variety of disorders of function, and changes of structure, in the neighbouring parts, connected by sympathy or function with the urinary passage, have been supposed to depend on disease in that canal, and to be removeable by putting it into a sound condition. There is much truth in the doctrine, though the treatment must not stop short at that point. Many diseases are certainly engendered or kept up by a disordered and irritable urethra, and the removal of that state enables the surgeon to apply his other remedial means with double effect. Many affections of the CARE.—A man was admitted, J. D., 35 verge of the anus, can be much more readily

y; there is great swelling a of the scrotum and prepace, and ulcershout his glass penis, which for the tent forbid any attempts to introduce truments. He is passing much puriform matter with his urine, which is discharged with great difficulty, and frequently we shall find in such cases a very bad stricture to be causing all the mischief. The testicle is apt to suffer, often becoming swelled in consequence of irritation in the part; the prepuce thickens and contracts; and persons labouring under stricture have more or less uneasiness about the verge of the anus. There is a certain uncomfortable feeling, and a bearing down, great pain, and often difficulty, in passing the stools, and great exertion is called for on the part of the abdominal muscles to empty the bladder; you find also that the bowel is emptied at the same time, there is an evacuation of flatus. and very often of the more solid contents of the bowels. The patients, from the constant straining, are apt to have a determination of blood to the part, they labour under piles, and hemorrhoidal tumours internally and externally, and, very often, there is considetable falling down of the bowel. Other symptoms arise from irritation of the urethra, and among them many painful affections in the lower limbs. Neuralgie often hinge upon urethral derangement, and general and local treatment alike fail, together or combined, in affording relief, until this is looked to and remedien. I have now under treatment a man under thirty years of age, who had been actively treated during at least eighteen months before I saw him. He complained of violent and almost constant pain in the course of the left sacroischiatic nerve. He had been cupped many times, as often as four times a week; he had had blisters and sinapisms applied, and he had tried all sorts of drugs internally; indeed he must have had the stomach of an ostrich to have got quit of the mass of horridly poisonous stuff put into it in the shape of medicine, and he had nearly ruined himself by the purchase of expensive and fashionable drugs, without obtaining even temporary respite. From a highly respectable chemist who supplied the patient, I have a list of the remedies used at various times. It comprised delphinia, strychuia, veratria, aconitine, colchicum, Dover's powder, and, lastly, carbonate of iron in immoderate quantities, though he might, under the circumstances, have, I doubt not, swallowed the chain cable and best bower anchor of a first-rate to hoot, in the form of rust, without being one whit relieved. Such, at least, is my impression. The state of his urinary

matten to sure rate attended to. He labourate and had been up done no from before the neuralgic fitack, under difficulty in passing his water. It came away frequently in a small stream, and with much straining. In the space of fourteen days, and by a few introductions of proper-sized bougies, beginning with a very small one, the pains all but left him, and he is now rubbing in, and it will be with effect, an cintment containing these most valuable of external narcotics, the veratria and aconitine, in the form recommended by Dr. TURNBULL. This is another instance. if any were wanting, to convince you of what I am constantly insisting upon, namely, the necessity of inquiring for, and searching out, the cause of surgical disease, as the first and most effectual means of cure, and doing away with that, if possible, whatever it may be. Pains of a gouty nature in the lower extremities often disappear upon the removal of disease or disorder of the urethra, and many patients have expressed to me their astonishment at the exemption from their usual sufferings consequent upon dissipation and debauch, after their urinary organs had been put into a right condition,

-

The remedy in such slight cases of stricture is readily applied, though, even there, skill and great caution are essential to the patient's well-being and safety. By rash, harsh, or frequent interference, the disorder of function may be increased instead of being alleviated, and in place of a trifting and easily remediable contraction, perhaps only a slight tenderness of some portion of the mucous lining, with irregular action of the surrounding muscles, a narrow and confined stricture may have its foundation baid. occasioning a contraction so tight, as to admit with difficulty and reluctance any instrument larger than a common probe, and surrounded by a substance almost as un-

vielding as fibro cartilage.

does not naturally follow all inflammations, otherwise the great majority of the male population would assuredly labour under this troublesome disease. There are a great many young men who have had gonorrhova, again and again, without experiencing the least difficulty after the cure has been completed, or, in the after period of life, in making wates. Many people are exceedingly liable to gonerrhova, and if they expose themselves to at much, they may peringual themselves to at much, they may peringual or twenty times. I have seen patients when have suffered under that inflictions does not have suffered under that, and still have had it as often as that, and still have not laboured under stricture. The inflam

We were, you may recollect, an which is sometimes the case; and if that the necessity of leaching the perincum on hougie be introduced forcibly, the inflam- than once, of correcting the state of his dimation will run so high, that it will be followed by the deposition of lymph in the celthe lining membrane. But the worst cases hospital, but had not long been in it beof stricture are those which arise from ex- fore he was dismissed. He got doing ternal injury. They may occasionally be some mischief or other, and was discharged, attributable to internal injury. There is also but not before the introduction of No. 8 one case here, by-the-by, which shows recatheter had been effected. I believe when markably well the cause of stricture. Two he went away, he made water perfectly well, very strong reasons are seen, why the man the mucous discharge having ceased. As should have suffered from this disease. Two bad a case as I have ever seen, arose from very powerful exciting causes were applied. the laceration of the passage while the pa-The man was aged 47, and was admitted on the 17th of December 1834. About six years ago, when rigging a vessel, he fell from a height of about thirty feet, and came astride upon a boom. He complained of severe injury in the loins, which was removed the call to make water almost occurred by cupping, but had then no affection of the every half hour. I had him brought from urinary organs, excepting some hemorrhage the country, and most actively treat-from the passage. About four years ago, ed. When a boy at school, he was that was two years after the injury of the perineum, after being over-heated, and drinking a large quantity of cold beer, be was seized with retention of urine. He applied to a surgeon, who forced a large catheter into the bladder, and drew off the urine. This proceeding was also followed by profuse hemorrhage from the urethra. From that time he has complained of pain and difficulty in passing water. Now the cause of the retention no doubt was a stric- confirmed, very likely fresh causes were ture, occasioned by the bruise on the peri- applied, and the passage was inflamed again neum, which perhaps did not attract us actention very much, afterwards aggravated by the dehauch. While over-heated, he what additional causes existed for the stricture when in operation, an external matory swelling of the thickened part followed; then a fresh injury was inflicted upon the urethra, the nincous tissue was individual if nothing else happens, for somevery likely torn up extensively, and this times the symphysis pubis is separated, or was followed by fresh inflammation, which the bones are broken, or a portion of hone terminated in one of the most troublesome enters the bladder, an injury which is strictures I have encountered. He had a almost always fatal within the first 24 copious discharge of puriform matter from hours; and if the patient escapes from the the urethra, and retention of urine occa- dangers of effusion of blood in the cellular sionally supervened, but was relieved by tissue, and obstinate retention of urine, the fomentations. He had been twice under gratment, and derived considerable benefit laid. When I left the Infirmary at Edinburgh. from the measures that were then adopted. I had under treatment a man with very bad Distributes admission, some induration was stricture, the cure of which was materially the along the course of the urethra and retarded by an attack or eryspens or me perineum. The stream of urine was small, face, followed by inflammation of the upper and gave rise to combiderable smarting, part of the windpipe and the fauce, with and sometimes great pain. The urine was opaque, and was discharged, with a great quantity of mucus. A catheter was introduced on two different occasions, and the windpipe of the fauce, with the windpipe and the fauce, with a profuse discharge of purulent matter. (Mr. Coopers had a patient who died after quantity of mucus. A catheter was introduced on two different occasions, and the windpipe and the fauce, with the windpipe and the fauce, with

on will run so high, that it will be fol-by the deposition of lymph in the cel-tissue, or, perhaps, on the surface of the catheter. He get into the service of the catheter had been effected. I believe, when tient was yet a boy. I saw him labouring under dreadful difficulty in making water, and the urine was mixed up with an immense quantity of vitiated mucus. Sometimes the irritation was very violent, and seized with retention of urine in consequence of exposure to cold. The surgoon in the country had no proper instrument with him, and he endeavoured to relieve the patient by pushing in the handle of a spoon, with a small twisted old-fashioned handle, for helping sugar. This operation was followed, not by the evacuation of urine but of blood, and ever after that he had difficulty in passing urine. The stricture became and again. Perhaps he had again and again gonnorrhea. In fact there is no saying causes have been in operation, an external bruise, for instance, when it is lucky for the foundation of the worst kind of stricture is along the course of the urethra and retarded by an attack of erysinelas of the mined for some time, but not so long as and you may recollect that he showed you

ght I never should overto water passed only in drops. 1 a and again to intro ments. I get the catheter fined in the stricture, but by no possibility sould I get it through, and I had determined, as in the case of C. M., new is the house, to cut into the perinous, divide the weather behind the stricture, bring the knife forward, and expose the extremity of the extheter, intro-duced as a guide, and thus be able to pass the instrument into the bladder, and there keep it. He was placed on the table, and tied up as for lithotomy, when I found the stricture yield a little, and on persevering I succeeded in getting a very small catheter into the bladder, and then, so you are aware, the cure was in my power. So in C. M.'s case, by a little perseverance on the day on which I thought of cutting into the perineum, I accomplished my object, and a very rapid and satisfactory cure resulted. I had a young patient, who, before I took charge of the Edinburgh Hospital, had been operated upon there, in whom the stricture was occasioned by the kick of a horse in the perineum-an odd place, by the bye, for such an injury, for one cannot very well understand how the horse's hoof could reach the perineum. The scrotum was bruised, the part behind had also suffered. He richly deserved the punishment, for I believe he had put a furse bush under the horse's tail, and was tickling him in that tender region. He was afterwards further punished. for his perineum was cut into without any object being attained; when he came under my treatment, a catheter was passed, and retained for a short time. I sent him home again, but some hours after be was seized with retention of urine, and he was brought to me in great suffering and agony. A catheter was then re-introduced and retained until a profuse discharge took place, when the stricture yielded. The cure was completed, according to the method which I shall detall by-and-by.

Structure also arises in consequences the laceration of the passage in extracting the laceration of the passage in extracting forced Structure also arises in consequence of stones, or from large stones being force along by the impulse of the urine. We had a case, some little time ago, of false passage in the urethra, a fistalous sperture, through which the greater part of the urine was discharged, after the extraction of a stone. discharged, after the extraction of a stone, stone in pulse on the rectum, for the parts it appeared, from the history of the case, sympathize closely, and are acted upon that the boy had isboured under stricture, by the same muscles. If the stone cause or other. The stone had, When the stricture is pretty well confirmed, comes down from the bladder, and had the satisfact often supposing he has wholly suppose behind the stricture. He was ad-

ngs of this engenemos.) I mitted into an hospital; I shall not say where, as it is not my wish to offend an one (many in the prefession are uncom-monly thin skinned; the stone was on mile about an situh and a half boltind the original lies teak no great one of himself after that Buugles were introduced in order to overcome the stricture, but the opening could not be made to close again. He was admitted labouring under retention of urise, and relieved completely by the employme fomentations; the stricture was dilated; se that Nos. 5, 6, or 7 catheters were admitted readily. The boy did not submit to treatment very well; he was opposed to such means as would have removed the cause, which was the first object, because the abatement of the stricture was essential to the closing of the faise passage. Something more, however, would have been required. But it is very difficult to close up openings which are anterior to the scrotum. I do not know what the circumstances were that rendered an opening necessary, but if it had been possible to bring the stone through the orifice, and by introducing an instrument along the arethra, so as to divide the contraction, without injuring it from without; or, if it had been possible to push the stone back, no such bad consequences might have happened. I caution you against making an opening into the aute-rior part of the canal, for you will find it almost impossible to get the opening closed up again. Had the stone been thrust into the perincum, which it could have been without any risk, and cut out from thence, there would have been no fistulous aperture. I am not an advocate for dividing the stricture from within by the use of cutting catheters or other contrivances, but in a case where the stricture is near the orifice, shmost within sight, I do not think that any injury would result; and certainly an incicision into the perineum would be attended with less troublesome consequences than the incision anterior to the scrotum.

Having said so much to you about stricture, it is time that I should describe to you the symptoms. Slight stricture, especially after the parts have been excited, causes a frequent desire to make water, a scattering of the stream, and occasionally a discharge, a sort of gleet. The patient may apply for relief from some uneasiness in the perincum, or swelling of the testicle; when stricture is more confirmed, there can be very little doubt, from the symptoms its existence. Then the water is passed only in a very small stream, indeed, sometimes, only in drops, and with great straining, his strong impulse on the rectum, for the parts

water run off, in a minute or two afterwards. See, which, being opened, commutes a mixed probably with a quantity of viscial tity, of well-digested but their matter mixed. In state tity, changes take place in the urether, as matter awalling relations when the or well as in the binder. If the stricture and giant is seen through the early of a crimes, the muscular coat of the bladder here comes, the muscular coat of the bladder here comes, the muscular coat of the bladder here comes, mixed with matter of me placement of the place is diminished in capacity, and its mucous spriace is altered, and in the urethra, more especially behind the contrasted part, there is a distation, as may be seen in many pre-parations on the table. You find in a recent specimen the mucous cost always exceedblood. The muscular coat is four or five times thicker than it ought to be. The passage becomes very much dilated, generally speaking, behind the contraction, the necessary result of the stricture becoming tight. Sometimes great quantities of water collect in the pouch thus formed. Sometimes it is like a small bladder, and, not unfrequently, calculous matter collects in it; stones form in the perineum in this way, and it is from this pouch that the water cozes out after the calls to empty the bladder have gone off, and the patient has re-adjusted his habiliments; and if the patient be in the humbler ranks of life, and cannot constantly change his apparel, he is scarcely fit to be approached, for he smells as rank as a polecat.

The stricture, in the first instance, may involve but a very small part of the canal, presenting only such a contraction as might around the passage. But inflammation re--from injections, or from some injury of the parts, either from without or from within; or the urine being obstructed may be impelled against the part with great force, and cause inflammation. Fresh depositions of lymph thus take place, and. ultimately, the limited stricture extends until a hard cord can be felt surrounding the passage, and increasing the contraction perhaps to the extent of an inch, or even more. This hardness in the perineum is found to obstruct the catheter, and you can take hold of the cartilaginous mass in guiding the instrument through the unyielding tissue, and the introduction is only accomplished in many cases after a good deal of perseverance and pressure.

If means be not taken to relieve this direase, alceration is apt to eases in that per of the casal into which the urine is constantly impelled. If the ulceration be laufed, or sloughing occur, there is a risk of The wine being extensively infiltrated in the collular tissue; but, generally, if the urine be not completely retained in the bladder, it escapes, though in small quantities, through the urethra; the parts around the pect, that is, incision of the perincus, urethra become condensed and inflamed; division of the stricture from behind and shecese may come slowly to the sur- wards, when the water was still y

odonr. Often the greater part of the wall will come through this passage, and if the will come through this passage, and if stricture becomes more and more confirm the whole of the water may at last passeo. C patient now under treatment here is some-what in the condition described. C. M., aged 42, was admitted with a fistule in perinco, ingly thick, and loaded with dark-coloured through which the greater part, if not the whole, of the urine, was passed on admission, in the first instance, and that not very freely. When this is the case, the stricture very often yields in some measure. It is not so much excited, as the water is not impelled with such violence against it. This patient had been long under treatment, and at one time great progress was made towards a cure. But, latterly, through his own carelessness, a great aggravation of the complaint had occurred. It was, for months previous to his presenting himself here, found quite impracticable to reach the bladder, with any sort of instrument Caustics and cutting instruments from within had been employed, as is usual, without benefit. We occasionally meet with cases in which one abscess forms after another, and the scrotum is perforated by holes,-six, eight, or a dozen papille presenting in the scrotum and perincum, be produced by tying a firm small cord whole of the water coming through them. I have treated several such cases, external curs, from time to time, from various causes, injury or mismanagement having caused the passage to close entirely, not, however, without cicatrization of the surrounding tissues. Cases occasionally occur in which not a single drop of water has passed per vice naturales for several months. I had one case where nothing passed through the urethra for eighteen months, and I recollect another in which nothing was passed through the urethra for fifteen years. man positively declared that not a single drop of water had passed through the urethra for that period, though he was not very far advanced in life. How he could so long submit to such inconvenience and suffering I cannot comprehend.

What is necessary to be done under such circumstances? I believe that it is only in these cases,—when you cannot by any pos-sibility introduce the catheter,—that you should be under the necessity (excepting also in cases of extravasation) of making incisions into the perineum. I was, in the two cases to which I have alluded, very used afraid lest I should be obliged to put in practice an operation which is pretty aften had recourse to uninconsulty, I amthrough the until n, though in a very shab- violent efforts to pass water, the cavity of by way; but ultimately in both of them the that abscess, connected with the dilatation catheter was, by cantions and persevering efforts, got into the bladder, and a cure was then accomplished without difficulty or de-

I said that gradual ulceration frequently leads to abscess. Here is a very good specimen of it. Observe a ragged hole opening from the urethra into the cavity. specimen was obtained from the body of a very old man who died from the effects of extravasation. The ulceration was recent, and here you perceive is the cavity of the abscess. By the progressive ulceration the matter gradually came to the surface.

But where the urine is retained, and the stricture, from the inflammation within, is entirely closed, a different result follows. Retention of urine, I need not tell you, is very alarming, and very difficult for the patient to bear. The symptoms come on very speedily, where stricture is the cause. The bladder, though not so very much thickened, as in this remarkably beautiful specimen, is, almost uniformly, much contracted, and incapable of being dilated to any extent. It will sometimes contain six or eight ounces of urine, and sometimes not above half that quantity. The symptoms of retention, therefore, come on at a very early period, and consequently the danger is very great. In a few hours after the symptoms have commenced, the patient, perhaps, thinks he is relieved, he feels as if water dribbled away from him, he has a sensation of heat in the perineum, and he is speedily afterwards alarmed on finding a large swelling in the scrotum, urine having got into the cellular tissue in consequence of sloughing of the dilated part of the canal; or the cyst in the abscess having given away by the same process; or an abscess by rapid ulceration, perhaps, has been forming, in close connection with the urethra, by the compression of which the urine is prevented from passing along the canal. You see this happens now and then during the progress of gonorrhoes. An abscess forms and impedes completely the passage of the urine, without any contraction existing in the passage. I had once under treatment such a case of gonorrhoa, the abscess being very deeply seated, in which the urine was arrested in its flow for the best part of three weeks. It is not a good practice to introduce instruments in acute inflammation of the passage, but in that case it was necessary, for ten or twelve days before I saw him, to restored. Now where the patient makes nected with stricture, I shall then make up

behind a tight stricture, is filled with urine, as well as the posterior part of the conel, and the parietes of the abscess give way, so as to permit the escape of the fluid, containing much saline matter, and very acrid, into the cellular tissue. The cyst does not burst, as some writers assert, nor does the urethra; but they either slough or ulcorate. Some patients, with retention, get through by active and judicious management, but a great many are lost, from even slight extravasation of urine. Another very great risk, in all these cases, from such an occurrenceis, that a fatal termination takes place at a very early period, and without time being given for the destruction of the cellular tissue, the urine seeming to act on the constitution as a poison. It is rapidly effused, and attended by a secretion of putrid sanies, with a sinking of the powers of life, and a speedy termination in death.

I should have mentioned before, that we find stricture occurring at various parts of the passage-strictures from injury. The very worst kinds are generally met with in the posterior part of the canal corresponding to the parineum, in the widest part of the urethra; but the atrictures generally met with arise from acute inflammation, produced by the introduction of instruments. or the suppression of discharge. They generally occur in that part of the canal which is anterior to the sinus of the urethra. at three or four inches from the orifice. Strictures occur in the membranous portion of the canal, and they occur also, although not so often, very near the orifice. These are exceedingly unyielding, though why I cannot tell you, but contraction of one part often leads to contraction of another. that the passage is contracted behind, in the membranous portion, and the water does not come away in a full stream; the canal is never fully dilated. Naturally, one of the narrowest parts of the canal is at about three or four inches from the orifice. Here coarctation takes place, and also at the orifice, which is the tightest of all. The whole canal is, to a certain degree, diminished in caliber, and these parts more than any other. The disease very seldom exists singly. Other parts of the canal are generally affected, besides that which is first observed. In most cases you will he able to pass a catheter so far, say, through an obstruction at three inches from the introduce a catheter two or three times a orifice; but then an obstacle still exists day, to relieve the bladder. There was a forther back. Perhaps the commencement orifice; but then an obstacle still quist sort of chronic abscess formed down by the of the membranous portion of the arethra side of the rectum, and it was only when it as badly thickened as the anterior. Before it became apparent, and was evacuated by we next meet, I shall think on the subject incision upon my first visit, that the patient carefully, and if I have now forgotten any got relief, and had the functions of the parts of the symptoms or the circumstances con-

for it. I shall then speak of the treatment. You have seen many cases here, but many more cases are met with in private practice which are not admissible into hospitals, the danger is so very slight. Only the worst cases of stricture are admitted here. It is right that you should understand this, and you should be prepared to treat them scientifically. But there are a great many very difficult cases, for, indeed, many pa-tients labouring under this disease have been " bungled out of their lives " through ignorance and inattention. This drawing represents mortification of the scrotum from extravasation of urine. Patients do not often survive under such mischief, or until the parts become thus disorganized; some struggle through wonderfully, and if incisions be not made, as they ought to be, very early and very freely, the scrotum or the penis is often left uncovered and unprotected.

I should mention that occasionally the passage ulcerates towards the corpus spongiosum, and the urine is admitted into the vascular network, the penis becoming black in consequence. It is not into the body of the penis, but into the corpus spongiosum, that the infiltration occurs. The outer surface of the glans, as you are aware, communicates freely with the spongy body, is, in fact, a prolongation of that tissue. When the glans becomes black, and sloughs, it is about one of the most alarming and fatal signs which we meet with, and many are alarming enough in the disease. This is not a very common occurrence, but Sir Benthree cases in which he noticed it, and in all, the patients, I believe, perished. I have seen the appearance also more than once, but in one of the instances a fatal termination did not happen. The urine may in this way be admitted at once into the blood, and he returned by the veins into the mass of circulating fluid, and thus you can account for the bad consequences which almost invariably follow, but still a fatal result does not uniformly take place.

CURR OF ULCERS.—Dr. Cramer recommends for the treatment of ulcers, that a piece of lint, imband with the discharge, should be dipped in an impalpable powder of the intrate of ailver, and then reapplied to the sec. This he repeats every day, or very other day, and by his enforcing a quiet its applied to head to be a second of the member, he mentions his having stooded to healing the most obstinate ulcers in a period of six or eight weeks. He has fikewise employed the same powder with admittage to the granular conjunctive.—Head State of the second of the same powder with admittage to the granular conjunctive.—Head State of the second of the same powder with admittage to the granular conjunctive.—Head State of the second of the same powder with admittage to the granular conjunctive.—Head State of the second of the same powder with a second of the second of the

JERVIS-STREET HOSPITAL, DUBLIN.

CLINICAL REMARKS

BY

DR. WALLACE.

PRACTURES OF THE JAW.

JANUARY 19, 1836 .- Ward No. 4 .- Here. gentlemen, is a case of fractured jaw in a woman; let us compare it with the one in the man in the ward No. 2: the comparison will be useful. What are the relative situations of the fractures in these two cases? You saw that the man's fracture was situated just at the right side of the symphysis, that it passed between the first and second incisors. And here let me remark, that fractures of the jaw, although they are said to occur at the symphysis, never do take place in that situation, not really in it. This is what you might expect, when you reflect that the symphysis is much stronger than the part of the bone just connected with it, or at the side of it. You remark, that this woman has a fracture on the right side in precisely the same situation as that of the man, but you see she has got a second fracture; the bone is broken on the left side also, immediately in front of its angle. This renders her case far more serious than that of the man. Observe what a difference there is between them. You saw that the man appeared to suffer very little, and there was scarcely any deformity. See how much the fragments are here displaced; remark how this woman appears to suffer, what agonizing pain she seems to experience about the fractured angle, how the least motion of the head annoys her, and how she grasps her occiput with her hand to keep her head steady. She discharges abundantly saliva from the mouth, and is almost quite unable to articulate, whereas the man could speak very distinctly. What is the cause of this great difference in these two cases? I have often observed many of the distressing symptoms which you see in this woman, to arise when the jaw was fractured far back; and I have always supposed them to be owing to the injury of the trunk of the sub-maxillary nerve, which you know enters the bone near its angle, and is, therefore, much ex-posed to injury in such cases as the present, that is, when a fracture exists near the angle. There is also another reason why the double fracture in this woman should produce much more serious consequences than the single fracture in the man. The depressors of the jaw are almost all attached to the middle fragment, while the elevators are connected with the two posterior portions of the jaw; bence great displacement must arise by the different parts of the jaw. You also remark what pain is given, jaw being pulled by their muscles in differ-ent directions. The middle portion is depressed, and the posterior portions are raised, and this displacement is greatly facilitated by the direction of the fractures, which is parallel to the line of direction in which the depressing muscles act, that is, from above downwards, and from before backwards. But in the man's case, the elevating muscles being connected with both fractured portions, the action of the depressors, which are connected with the large fragment, are greatly moderated, and hence there is little displacement.

Now how have these fractures been produced? How has the fracture in the man been produced? By a fall from a ladder on the chin. How has it been produced in the woman's case? By a blow on the left side of the jaw. You can easily conceive, that the mechanism of the forces which caused the fractures in these two cases near the symphysis was different, that is, the force did not act in the one case, as it did in the other. In the man's case, the tendency of the force was to straighten the jaw by pressing the convexity of the chin inwards and backwards, and the solution of continuity close to the symphysis commenced in the inside of the jaw, and extended outwards. In this woman's case, the force being applied to the side of the jaw, the tendeucy of its must have commenced externally, and passed inwards, and most probably the second fracture occurred subsequently to the first, but by a continuance of the same force.

What difference of treatment must be adopted in these two cases? You have observed that the man seems to be very comfortable under his injury; and all that hus been done has been to retain, by a bandage passed under the chin and over the head, cork being previously interposed between the teeth at each side. The same treatment has been adopted, you observe, in this wo-man's case, where there is a double fracture, but you see it does not answer. You see how much she suffers. Now we shall give her great case by adopting the proper mode of treating such cases. The plan is to inthe weight of the unsupported fragment of affects, after a time, either mastication or

whenever I attempt to raise this depressed portion into contact with the upper jaw, or to a level with the other portion. You see she will not allow this to be done; you cannot, in fact, by acting in this manner, either bring or retain the bones in their proper situation, and even if no pain were produced, the mechanism of the parts, and the direc-tion in which the displacing muscle act, would soon render your endeavours unavailing. Welt! what should be done? You must, as I have said, depress the raised part, you must bring it down to a level with the broken fragment; and you do this by interposing a cork between the upper jaw and the raised side, proportioning its thickness to the degree of displacement. You thus depress the raised side, and make it meet the depressed side. I shall now put in this cork at the raised side. See what relief it affords; I shall next pass this in at the other side. You remark she cannot bear it; I must remove it. Now I shall apply a hand-age, as we did in the man's case. This, then, is the mode of treating these fractures. In the one case, you apply a cork at both sides; in the other, you apply it at one side only, and you see how admirably the difference of treatment is suited to the two cases. I should mention to you, that it will sometimes happen, that it will be useful in cases of double fracture to apply a second cork; action was to increase the natural curve of for example, in the present instance we the jaw, and the fracture near the symphysis might apply a cork between the posterior teeth at the left side, not as it was applied between the upper jaw and the depressed fragment, but between the upper jaw and the posterior and left fragment of the lower, which is, as well as the right side of the jaw, kept raised by the elevator muscles. This would keep this portion of the jaw down to a level with the posterior end of the depressed middle fragment. I generally, however, find that this second cork is not nethe lower jaw against the upper; bits of cessary, for there is not in this part so much displacement as anteriorly. The cause of this you will easily comprehend, when you consider the attachment of the depressor muscles.

Let me make another remark to you. You might suppose that as a fractured jaw is subject to constant motion in speaking or deglutition, its reunion would not be easy. terpose a grooved cork at one side only, that The reverse is, however, in general, the is, at the side that is elevated, and then case, and I have often been surprised at the gently apply a bandage under the base of rapidity and satisfactory mode in which fracthe jaw, so as to raise as much as possible tures of this bone unite, even in cases the depressed side. Now let me explain to where from the carelessness and garrality of you the principles of this practice. Look, the patient you might augur the worst. It first, at the state in which the bones are, is really very remarkable how admirably You remark that the portion of the jaw in- nature often works out her object in these terposed between the two fractures is much cases: yet, I have sometimes seen these depressed. This depression is caused, as I fractures remain ununited, and have them have already explained to you, by the con-had occasion to verify the remark of Boyen, traction of the depressing muscles, and by that it is surprising how little the disunion enunciation. Dr. Physick, of Philadelphia, interesting case 4 see what as alteration in succeeded in causing reunion in a case of his countenance, the last when last admitted, he this kind, by the seton. I have also ob- only a few days: when last admitted, he served, on some occasions, union to have etaken place with deformity. Hence, in saying that these cases turn out well, al-though little attention he paid to them, I am making only a general remark, and this must not induce you to pay a lax attention to them

Wast No. 8.—Oh, another fractured jaw! How was this caused? (The house-surgeon replied "that she had been thrown down last night by a carriage in the street, that she was brought into the hospital in a state of insensibility, and that it was supposed a wheel had passed over her head.") Although there is, gentlemen, considerable swelling and tenderness in the fractured side of the jaw, and about the parotid, there does not appear so much injury as would probably have been caused had a wheel passed over the jaw. The fracture may have been produced by a simple fall on the jaw. Let us see where the fracture is: you remark that it is not in the situation of the fractures in cither of the other cases; it is a single fracture, and corresponds to the interval of the first and second incisor of the left side: you also remark the nature of the displacement: the left or smaller portion is drawn outwards, and the larger inwards and backwards. There is scarcely any perpendicular displacement; this is owing to there being elevator muscles attached to each fragment. You remark that she has much more pain than the man in Ward No. 2, but less than the woman in No. 4. You see I can easily replace the parts in their proper position, by pulling outwards the left or smaller portion of the jaw, and by pressing backwards the right portion.

You may suppose, from the facility with which the fractures of the jaw in these three cases have been detected, that their diagnosis is always very easy; so it is if care be taken. You are, however, aware, that only a few days since, a man who had been discharged from prison, came to the Dispensary with an injury of his jaw, and when I told him that his jaw was fractured, he replied that he had himself told Surgeon that his jaw was broke, but that he desired him to go about his business, that there was nothing the matter with his jaw. You see, therefore, that attention is requisite, and upon some occasions considerable attention is necessary, to detect a fracture of he law; for it may happen that there is no applacement whatever, and a crepitus may scarcely be detected by another person.

only a few days: when first admitted, he kept the ward awake all night, as I was in-formed, by his coaring out with the agentizing pains of his hones, and particularly of his shins. He says he now rests most com-fortably: his shins were, on his admission, so uniformly swelled, from the knee to the ancie, that no defined prominences could be felt along the tibis, and the soft parts covering these bones were so tender, that he could not suffer the least pressure to be made on them. You see this is not now the case; there are a number of projections or exostoses, to be felt, and although the whole tibie are still much larger than natural, they feel vastly smaller than they did four days ago. These changes in the form of his legs have resulted from the subsiding of the great tumefaction of the soft parts; all tenderness seems also to have subsided. You see he allows me to make pressure all along his shin. Again, look at his skin; you remark that the groups of shining, scaly tubercles, which were scattered over the surface of his body, and on his temples, have shrunk to a level with the surrounding skin; and two of those which had ulcerated, one on his back, and the other on his breast, have healed. Now what has caused all these remarkable changes in the space of four days? Two drachms of the hydriodate of potash. He has taken half a drachm of this salt daily for the last four days. This is precisely one of those cases of syphilis in which mercury acts as a poison; and this man was half poisoned by mercury before he applied here. The employment of the hydydriodate of potash in such cases as this, is the greatest improvement which has taken place in medical surgery in modera times. This case makes the one hundred and twenty-fourth of secondary syphilis which I have so treated and carefully noted. Two years and a half have now passed since I commenced the investigation, and I have collected as great a body of facts as have ever perhaps been collected, respecting the treatment of any one chronic disease by a particular remedy. I am, I assure you, arranging, whenever I have a moment to spare, these cases, and will commence, before this month is out, to fulfil the promise, which I have long given you, of making them the subject of a series of clinical lectures on syphilis.

DISORGANIZATION OF TISSUES OF THE CALF.

Ward No. 3 .- There is a disease, gentle-Ward No. 6.—You are, I am sure, gentlemen, attending closely to this man's most

ple call, a "flag;" that the skin has a slight | muscles of the trunk of the body, as it were, and leaves a hele so large sometimes, that you could bury an orange in it. We had a similar case in Ward No. 4, a short time ago, in the person of a woman. She had been treated before she came under my care, as this boy has been treated, with poultices, and leeches, and stupes, and was not bene-sted, nor has this boy been benefited by a similar treatment. This affection yields rapidly to mercury, and, as far as I know, to moreousy alone. The woman was materially relieved, just as soon as her guns were affected; and so will this boy be relieved as soon as the slightest action of mercury is perceptible. You see how poor and delicate a looking creature he is: you would say from his appearance that he had improving. The thirst is less pain in head a very bad habit. The woman presented diminished, but the state of lassitude perthe same character of constitution, yet she bore the mercury well, and was extremely benefited by it. I may conjecture, but I do not pretend to say, what the disease is. I have told you its characters, and the manner in which you can cure it.

CASE OF

BMALL-POX COMPLICATED WITH HYSTERIA.

To the Editor of THE LANCET.

Six,-If you consider the following case merits a place in your truly independent and widely-circulated Journal, I shall feel much obliged by its insertion. I have the honour to be, Sir, your obedient servant,

JOHN J. KELSO, M.D. Lisburn, Jan. 20, 1836.

CASE .- J. F., stat. 19, of a stout make and sanguine temperament, enjoying up to the present attack, for the most part, unin-terrupted good health." Dec. 18, 1835, I saw her, and found that three or four days since she commenced ailing, but considering her complaint as only a cold, no treatment was resorted to. She was lying on her right side, in a listless, stupid state, not caring to execute any motion, and apparently unconscious of what was passing around her. Has entirely lost the power of articulation, but appears quite sensible (in the intervals of frequent fits of delirium) of the nature of questions put to her, which she endeavours to respond to by efforts in which the whole | Bemerks, The case just detailed I some

parplish colours. The lag is bent on the become roused into action, accompanied thigh, he cannot straighten it. There is with a deep and powerful inspiration, to be shen much puts in this disease, particularly instantly succeeded by a loud, protracted, when the person stands or attempts to walk, but rather modulated shout. These efforts and unless treated in one particular way, it at pronunciation are evidently teasing, if is remarkably tedious, and often ends in the not actually painful, as she requires to be death of the hardened tissue, which falls out, frequently interrogated before making them. Has severe headache, as evinced by the frequent application of her hands to the forehead; face flushed; skin hot and dig. and there appear a few specks on the chest. probably the eruption of small-pox. Tongue coated with a brown fur; pulse about 100, not full; stomach irritable, rejecting the ingesta, which is chiefly fluid, as there is considerable thirst; bowels constipated. The catamenia has been absent for these last two months. She was ordered a cooling mix-

ture, with a common laxative powder.

22. The eruption of small-pox fully developed, the pustules being distinct, and rather few in number. Irritability of stomuch has disappeared, and the appetite is sists, with a disinclination either to make the efforts at speaking, or to move herself. in bed. Towards the evening there is a feverish access, and the nights are restless. Bowels preserved relaxed by cooling medicine.

26. The articulation is returning, the words, which are very imperfectly spoken. being wholly unintelligible to me, but not so to her immediate attendants. Complains of severe pain in the lumbar region, shooting round to either groin, with a sense of heaviness in the hypogastrium. Face still keeps flushed, and the headache is occasionally violent. Tongue remains coated, but the appetite is unusually keen. Pulse about 90, rather weak. There is globus hystericus, and she cries and laughs alternately,-phenomena which set in a few days back. Habeat emplastr. lytta nuchæ.

back. Habeat emplastr. lyttæ nuchæ.
29. The pronunciation is becoming gradually more distinct and intelligible, the words being uttered at the top of an hysterical cry. There is present some debility, notwithstanding the keenness of her appetite. Sumat Tinet. Lytte gtt. xv ter in die. Vesicat. parv. dextr. mamme; hip-paths.

Jan. 5, 1836. The debility has increased. Bowels have been purged from a dose of the pil sloet, co., which she had taken. The sense of hearing is remarkably soute, and the nervous system generally in a state of considerable excitement. Nights are will restless. Has been taking bitters, wi carb, of iron, &c., for some time.

14. She is gradually, but rather slowly convalencing; some hysterical symptoms still persisting. The catamenia has not yet been restored. The tonic remedies &c. are to be continued.

sider as worthy of relation, by its affording quently observed as an anti-course, where interpeting instruction, especially on two vaccination was according to the course of the course points. First, it evidences a rare example of the supervention of bysteria on the constitutional disturbance that ushers in variols. The violence of the hysteria may be judged from the fact of the complete suspension of the power of speech for the period of six days, and from its slow but gradual return to its wonted state of perfection, which it has now nearly regained. That the occurrence of this phenomenon was owing to the hysterical affection will hardly be questioned, since the existence of the latter was both then, and subsequently, unequivocally demonstrated by other phenomena that could not be mistaken; such as the wild, loud, and hysterical cry, with which she attempted to speak, the alternate crying and laughing, oftentimes immoderately, the exalted excitement of the nervous system generally, as evinced by a marked acuteness of hearing, amounting even to pain when words were uttered rather louder than usual, and an especial sensitiveness of the whole surface of the body, with globus, &c. But the question here occurs, whether the development of the hysteria is to be attributed to the pyrexia of the small-pox, or to the amenorrhoes, which, as has been seen, had existed for a period of two months. That the hysteria did not at least immediately originate in irregularity of menstruation is pretty evident, from the circumstance of the derangement of the uterine function persisting during even established convalescence. Its development may rather be referred to the fever, the system possibly having previously taken on the predisposition from the above, in conjunction, perhaps, with other causes. But although the vast importance attached to deranged uterine action as an exclusive, or even a chief, origin of hysteria, is justly exploded, it may still be considered as acting, to say the least, not altogether an unimportant part in its excitement as a predisponent cause. Hence its regulation, if possible, in all systems of treatment, should form, as it has formed with all enlightened practitioners, an indication, in every case, of primary moment.

Next, it adds another instance to the too many that are already on record, that vaccinia does not ensure a complete exemption to the system from a subsequent attack of variols. In proof of the genuineness of e variola in this case, notwithstanding the presence of a distinct vaccine indentathe on one of her arms, I may simply enuon that ushered in the eruption, the regularity of the progress of the latter to maturity and decline, coupled with the fact of each vesicle exhibiting the characteristic central desensive and distinct, cases are not unfre- on the living economy.

vaccination was never

It may not here be out of place to state, that for the last year, and better, small-pox has prevailed spidemically, so an alarming extent, in Lisburn, and in the country for many miles around it, attacking indiscrimi-nately the vaccinated and the unvaccinated, the old and the young. It exhibited itself chiefly under the confinent form, and the number of fatal cases were uncommonly large, occurring, principally, as they did, in those who had never undergone vaccination. It was observable, too, that in all the cas which were vaccinated, and were afterwards attacked by variols,—and these were a considerable number, -it ran its course both more mildly and speedily, the mortality being comparatively trifling, the vesicles still presenting their distinguishing characteristics. But from the fact of vaccinia being thus found inefficient, in all cases, as a preventive to infection, the common people have considered the having recourse to vaccination as useless, and the opinion has extended, and is extending, propagated as it is, in particular places, by some of its officious, if not influential members, that safety alone resides in inoculating with the variolous virus. Thus in some parts inoculation has been practised rather extensively; and although, generally speaking, the result is more favourable, the disease passing through its course more mildly, yet instances of a more fatal termination are by no means rare. Besides, the practice cannot be too much reprehended, as it not only tends to abuse the public mind against what yet must be considered as a valuable substitute. but operates injuriously on society, by the propagation of a dreadful, and we would fain have hoped, a banished scourge. Viewing, however, as I do, vaccinia as an admirable and still efficient security against variolous infection, under particular circumstances, it may not be improper to mention what those circumstances are; and in doing so I only reiterate an opinion, subject, so far as my experience goes, to no exception, not lately advanced, and which has, of late, become rather popular, that when considerable febrile commotion is excited in the system, with inflammation in the course of the absorbent vessels and glands, in the in-oculated extremity, and the evolution of pustules, either round the original vaccine one, or on other parts of the body, (phenomena which fully demonstrate that the systen has been influenced by the vaccine lymph.) the most implicit reliance may be placed on its adequacy as a preventive mean against all subsequent infection. It were useless to search after any other sufficiently pression. Although it must be confessed that valid test of the geneineness of vaccine in this case the cruption was not very ex-lymph, than its demonstrable tangible effects

744 MR SAMUEL ON GONORRHEAL RHEUMATISM.—DR. FERGUSSON

With regard to the treatment of the case, there is little worthy of remark agound the fact that, as no remedies of an active nature, for combatting the hysteris, could be had recourse to during the progress of the small-post, it was left to take for a time its own post, it was see to take our a require own course. This was the more to be regretted, on account of the mallimina appearing when the cruption was about beginning to decline, as this would have been the proper time for reacting to those remedies best calculated to click the catamenial discharge, the ac-complishment of which would have proved, doubtless, an important preliminary step towards a core; but the taking advantage of nature's effort, at that time, by any active treatment, would hardly have been justifiable. Subsequently, considerable debility set in which demanded a tonic system of treatment; and as the restoring the healthy tone to the system was considered the best emmenagogue, few remedies portaining to this class were resorted to. The practice of irritating the mamme, recently so much owing to the debility then present perhaps it had not a fair trial.

RHEUMATISM FOLLOWING GONORRHŒA.

To the Editor .- SIR, my attention having been drawn to a statement published in THE LANCET of Saturday, January 16th, respecting gonorrhoeal rheumatism, I bog to say that I think this disease does not in all cases arise from the administration of copaiba. There is at present a man in the North-London Hospital labouring under this dis-case, and who has been there for the last two or three weeks, and on my questioning him, he strongly denies ever having taken any of the above medicine. The treatment adopted by Dr. Elliotson in this case, consists in the exhibition of hydriodate of potassa, with manifest advantage. The most peculiar symptom in this case is a severe pain in the soles of the feet. The following is a short account of the symptoms peculiar to this form of disease, extracted from some rough notes taken at Dr. Elliotson's lectures at the University, when on the subject of rheumatism. "Rheumatism is very much predisposed to by gonorrhea. This sort of rheumatism always affects the feet. It may affect the knees and hips also. It is also a very obstinate form. With this rheumatism there are generally attacks of superficial inflammation of one or both eyes. It is not iritis, and it is not purulent, but it is attended by copions watery secretion. Some persons never have gonorrhom without this secretion."

There have been several other cases of this form of disease in the hospital during the last year, all of which have been successfully treated by the hydriodate of potassa. Should any other cases occur, I shall not fail to make inquiries, the result of which I will forward. I am, Sir, your obedient ser-Vant

J. B. SAMURL, Bendent N. L. H. Vanzhali, Jan. 23, 1836. a

MEDICAL AID FOR THE SICK POOR. PROPOSAL FOR ITS SUPPLY ON EQUITABLE PRINCIPLES.

To the Editor of THE LANCET.

Sta,-Having been lately requested to sign a protest of the general practitioners in medicine of this part of the country, against the misrepresentations of the Poor-law lauded as an important means of eliciting Commissioners, -which, although in no way the menses, through its acting sympatheti- interested, except as the advocate of justice cally on the uterus, proved ineffectual; but and humanity, I had great pleasure in do-at the same time it is right to state, that ing; and having for many months must listing; and having for many months past list-ened to endless discussions, and read an infinity of remonstrances, and letters, and complaints on the subject, I still think that the main points and strength of the case have been overlooked, and therefore should you think this letter of an impartial bystander worth publication, I beg you will give it a place in the first spare corner of THE LANCET.

Every one will admit that our Government must have been actuated by the laudable desire of ensuring proper medical attendance to the sick poor of the country, and it remains to be seen whether their agents. the Poor-law Commissioners, have adopted the proper steps for effecting that national object, or whether they have not, on the contrary, sought to slur over the calls of true humanity, and, as I shall presently show, by practising on the fears of the established inedical officer, driven bargains with him, and, on degrading terms, exacted an amount of duty which never can be rendered with the effect sought to be obtained, because in their rage for union and centralization, they have in many instances removed the sick poor as effectually beyond his eye, and out of his reach, as if the object had been to deny them all medical assistance whatever.

It has ever been easy to be charitable at the expense of others, and the game has too often been played of seeking populty ap-plause, to the prejudice of justice. When the Poor - law Commissioners therefore claimed credit for economical reform, by advertising for the lowest tenders, and calling up the inexperienced needy adventurer from the schools, in want of a place, to un-

derbid the established practitioner who had I tion which its enactment would afford. I do long been in charge, they handed over the sick poor to serve the purpose of the former's unprincipled speculation, or held him up in terrorem over the latter, with the view of imposing conditions upon him which he never could execute in fairness either to the unfortunate paupers or himself, but which, in order to preserve the practice on which he subsisted, he found himself chilged to submit.

This surely was intimidation and not justice -far less could it come under the denomination either of charity or humanity, and as it must be the aim of every parental government to protect all classes of its subjects, the numerous medical practitioners throughout the land have a right to invoke its protecting shield against their present oppressors, and this can be extended to them effectually, only in the way of a national enactment, providing medical attendance in every parish for all the paupers, whether sick or well, in the list, on equitable terms, at so much annual cost per head, and then the Commissioners, by selecting and appointing the best, instead of advertising for the worst, may exercise, and under proper regulations enforce, that humanity to which they were so falsely laying claim

As a contract, take it in what way you will, always implies eventual gain to the contractor, every system of tender and underbidding must be bad, and in the long run the sick poor must be the only sufferers. The system I advocate, were it fairly entertained by the legislature, would be national, humane, and just to all parties. It has for ages, under certain modifications, been practised in the army and navy. It was, as I have witnessed, executed with the test effect amongst all communities of negroes throughout the West Indies, and I can conceive no good reason why, midatis iautandis, it may not be brought into operation amongst the pauper population of Great Britain. One mighty advantage would be the simplification of accounts, of regulation, and of duty. All would be comprehended, without confusion or dispute, under one principle of action; and if the reciprocity of compensation and duty be justly poised, the sick poor would be duly cared for, and the medical attendant not degradingly, because not unjustly, rewarded. Any other plan than this must be fraudulent, as laving claim to charity, and that too without effecting the object, at the expense of the medical profession, while it cannot to involve the members of this last in perual contest with the poor-law authorities; they are seeking to impose, and the other to avoid, impossible duties, and all to the prejudice of the poor. This would be clear and intelligible to every one, and should it appear so to the profession, I hope

not here enter into details to prove the foregoing, or to show first the h est established practitioner of every parish, from his know-ledge of the pauper's character, and the responsibility for his own, must ever be the fittest in the first instance, and should never be employed out of its bounds, or at beyond his best, for the sick poor require to be protected signing neglect, as much as their doctor against oppression; but I see ready to do so should my statements be dis-

Having, of late, avoided the topic, and ceased to read upon this tiresome subj (for nothing is so tiresome as the reiterated language of unredressed grievance), I really cannot tell whether the above proposal may not already have been laid before the public through some other channel; if it has, this letter will be superfluous; but if otherwise, its publication in THE LANCET may probably, in some degree, serve the cause of the profession. I have the honour to remain, Sir, your most obedient servant,

W. FERGUSSON, M.D., Impector-General of Hospitals, H.P. Windsor, Jan. 20, 1836.

MEDICAL POOR-LAW CONTRACTS.

LETTER FROM MR. RUMSEY.

To the Editor of THE LANCET.

Sin,-I have perused the leading article in THE LANCET of Saturday last relative to the mode of making medical contracts in the Poor Law Unions, and beg, in reply, to assure you that much as I should rejoice to see some decisive step taken to bring the present state of parochial medical attendance under the notice and investigation of Parliament, I should not feel justified in coming forward as you propose, to call a public meeting of the profession in London.

My reasons are as follow :-

1st. In my official capacity, as Secretary to a Committee consisting of eleven members of the Provincial Medical Association (residing in eight different counties of England and Wales). I could, of course, do nothing without their joint approbation and direction.

2nd. I am quite uncertain whether their. approbation to such a measure would be obtained, or whether they would consider themselves authorised to act in a manner not at all contemplated in their original appointment, which was for a specific object, viz. to report on this matter at the next anniversary of the Association.

3rd. It is also very doubtful whether a public meeting in the metropolis would they will arise, as one man, to seek the protec- ascertain the feeling of the great body of country practitioners, very few of whom indentures were returned to me, and I im-could attend, and still fewer could remain mediately left the table. Thus, having pregenough to enter fully into the subject, Which requires a particularly careful and calm discussion.

My own opinion with regard to the best course to be pursued on the occasion is, that I have ascertained that their indentures associations of medical practitioners should forthwith be formed in every county or district, similar to those in Berkshire, Buckinghamshire, Sussex, the Wealds of Kent, and East Kent,-that meetings should be held by each association, for collecting evidence relative to the working of the present system; for devising the most effectual means for a remedy; and for taking immediate measures to bring their views before the consideration of Parliament, either by petition, or by direct communication with their local representatives. It might also be desirable for each association to appoint one or two deputies, who might meet thrown out be milibratorily refuted by Mr. in London, and who, being fully prepared Smith himself, and the certainly ought to nofor the discussion, might agree, with affect, tice it, it will warrant the charge that his re-

However, as I am desirous that your recommendation should have full weight, I from our consultation worthy of your knowledge, I shall not fail, with your permission, affair. I am, Sir, your obedient servant, speedily to inform you of it.

As the appeal to me was public, perhaps my reply should likewise be so. I have the honour to be, Sir, your very obedient servant.

H. W. RUMSEY.

Chesham, Feb. 1st, 1836.

CONDUCT OF THE APOTHECARY EXAMINERS OF MR. SMITH.

To the Editor of THE LANCET.

Six.- I trust the interest which you have always shown in the cause of medical students generally, and in the case of a late rejected candidate for the apothecaries' license, especially, will extend to an early insertion of this letter, as it touches very materially upon one point in the report of his case.

It was stated by the Chairman at the meeting at the Crown and Anchor, and again reported in your journal, that in the course of the examination of Mr. Smith, the indentures of the candidate were produced by the Secretary, Mr. Watson. I presented myself on the same evening as the gentleman alluded to. The proceedings commenced by each signing his name, testifying that all the certificates he had produced were correct. After this, and previous to the commence-After this, and previous to the commence- and I certainly ought to have commented upon the ment of any one of the examinations, my statement at the meeting.

ceded Mr. Smith, I did not see whether his were returned to him; but from others who have passed the Hall, and, among those, one who presented himself on the same evening. were returned after the same manner as mine. Now in my case, as in others, my examiner could not have perused my indentures a second time, unless I had voluntarily produced them, or Mr. Watson or some one else had picked my pocket while my attention was so very auxiously engaged; and in that case one or two circumstances must have taken place: either the candidate or his foster tutor, Mr. Meade, has made an incorrect statement, or the indentures must have been retained specially for the purpose of their production in the manner described. If the array auggestion which I have thrown out be satisfactorily refuted by Mr. on some plan to be submitted to the Legis- Section was premeditated, and that animosity was entertained towards him by the examiners, ending in an act of foul injustice. If Mr. Smith vouches for the truth of the statehave written to all my colleagues on the ment, the Secretary to the Society of Aposubject, and if anything should transpire thecaries will afford, as a matter of course, an explanation of this most extraordinary

INVESTIGATOR. London, Jan. 28th, 1836.

MEDICAL MAGISTRATES.

Sin,-As the champion of the general practitioner, I address myself to you on a subject which interests our profession. I understand that the Lord Lieutenant of this county refuses, most peremptorily, to hear of any application made to him on the part of any member of the medical profession, for an appointment as magistrate. Has his Grace's elevation precluded him from knowing that this class of his Majesty's subjects is as well educated and more generally informed than most others, and that their conduct, their habits, and their means of acquiring a knowledge of mankind, are not excelled by those of any other? Upon what ground, then, does his Grace object to the medical practitioner? We know, for we have had many examples, that any illiterate retail trader whose success in business has enabled him to become possessed of a freehold property of the value of 100%. per annum. professing Tory principles, has no difficulty of mounting the bench.

The latter gentleman has been engaged as private thor sofficiently long to be well aware that the pro-duction of the indentures could be only computable with great leregularity in the customs of the court,

San Branch Land

Angold law which excused medical men from serving on juries, and performing the duties of parochial offices &c., and which was then intended as a boon, has of late years been converted into a reproach by the ignorant. The office of coroner was formerly frequently held by the medical practitioner.

I am very happy to see by the late municipal returns that many of the towns have appointed medical men as councillors; and I trust that, ere long, our body will take that station in society, and assume that importance, to which its intelligence and moral character entitle it. I am, Sir, yours &c. MEDICUS.

London, Jan. 23, 1836.

PETITION FOR REMUMERATION AT CORONERS' ENQUESTS.

To the Editor of THE LANCET.

Sir,-I take the earliest opportunity to inform you that at a Committee meeting of the Berkshire Medical Association, held this day at the Reading Dimensary, the following petition was prepared for presentation to the House of Commons. I am directed to request that Robert Palmer, Esq., will do us the honour to present it, and also to furnish a copy to all the members in the county, with an carnest solicitation of their support. I have the honour to be, Sir, your obedient servant,

GEORGE MAY.

Reading, Feb. 2, 1836.

To the Honourable the Commons, &c.

The Petition of the undersigned Medical Practitioners resident in Reading and its vicinity, and in other towns and villages in the county of Berks,

Humbly showeth,

That your Petitioners have been at all times willing to further the due administration of justice in their attendance on Coroners' Inquests.

That the duties which thus devolve on your Petitioners are highly important and responsible, requiring the possession of extensive knowledge, and the devotion of much time and anxious labour.

That your Petitioners are advised and believe, that the law in its present state does provide a remuneration for their services at

Coroners' Inquests.

Sec. 3.

Pret your Petitioners respectfully appresel your Honourable House, with the temperate but earnest language of complaint and remonstrance, humbly beseeching you to supply a remedy against the injustice which they thus suffer, and to enact the award of such equitable remuneration as in your wisdom may seem meet.

And your Petitioners will ever pray, &c.

ALDERSGATE SCHOOL OF MEDICINE.

LETTER FROM DR. CUMMIN.

To the Editor of THE LANCET.

Str.—My name having been very un-ceremoniously introduced into your last number by a writer signing himself "An Attendant at the Aldersgate-street School," you will perhaps allow me to set this person. right with respect at least to his principal misstatement.

The fact is this. When I quitted the theatre on Wednesday last, after lecture, found in the museum a student who said he wanted to put a question to me, and hoped would answer it. I assented. Upon which, to my surprise, he began with, "Understanding, Dr. Cummin, that you are part editor of the Medical Gazette, in which an article has appeared "———. I at once cut short has appeared "---the speaker to demand what right he had to address me in that form; I pointed out to him the impropriety of his conduct, and added that it was highly impertinent in him or anybody else to impute to me the authorship of any article appearing without any signature in the Medical Gezette.

Such was the whole amount of what passed; Mr. Skey and Mr. Furley, who were present, can vouch for the truth of what I state. The latter part, consequently, of your anonymous correspondent's letter, beginning with, "It is but just to Dr. Cummin," &c., is totally unfounded—pure and gratuitous fiction. I am, Sir, your obedient W. CUMMIN.

servant,

February 1st, 1836; 21, Great Russell Street, Bloomsbury.

Dr. Cummin having submitted to our perusal the preceding letter, we can guarantee the perfect correctness of the statement which it contains.

F. C. SKEY. EDWARD FURLEY. Aldersgate School of Medicine; February 1st, 1836.

THE LANCET.

London, Saturday, February 6, 1836.

Two or three weeks since we were instructed to believe, by the hirelings of the corruptionists, that the draft of the charter of the new Metropolitan University was in a state of forward preparation, and, moreover, that the preliminary labour had thus | verified, and they may now, perchance, if for been executed by the exemise of medical they be not totally blind, discover, that in reform. The charter was to be out in a few the very hesitation of the executive, is to a partisans of the two chief medical corpora- ciently evident that the advisers of the no person beyond the precincts of the Privy may have been the number of snares set for Council Chamber, who can obtain a glimpse their discomfiture and betraval. ter had been left to be settled quietly in hourers in the work. Even if their evil charter long since would have received the their plans, we can assure them, will not be sign manual of the King, and a precious adopted, so that neither from their heads nor charter in all probability it would have their hands will any auxiliary aid be sobeen. Not that the Ministers have no de- licited or obtained. sire to do justice to the public in this transtution was designed to effect.

the intellect prevailed on this subject in the studied silence, experience having but too Cabinet, we insisted on the production of a long proved that arrangements in medical draft of the intended instrument, and we government which were suited to the feelnow unhesitatingly contend that the prero- ings and practices of our two detested gative of the Crown with respect to char- medical colleges, would at once be spurned ters, is grossly abused, and brought into with indignation by nineteen twentieths of public odium, when it is exercised accretly, the profession. A popular liberal governin consummating measures which affect ment would hardly trust, in so important an the general interests of the people. If undertaking as that of founding a new nothing wrong be intended, whence the University, the rump of that most intolerant necessity for concealment? But the mere faction, which, even now, by its prejudices endeavour to carry on the work secretly is and higoted conduct, is daily throwing an proof, a priori, that something wrong is in-additional burden of degradation on the tended. If Charters are to be privately governing councils of the Colleges of Phyconstructed, why also are not Acts of sicians and Surgeons. Throughout the pro-Parliament? days, and its machinery was to be set in ac- be found one of the best proofs of the tive motion by the wily fabricators, and the bonesty of the Ministers. It is now suffitions. Yet there is no charter, and there is Crown have not been entrapped, whatever of such a document. Let us hope, then, events, it will be found, ultimately, we apthat discussion, exposition, and a little salu- prehend, that the opponents of instituting tary agitation, have been productive of some a liberal University in this metropolis, will advantages to the community. If this mat- not have the misfortune to be the chief laholes and corners by the intriguers, the genius have been consulted in the design.

Although we were told, again and again, action, but because it is quite clear, from that the charter was near its completion, what has already transpired, that they were yet no hint was given of what would be its not acquainted with, or had not sufficiently conditions, and the friends of the new ininvestigated, the laws which the new insti- stitution were exposed to the incessant torture of conjecturing its contents. There Anticipating that some such obscurity of was much of discretion manifested in this CHEQUER and his colleagues. But it oc-The monopolists of our colleges must be curred to us that they stood in need of some

precipitancy, - that a simister influence his honesty of purpose, that there exists on might establish and work out the governing the part of the executive authority an erdent principle, and the dangers were magnified love for the diffusion of knowledge, said; in in our view by supposing that the well-the pursuance of that great and divine obmeaning founders commanded but a very imperfect knowledge of medical law, and of of contempt and defiance towards every inthe multifarious circumstances which are connected with the existing chartered corporations. The contrivers in this instance, on both sides of the question, have appeared to imagine that it is as easy to manufacture and set in motion a new metropolitan University, as to puff out a soap-bubble, and float it in the air. The minds of these persons, bowever, it is evident, have not been applied to the most intricate or weighty parts of the subject, or, possibly, the most active of the advisers of the CHANCELLOR of the Excuequen have consisted of two descriptions of persons,one anxious that the institution should be imperfectly founded, in order that it might experience a speedy downfall,-the other, less anxious regarding the general interests of science and the community, than for the success of one or two favourite institutions. Placed between the clashing views of individuals whose minds were thus biassed, the Ministers have not had an easy duty to discharge. The delay, therefore, which has occurred in executing it, must induce every unprejudiced person to believe that they would not willingly lend themselves to forward the sinister schemes of either faction. We still hope and believe, therefore, that the advisers of the Crown will go straight forward in their undertaking, fearlessly, boldly; disregarding the threats of enemies on the one hand, and the interested entreaties of friends on the other. A more glorious opportunity for founding a national institution, dedicated to literature and the sciences, even offered itself to a body of enlightened statesmen, and as the enemies of reform have conceded a principle, difficulties there can be none where there is found comprebuttelveness and vigour of intellect.

We are presuming, however, that there

ject, that there shall be manifested a display dividual who presumes to occupy a position which is detrimental to the hopes and prosnects of the majority of the nation. If the new institution be based upon just principles, it will not so much be the University of London as the University of the Empire, whose inviting portals will receive without distinction the sons of genius and intellectual industry. If it be designed to give an impetus to the progress of knowledge, why, we ask for the hundredth time, should its utility be lessened, its splendour be clouded, by the imposition on students belonging to certain schools, of a peremptory curriculum? The system of education should remain as free as the air; and the certificate system, as it is at present carried into operation between the schools and the colleges, ought to be annihilated for ever. What is it, in fact, but a tax which operates probibitory of honours, of fame, and of fortune, against the natural talents and prospects of the poorer members of society? This question should be answered unrestrainedly by every advocate of the certificate system, and if the answer contain no refutation of the principle for which we contend, let us have an institution which shall be devoted to the interests of the nation, and not dedicated to the sordid interests of a monied aristocracy.

IN THE LANCET of last week, we inserted a note at page 727, signed " An Attendant at the Aldersgate-Street School," in which reference was made to the alleged disclaimer of a Dr. Cummin, that he was in any way connected with the trashy thing printed every week, called " The Medical Gazette." A note will be found, on the same subject. in the present Number of Pair Laucer, from Dr. W. Comment himself. In this last production, there is a contradiction of a spectable names, which were attached in the nortion of the statement which was con- pages of THE LANCET to many of the best tained in the one first published. But what is to be inferred from the remainder of the printed in the English language. In the epistle? We put the question, in order that it may be answered by the party who is most deeply interested in the affair. Be-. fore, however, any reply can reach us from that individual, it is our bounden duty to inform Dr. W. CUMMIN, that it has repeatedly been stated to us that he is the BRODIE, he treated general practitioners as condutor of MacLEOD in printing the at- a "subordinate" class of men, and-not tacks which systematically appear in "The stopping there,-with a malignant coward-Medical Gazette" against the general prac- ice never equalled in the annals of literary titioners of this country. medical productions that had ever been eyes of the Editor of "The Medical Gazette" (the poor devil was whipped to his work), a knowledge of the science of medicine and surgery was confined to " hospital" physicians and "hospital" surgeons. Like his friend and colleague BENJAMIN Gazette," the statement of RODERICK MAC-LEOD was true or false, it has not been

ever may have been the writer of "The the stain which still lodges upon his repu-Gazette," whoever may have been guilty of the baseness and cowardice of attacking the private character of the Editor of THE LANCET, because that Journal was strenuous and persevering in support of the rights of thousands of English surgeons against the encroachments of the Colleges, and the insults offered to them by the functionaries of the Hospitals, the slanderer succeeded in destroying his own; at any rate, of causing the bare suspicion that any man could be the author of so much infamy, to be converted into the means of his own professional ruin. When Rope-RICK MACLEOD ceased to be the Editor of "The Medical Gazette," we know not; but we believe that the most that can be said of him at present is, that he has the opportunity of administering " bread pills " to some of the patients of St. George's Hospital. He is one of the sufferers in that establishment. His fate is redolent with instructive warning.

But to return to Dr. W. CUMMIN. The contents of his note, we tell him frankly, are of a suspicious description. He has taken a step which requires that he should advance farther, or sink back at once into the abyss of odium in which the report of his being connected with "The Medical Gazette" had thrown him in the minds of the students. There is no escaping from the dilemma but by making an unqualified declaration that he has no official connection with the editorial department of that production. Unless he be in a condition to publish such a disclaimer, he will probably spare himself many years of anxiety and fruitless toil, by at once taking his departure from this metropolis, and returning to his native country. Neither the soil of England, nor the feelings of the bulk of his professional brethren, will be found at all congenial with his professional pursuits and interests. We trust, therefore, imputations which are thrown out against that the next communication of Dr. W. the purity of that gentleman's motives in CUMMIN will be sufficiently expurgatory of attending the meeting, is one which charges

tation. Already he seems sensible that the bare suspicion of his connection with the editorial office of "The Medical Gazette," demands the substantiation of a contradiction offered under his own name, by the testimony of two witnesses. He has already made a true estimate of what must be the certain consequences of a connection with the pestiferous and odious journal in the pages of which the signs of cowardice, falsehood, and malignity, have been regularly traced by the pen of a concealed lowminded slanderer.

In the notices which have appeared in the journal so frequently named in the course of the foregoing remarks, of the great meeting of medical students held at the Crown and Anchor, the consistency of that work, in its love of calumny, is strikingly apparent. Not content with falsifying the conduct of the gentleman whose temperate and admirable behaviour conferred a dignity on the deliberations of that assembly, which could not have been adequately derived from any other source, the maligner of the students, the defender of the unjust conduct of the Apothecaries' Company, the systematic advocate of the abuses of our hospitals, and the corruption of our corporations,-this contemptible slanderer of the bulk of the English medical profession. must necessarily display his vinerous poison in making an attack upon Mr. Liston, only because that distinguished surgeon was present at the meeting, and, by his presence there, showed that he sympathized with the insulted students, and was desirous that their privileges should be placed upon a just and secure footing. In taking part with the students, Mr. Liston has committed a heinous offence, and he must therefore be made the subject of a certain portion of vituperation. Accordingly, amongst the

hist with having been actuated by a follow doubt can be extertained of his perfect facility with one of the aggricular parties capability to undergo a fair and impartial "Wis there," says the slanders, "any gramination. And from whom did he obtain his information relative ing for the rejected student a public examito the "rejection" at the College of Sur- nation before an impartial public tribunal. meons? Why does he conceal the facts? Such a scruting is now claimed by Why! Because a simple statement of them would overwhelm his employers with disgrace. True, a student was lately rejected at the College of Surgeons, after two pretended examinations. And under what circumstances? The young gentleman had been upwards of six years in the profession, and his time had been thus bestowed;-

He was five years the private pupil of a distinguished hospital-surgeon in Edinburgh.

He had been nine months dresser in the Royal Infirmary of Edinburgh.

During nine months he was the clinical clerk of the surgeons of the Royal Infirmary.

During eighteen months he was physician's clerk in the same institution.

He regularly attended all the medical classes in Edinburgh, and constantly dissected during long periods in Edinburgh and London.

This contleman was rejected. Because he was not qualified? No. But, as we be-Heve, and probably as the profession will believe, because he had been the private

racter, if he be not instrumental in procur-THE CANDIDATE, AND WE ARE AUTHOR-IZED TO MAKE THE DEMAND PUBLIC. The candidate is ready, willing, and solicitous of proving that he has been the victim of injustice, and all eyes will now be directed towards the parties who are stigmatized with being his persecutors. Had the young gentleman been a private pupil of any one of the surgeons either of St. Bartholomew's Hospital, St. Thomas's Hospital, or Guy's Hospital, had he been clinical clerk to either of those surgeons, or had he produced an enormous roll of "certificates" from the surgeons of either of those hospitale, who can or will believe that he would have been rejected? Had he been placed under the circumstances just stated, some eight or ten very simple and ordinary questions would have been asked, and there the scrutiny would have terminated; but in the case of this young gentleman, a thrust was to be made at Mr. Liston, whose appearance in the metropolis has disturbed the nerves of the whole of our "consulting" surgeons, with the exception, probably, of Sir ABTLEY COOPER and Mr. WARDEDS. pupil of Mr. Liston, and thus the perse. The fame of Mr. Liston has already excuted student was made the medium of tended throughout Europe, as an operator attacking the character and reputation of and a pathologist, and, placed as he was, at the teacher. The pre-eminent qualifier the moment of his arrival in this metropolis, tions of the candidate are well known. No by his previously established fame, in one of

the most prominent places in the first man language of the states the sanction of his profession, no art, no contrivance, no of his doper to some of his nonsensical hymisrepresentation, of which the menonolists can be the authors or the inventors, can have the effect of checking the course of his brilliant and successful career. On the confrary, the attack which has been directed against him in the person of his pupil, is an acknowledgment of his reputation and power. It is a concession which the force of genius has extorted from prejudiced and tainted minds, and were it not for evidence of this undoubted and unquestionable character, we might be incapable of judging to what extent or to what purposes the minds of the hospital surgeons of this metropolis had been excited by the honourable appointment of Mr. LISTON to the office of surgeon in the hospital of the "University of London."

In publishing the lotter of Mr. Rumsey, (page 747) we have only to remark that his plan would be perfectly unexceptionable were there time for carrying it into execuadvocates of the system. One of them tion. We hope, therefore, even yet, that cither himself, Mr. YRATMAN, or some other taneous affection, from adopting the treatgentleman who has devoted his attention to the subject, will act upon the suggestion! in the last number of THE LANCET. It is quite certain that there is not now sufficient time to form county associations, whose opinions could be brought to bear with sufficient effect on the decisions of Parliament. If the meeting were convened in the metropolis, Mr. Rumsey would find that many hundreds of medical practitioners would be present. It is a question in which the entire medical body takes a deep interest.

The disciples of HAHNEMAN are becoming as numerous in this metropolis as, and not EDWARD IRVING, and, apparently, from the same cause, that is to say,

potherer, through first seducing their assent to some common-place principles which all admit to be incontrovertible. Whatever is new in the homosopathic system evidently is not true; and whatever is true, may be found in medical writings from the days of Hyppo-CRATES to those of SYDENHAM, or from the time of Sydenham to that of Cullen.

Since writing the above remarks we have received the following statements from one of our reporters. We beg those members of the profession who may think the matter worth a moment's consideration, to remember that the "new" light is not that of Acmecopathy simply. The proper name for the mania is HAHNEMANISM.

The discussion at two of the metropolitan medical societies at their last meetings have ended with remarks on the subject of Hahnemanism, Dr. Uwins bringing it forward in the Westminster, and Mr. Kingpon in the London Medical Society. Both those gentlemen seemed to think that it would be well for the profession to inquire into the merits of the new doctrine, particularly as "a number of influential merchants and had lately experienced some relief in a cument of a German doctor, and had wholly dispensed with the attendance of the surgeon to the family, because that gentleman which was submitted to the profession declined to treat the children on the homeopathic principle!" Mr. KINGDON related other cases of a similar kind. He certainly considered, he said, that it would be proper, from the influence the system had obtained over the minds of many very intelligent men in this metropolis, to prove its merits. We have heard that "the new system" is a subject of common talk "on 'Change." Dr. Uwins states that he was convinced that Dr. Quin, one of the Hahnemanists, was not likely to he led away by imagination or charlatanic views. He was also in consultation with Dr. DARLING a short time since, when that gentleman ordered three minims of the liquor ammonia acetatis in a mixture for a child, asserting at the time that he had found it exert more diaphoretic power in such doses than in larger.

It was also stated by a Member of the London Medical Society that several of his more so than, those of the late wild-headed patients had placed themselves under Hahnemanists, and that he knew two physicians of eminence who, after being unshocessful the in the treatment of several cases, recom-

A Manuel of Experiments liberrative of Chemical Science, systematically arranged, &c. By John Munaar, F.S.A., P.L.S., F.H.S., F.G.S., &c. 3rd Edit. London. Highley, 1836.

THE author of this little work is a kind of admirable Crichton in his way; there is no article of the encyclopædia that he has not written upon. Appended to the volume before us are notices of not less than fifteen treatises by the same author on subjects London Hospital, Whisechapel, an association relating to chemistry, natural history, ckperimental philosophy, medicine, navigation, theology, and the inferior mechanical

The opusculum itself is an epitomized epitome of chemistry, a selection of the plums from the pudding, a means by which, without the pains of thinking, any idle fellow may attain a sufficient modicum of practical chemistry to astonish young ladies and little boys. Every mamma, happy in clothing before they can leave the Instituthe possession of a son with an uncommon genius for the explosion of squibs and crackers, and the ignition of prosphorus, cannot do better than present him with this important volume.

, NEW OPERATION TABLE .- Those who are familiar with the scenes of confusion. and know the want of system, which daily prevail in the majority of the operating Theatres of the Metropolitan Hospitals, will feel much gratified by inspecting an apparatus, which has been contrived by Dr. Verren, a model of which is now at the Admiralty. In conducting surgical operations, we generally observe either a most ostentations and ill-timed display of instruments, or an affectation of simplicity of means for accomplishing the intended purposes, so that when any unforeseen accident occurs during an operation, the requisite instruments are not at hand. The ingenious contrivances of Dr. VEITCH obviate space not only a Table which is well adapted for all surgical operations, but having un-the day. Dr., or rather Mr. Faraday (for demeath the table, and invisible to the patient, a set of compartments sufficient to fere with the full acceptance of the Oxford

coops | contain every kind of surgical instrument. The table is so contrivad that the head of the patient can be elevated to any angle, and its length may be altered according to the height of the patient. The compart-ments are each marked with their particular contents, so that any assistant can at once supply the operating surgeon with whatever instrument he may require. Although Dr. VEITCH, who is an experienced Navy Surgeon, has designed this admirable table for the use of surgeons of the Navy and Army, yet it is equally applicable to all public Hospitals, and may be most advantageously possessed by all medical gentlemen in extensive general practice.

HOSPITAL SAMARITAN SOCIETY.

"There has existed for many years at the of extreme utility, most highly creditable to the projectors, styled the Samaritan Society. Its object is the relief of circumstances of distress in persons presenting themselves at the hospital, which cannot be provided by the Institution itself. For instance; domestics who have been obliged, by sickness or accident, to quit their places, when discharged from the hospital, are frequently without the means of support until other places can be procured. Many patients are so destitute as to require partial tion. Many are natives of distant parts, and, without assistance, would be unable to reach their parishes. Immmerable inducements exist for the formation of a society of the like nature, in connection with the North-London Hospital. Time, however, has not been afforded to organize a plan, though a subscription for the purpose was set on foot soon after the opening of the bospital, the disbursement of which has been judiciously attended to by the Matron (Mrs. Hunt), to whom, until the Society is formed, it is respectfully requested that contributions (most acceptable, however small the amount) may be forwarded." We add. our most cordial recommendation of the object, to the humane.

ROYAL INSTITUTION.

Friday, January 22, 1836.

BILICIPICATION OF PLANTS.

This was the first meeting, for this season, of the members in conversazione. all those difficulties, combining in a small observed amongst the visitors many of the most distinguished literati and illuminati of diploma by this gentleman), selected for the could not macerate, or, in any other way subject of this evening's lecture, the changes illustrate, the organic versuable dirange effected in fossil plants, which process he, ment, without in area. in common with Dr. M'Colloch, has called the efficification of plants.

Siles or silica, or, in common parlance, flint, as the professor said, is one of the most common of substances; it abounds in sand, in clay, in crystal, and in various earths; it also circulates in, and is secreted by, hiving plants, as, for example, the grasses. The properties of this substance are very suitable to so general a constituent of nature; it is insipid, inodorous, and resists the action of ordinary reagents. It also resists, to a greater degree than any other compound substance, the influence of heat. Mr. Faraday has never succeeded in reducing it to a gaseous form, and is disposed to think the experiment quoted by Dr. M'Culloch as fallacious. As Dr. M'C. succeeded in only one instance in sublimating the silica, probably the presence of calcareous matters might account for the deposition on the surface of the receiver. Silica may be reduced to a very fine powder, and the lecturer exhibited a quantity in a state of extremely minute division. It is, as already intimated, union with a common alkali; when thus fles our curiosity. united, it is soluble in water, and it may be precipitated in the form of gelatine, by the wood were kindly furnished for the occasion addition of an acid. This gelatine contracts by Mr. Brown, the celebrated naturalist, in dimension as it solidifies. The proper and Sir Francis Chantrey, the distinguished subject of the lecture was the silicification of sculptor. plants, or that delicate and unexplained process by which the original matter is removed, and supplemed by siliceous deposit. This process of substitution has nothing similar to it amongst any of the phenomena of nature;

finitely greater degree. Several examples are extant of fossilized woods, both of the endiganous and exogenous classes. are proserved in all stages of growth. the germ to the mature tree, and in all d grees of decay, even to the most fragile touchwood. What is remarkable, is the conservation, not only of the actual solid, but of the area of the vessels, which are filled up with white, or semi-transparent agate. In the decayed woods, the deficient parts are also represented by the same kind of agate. Dr. Turner has formed an hypothesis for the solution of this interesting process. He supposes these fossils to be formed in such situations as are exposed to the action of silica, dissolved in the alkalized streams of water, which are sometimes met with. Many considerations are opposed to this supposition. These fossils are al-ways produced deep under the surface of the earth, away from the influence of air and water; the theory of infiltration will not account for the fossilization of such very tender and perishable parts as the seminal ministe division. It is, as an easy moments permane parties as the same a compound body, consisting of an element leaves of a plant. The infiltration of these called silicon, and oxygen. This silicon is a plants would, as far as our present know-brown metalline body, not acted upon by ledge of physics intimates, require many water,-a circumstance in which it differs years for its completion,-a circumstance infrom other bases of earths. Silica, with the consistent with the accurate preservation of exception of calx, is the most general con- evanescent structures. Mr. Faraday is of stituent of nature; it constitutes almost the opinion, that we have no knowledge whatentire of flint, agate, calcedony, amethyst, soever of the nature of this process. He and each crystal. Flint is discovered in thinks our only mode of inquiry must be great abundance in the fissures of the confined to an examination of silica, in chalky strata, being distributed in lamina, order to an exposure of some of its occult which lie occasionally parallel to those of properties. A careful search also may detie chalk, and occasionally dissect them at velop some specimen of fossilization, where various angles, entring up the chalk into nature has been impeded in her proceedrude squares, rhomboids, and other matherings, and her nostrum betrayed, the change matical forms. Nodules of silica, in the form being exhibited as it were in transitu. The of agate, are found in the middle of other instances of recent fossilization, which have stones, where it exhibits a beautifully crystalline disposition. In calcedony, a form are mere incrustations of calcareous or even of silex familiar to many, the soft character of siliceous matter, where there has been no of the outline shows the substance to have preservation of organic forms, none of that been once plastic. One character is pecu- beautiful and incomprehensible substitution, liar to silica, that of forming glass when in which, while it excites our admiration, baf-

LONDON INFIRMARY FOR DISEASES OF THE SKIN.

(From a Correspondent.) - A public meetit is so particularly delicate, that the botanic ing of the friends of the above-named insticharacter of the plant is perfectly preserved, tation, in aid of its funds, was held on Mon-all the vessels, fibres, &c., being in form and day evening last at the Committee Room, colour an exact transcript of the original 51, Great Ormond Street, C. Carpue structure. The most skilful manipulation Esq., F.R.S., in the chair. The venerable obsirmed appeal the business of the meet- scalp. She was however, discharged, quite ing with the able address, explaining the ob- well, on the 22nd of Jan. 1835, and remained jects of the institution, and exercestly in- in good health until the evening of the ture, since its revival, having been hitherto defraved by the medical officers. He stated his expectations, that if well supported by the public, it might, ere long, equal in public utility the great hespital of St. Louis in Paris,—and mentioned the researches which had been lately made by Dr. Litchfield, and some of his colleagues, on the itch insect, the existence of which had been fully demonstrated by him.

The secretary, Mr. BRENT, then read a report on the state of the charity, which had been the means of relieving a great number of patients, in many of whose cases a complete cure had been effected. He stated that he had great hopes of public support in behalf of the infirmary, and that the attention he had received in his canvaes in the immediate neighbourhood, and the interest its re-establishment had excited there, had greatly exceeded his expectations. He read letters which had been addressed to him from the Duchess of Kent and the King of the Belgians, who have been graciously pleased to extend to it their patronuge, and also one from Sir John Conroy, announcing his assent to become a vice-president, agreeably to the request of the Committee.

A number of gentlemen added their names to the list of subscribers, and it was determined that the present meeting should be only preparatory to one on a much larger scale, to be held shortly at the Thatched-House Tavers, or some other public room, at which the president, or one of the vice-presidents, should be invited to take the chair.

NORTH-LONDON HOSPITAL.

ERYSIPELAS OF THE HEAD,-REMARKABLE EFFECTS OF THE EXTRACT OF BELLA-DONNA

MARY PROES, aged 32, was admitted under the care of Mr. LISTON, on the 21st of January, labouring under severe erysipelas of the head and face. The patient was admitted into the hospital on the 30th of October, last year, for a similar attack, affecting the same parts; she was then very successfully treated with tartarized antimony, incisions, and fomentations. The attack was probably not more severe than the present one, in the first instance, but it had been allowed to proceed for four days without the administration of any remedy. The convalencence was rendered rather tedions, from collections of matter forming in various parts of the stated that she had fallen on the point of

viting its friends to come forward promptly 20th of Jan. 1836, when having left the house in its aid, almost the whole of the expendivery thinly clad, she suffered considerably from the cold. During the same night she was seized with rigors, which were succeeded by heat, pain, and tingling of the head and face: on the following morning her face was so much swollen that she could not see. On being brought to the hospital on file afternoon of the 21st, her whole face and scalp were enormously puffed. and very tense; her eyes] were completely closed, the pulse 110, the tongue covered with a thick yellow fur, bowels open from medicine. She was wild and restless, and her hearing appeared to be morbidly sensible; she answered questions put to her, in a vague and hurried manner. Fomentations were applied, and a quarter of a grain of tartarized autimous in some saline mixture was given every hour.

22nd. Has passed a restless night, complains of the pain being more smarting; pulse 100; tongue still furred but moist, She was now ordered a mixture containing one grain of the extract of belladonna in sixteen ounces of water, of which two tablespoonfuls were given every three hours. The eyelids to be freely punctured, and to continue the fomentations. A ring of the nitrate of silver was drawn around the neck.

23. Very much improved, has passed a good night; the swelling and redness are greatly diminished, the surface appearing wrinkled; pulse 96; tongue still furred; bowels open. The patient says she is very much better. A small quantity of pue, which had collected over the right parietal bone, was evacuated.

24. Rapidly improving; swelling and redness nearly gone; pulse 96; bowels not open; to have a dose of house-medicine. Convalescent; discontinue the mixture.

In going round Mr. LISTON remarked that this was one of the most satisfactory and successful cures of erysipelas he had ever seen, the disease entirely, though not suddenly, disappearing in the course of a very few days. He was inclined to attribute this to the treatment, both local and general, which had been adopted, but more particularly to the administration of belladonna. This, the students might be aware, was given ; on the homeopathic principle, the doses only being somewhat increased. They had all probably seen the good effects of the aconite, and some of the other remedies employed by the advocates of homeopathy.

DISLOCATION OF THE HUMERUS ON THE DORSUM SCAPULA.

This rather unusual accident lately occurred at this hospital, to a woman, who he right shoulder. The humerus was disocated on to the dorsum of the scapule.

The following symptoms presented themhe following symptoms presented themnelves:—A hollow underneath the accountes,
and a large firm tumour, resembling a small'
range, on the dorsum acspulse, beneath the
spine of the bone, and which moved on rosating the humerus. The arm fell nearly
perpendicularly, the elbow pretty close to
the side. Mr. Moaron, the house-surgeon
reduced the dislocation, by an assistant fixang the scapula and grasping it with both
ands. Extension was then made by Mr.
M., from the hand with the arm held out at
ight angles with the lody. The head of
the bone returned with a very audible snap.
The arm was then slung, and fomentations
were applied to the joint.

To the Editor .- Sta,-Having been absent for some weeks in the country, my attention has only been lately directed to a paragraph in your journal, referring to the note of mine which you did me the favour to insert. You may remember that the note in question related to the numbers of the pupils in attendance at the new anatomical school in Kinnerton.street. I stated that there were 42 bona-fide pupils, independently of others to whom the lecturers, had given tickets. It appears that you have received several letters impugning this statement, and implying that the number of bona-fide pupils is not so great as I represented. Now, Sir, I repeat, upon my word of honour, that what I stated is strictly correct, and that the number of gentlemen who have actually paid their money for their tickets does amount to forty two. Besides these gentlemen, twenty-three others are in attendance, making in all sixty-five. As my accuracy has been called in question, you will, I am sure, permit me thus publicly to repeat my assertions, and again to refer to the books which lie on the museum table, as evidence of the correctness of my statements. I am, Sir, your obedient servant,

JAMES EVETT. Kinnerton-street, Jan. 27, 1836.

ERRATUM.—To the Editor.—Sir.,—I have observed an error of the press in my letter which appeared in the last number of your journal. The last few lines of the second sentence ought to have been as follows:—Because they have not like himself been sedgeed into attendance there," and have not gratified by an "exorbitant fee" the fraudulent extortionacy of its "governors or functionaries." The words between inverted commas are, as nearly as I can now recollect, those used in the letter to which mine was written as an answer.

I should feel very greatly abliged by your noticing the above defect. I am, Sir, yours obediently,

Rosser Davier.

King's College, Peb. 3rd.

The letter we believe was printed as written.

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications to Mr. Warley may be addressed to him at his residence, 35, Bunroad Square.

In a notice of "Andral's Clinique" a short time since, we stated that the price of Dr. Spillan's translation, published by Renshaw, acarcely exceeded that of the original work. The following correction of this observation should have been made in the ensuing number: The French edition is published at forty france, and is sold in London at forty shillings; the Brussels edition is sold in London at thirty shillings; br. Spillan's translation, when complete, will sell at twenty-five shillings, being five shillings less than the foreign edition.

A Non-Professional.—The prevalence of such an "opinion" is news to us. As a matter of form, perhaps, the custom is abating. Its uses are numerous.

One of the Meeting.—The proposal would be right enough, but the parties would, unfortunately, have to struggle against the law by its adoption.

A Medical Apprentice.—Conformity with the custom ought not to be rendered compulsory, and then, whenever voluntary compliance is yielded, the terms of a proper agreement would unquestionably be obeyed. Doubtless a change will be made in the law.

We have found it impossible to insert this week the letter of Mr. Prater, and in order to give the whole of the St. George's Hospital proceedings at once, we must again defer our report from the board-room of that institution.

We will insert the letters of A Suffolk Practitioner, Mr. Bedingfield, and K.

The letter of Mr. Carmichael appeared at page 714 of our number for January 30. The very earliest opportunity was taken for giving it insertion.

We are requested to point attention to an advertisement on the cover of this week's Lancer announcing the first meeting of the attend.

Mr. JAMES BAKER (whose letter was not received until a very late hour) wishes us to draw attention to an advertisement on the cover of THE LANCET, containing some particulars of a petition which he has prepared to be presented to the House of Commons, praying for the enactment of a law charles, it was very natural for him to be both on-which shall award a just proportion of remuneration to medical men for devoting from all participation in his proceedings, and to actheir time and services in the elucidation of ke facts at coroners' inquests.

Mr. Sorwith, in a reply to the letter of Mr. Way, " must distinctly states that Mr. Way did not, at their first interview. distiaim any authority as a member of the Commitfor the course he was pursning, but that on Mr. Sopwith's refeast to comply with his request being clearly given, Mr. Way did use the threat stated in Mr. Sopwith's last letter, and," Mr. Sopinformed, that he is entitled by law to make the
with adds, "in a tone of voice which was evidently claim in question, but there is no law which enables intended to convey more meaning than the words ex- him to support it.

med. To show Mr. Way," Mr. Supwith precent that neither the prospect of exclusion from all for a sanifical meetings, nor the denial of priffusions when meeded, would induce me to forget the coin me, but that gentleman was too far lings of chaptin at my cool refus tween the morive which induce twalfy to thank him, and that expression of which is meant to convey a sense of obligations real favour conferred. That Mr. W. much surprised at my referring to his conduct the whole of his professional prethren, I call the Whote of me provisional metairen, a can reading believe, for, hergeting the had overstepped the lies prudence in his capacity of committeeman, and caractly expecting that a practitioner of only two mouths standing in the place, would presume to re-quest an explanation of his conduct before the nonsowledge that he had acted upon his own responsibility alone. With such an explanation the members of the Association were of course satisfied, hav-ing nothing to do with Mr. Way's private motives or actions as unconnected with them."

Mr. Sopwith's letter is dated Jan. 20th, but we have not before been able to secure room for any portion of it, a circumstance which has caused as regret. The insertion of several reports and communications is unavoidably postponed for a week.

A Constant Reader of THE LANCET is

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

BITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculte de Médecine of Paris.

LECTURE XI.

HYPERTROPHY OF THE NERVOUS CENTRES.

Gentlemen.-We have now to enter upon the study of a class of nervous discases different from those which have hitherto occupied our attention. We have to lay before you the history of hypertrophy of the cerebro-spinal axis, of its atrophy, of ramollissement, and, finally, of induration; after having completed the history of these four lesions, we shall occupy ourselves with lesions of secretion.

Let us commence with hypertrophy of the nervous centres. This lesion may be scated in any one point of the cerebrospinal axis, in the cerebrum, in the cerebellum, the medulla oblongata, or any portion of the spinal chord; however, we shall take for our type hypertrophy of the cerebral hemispheres, and describe the anatomical characters of that lesion, observed in this part of the nervous system, as applicable to the whole.

Hypertrophy of the hemispheres of the cerebrum is distinguished by the following

Anatomical Characters.

The nervous substance is firm and dense, and opposes unusual resistance to traction; its colour is, in general, more pale than common, and the hypertrophied tissue does not contain any considerable quantity of blood. DANCE was one of the first who wrote The lerion may occupy the whole mass of the upon this subject : you will find an excellent hemispheres, or it may be partial, occupying

memoir of his on the history of hypertrophy of the brain in the Repertoire d'Anatomie, published by M. BRESCHET, vol. 5, where the pathological anatomy of this disease is described with great minuteness and fidelity. The nervous tissue, as we have just said, scems to contain less blood than natural, and when you divide the cerebral substance into slices, you observe but few of those small reddish points which are ordinarily disseminated through the nervous mass when in a normal condition. Thus hypertrophy may exist without hyperemy. It is not an excess of blood which forces the nervous molecules to occupy a greater space than is natural, but the increased bulk depends on an augmentation in the number of those molecules themselves.

When you divide the substance of the brain, the cut gives a dry even surface, which does not present that humid aspect natural to the brain. The same appearance is observed externally; the superficies of the brain is in like manner dry, and it would seem that the normal exudation of fluid which takes place from the arachnoid and pia mater, has been either diminished or suspended. The convolutions are flattened, and approximate together; there does not seem to exist any space between: the latter circumstance is readily explained by the pressure exercised in consequence of hypertrophy. The membranes are closely applied to the cerebral surface, and seem as if they were too tight for the organ which they envelop. The ventricles are, as it were, effaced, and we observe no tendency whatever to effusion within their cavities. The nervous mass, developed beyond measure, seems to occupy the place left, by all the compressible parts yielding to make room for it.

We may now follow the lesion which we have just briefly described, through the different portions of the cerebro-spinal axis. Examples of hypertrophy have been observed in the cerebral hemispheres, in the cere-bellum, in the spinal marrow. We propose to study the lesion in each of these portions of the nervous system, apart; and lat for

Hypertrophy of the Cerebral Hemispheres.

No. 650.

but a small portion of the nervous tissue. | the causes of the Icsion now under consider-We shall put on one side the latter species, to consider it at the end of our lecture, and occupy ourselves exclusively at present with general hypertrophy of the hemi-spheres of the brain. When the augmentation of volume thus comprises the totality of the cerebral mass, two cases may present themselves, which it is important to distinguish, depending on the relative proportions of the hypertrophied nervous substance, and the osseous case in which it is enclosed and supported.

In the first of these two cases, at the same time that the brain, in becoming hypertrophied, tends to occupy a greater space, the osseous parietes surrounding it are equally developed, and we may form an exact estimation of the size of the brain from the magnitude of the cranium. In the second case the brain is hypertrophied, as in the former, but the osseous cavity does not show any tendency to develop itself; the dimensions of the skull are normal, while the relative size of the brain is greatly increased. It is necessary to distinguish carefully these two cases; for, in the first, we may have no accidents which betray the abnormal augmentation of volume in the brain; the skull being developed in the same proportion as the cerebral mass, we can have no compression, and the case may go on for a great length of time, or even to troubled in a notable manner.

In the second case, which observation has shown to be much more frequent than the first, the osscous parietes do not follow the exaggerated volume of the nervous tissue; hence the brain is necessarily subjected to an habitual compression, and various accidents may ensue; instead of the symptoms of compression, we may have those of irritation or congestion, and their numerous accompanying phenomena, all depending on the greater or less degree of disproportion between the containing and contained parts, between the cranium and brain. So much for the pathological anatomy of hypertrophy of the cerebral hemispheres. You see how it gives a key to many of the symptoms of this affection, and you will not fail to observe the utility of the arrangement we are accustomed to follow in this and our other courses, in which a description of the morbid appearances preceding the history of the disease, and its symptoms, leads you naturally to anticipate a great number of points connected with it, or at least prepares you to understand more perfectly the history of its march, phenomena, and terminations.

Can we ascend to a knowledge of

The Causes which favour Hypertrophy of the Cerebral Hemispheres?

We are compelled to acknowledge that trouble in the economy.

ation are completely, absolutely, unknown. Congestion of the brain has been mentioned as one of the exciting causes of hypertrophy; this may be the case, but we are not in a condition to prove it; in theory, we might admit that the frequent repetition of hyperemia is calculated to produce an hypertrophy of the cerebral substance, but, on the one hand, remember how paleness is one of the anatomical characters of this alteration; while, on the other hand, we have not observed any trace of hypertrophy in a great number of individuals who for a long time had been subject to cerebral congestion. It has also been affirmed, that long-continued and energetic action of the brain, particularly exercise of the intellectual faculties, may give rise to the development of hypertrophy of the cerebral hemispheres. Some writers assert, that on examining the heads of intellectual persons, of individuals remarkable for some great intellectual faculty which they possess in a high degree, the organ of the brain corresponding to this faculty or power exhibits an excess of development, a true species of hypertrophy. This may be the case; it is even probable; but truth compels us to say that it has not yet been demonstrated. We have the more difficulty in admitting the rapid development of any cerebral organ in connection with its activity, as physiology the end, without any of the functions being teaches us that nutrition goes on much more slowly in the nervous pulp than in the osscous or muscular tissues, and that we cannot in any way establish an analogy between what takes place in this latter system, as a consequence of long-continued exercise, and the development of the brain, or any portion of the brain, in persons accustomed to laborious mental occupations.

Hypertrophy of the nervous centres is not a disease common to all

Periods of Life.

Thus we are not as yet acquainted with a single case of this lesion observed in an individual who has passed the age of 35. All the cases recorded in the annals of the science, refer to persons below the age just mentioned: it has been seen at from 30 to 20 years, and even at a much earlier period of life; in one case recorded, the patient was a child five years of age. Let us now study

The Symptoms

which accompany hypertrophy of the cerebral hemispheres. In the first place we have to remark that this lesion is sometimes unaccompanied by any symptom whatever's this happens when the osseous parietes are developed at the same time, and equally, with the brain. Here compression does not exist; we have no irritation, no cause of congestion, and the abnormal development of the brain does not produce any notable

communicated to us by M. Scouterten; you will find it in the Archives Générales de Médecine, t. 7, p. 31. It was that of a child five years old, whose head had acquired a degree of magnitude equal to that of an adult. This augmentation of the skull had taken place gradually: however, the intellectual faculties were not at all troubled; the child did not differ from others of the same age: there was no modification of sensibility or motility worth mentioning. This child died from acute inflammation of the bowels. After death the head was examined; the substance of the brain was found considerably exaggerated, especially in the nervous mass situated above the ventricles, and the parietes of the skull, a little thinner than usual, were developed to a size corresponding with the increased bulk of the brain. Here then is a case where the lesion of which we treat was not announced by any symptom.

Lesions of Intelligence from Hypertrophy.

Whenever hypertrophy of the nervous centres is not accompanied by a proportionate development of the cranium, we have a series of accidents produced that may reasonably be referred to irritation or compression of the nervous substance. These accidents may be distinguished into lesions of intelligence, of sensation, and of motion. When the hypertrophy is established in a gradual and slow manner, the intellectual faculties become dull and obtuse. In all the cases which are cited by authors, and in those I have had occasion to observe myself, this diminution of the intelligence existed. Several patients were reduced to a perfect intelligence, but preserved it in a weakened form, and fell from time to time into a transitory state of imbecility. In other cases we find a perversion of the intelligence: the patient becomes delirious, or sinks into alienation of the mind, and mania. Thus you see how variously the intellectual faculties may be modified or perverted in cases of hypertrophy of the brain, when the skull does not keep pace with the development of the nervous substance. The troubles of intelligence just enumerated may be prolonged with different degrees of intensity, or they may terminate, more rapidly, in delirium, followed by come and the death of the individual. This is what we have to remark in connection with the intelligence, and the phenomena which it may exhibit. Now for sensibility; what accidents do we sterve in connection with the scusibility?

Is Sensibility Modified in Cases of Cerebral Hypertrophy?

Yes. Observation shows that in most cases the modification of sensibility manifests itself by an habitual headache: this, becom- hypertrophy. In other cases we observe

...

A remarkable case of this kind has been | ing exasperated at certain intervals, and attacking the patient most violently under the form of intermittent cephalalgia, is sometimes a symptom of cerebral hypertrophy. In the first case mentioned by Dance, it was the predominant symptom: we can easily understand how this modification of the sensibility shows itself in headache. The brain is more or less compressed in an osseous case too small to contain it, and must therefore necessarily suffer in proportion to the degree of violence it has to undergo. Several patients experience vertigo, giddiness, &c., as if affected with simple congestion of the brain, and the sensibility in general is modified. In some cases the loss of sensibility is gradual and slow; but in others, after having remained a certain time intact, it is sud-denly abolished: this latter circumstance is remarkable, and we would briefly direct your attention to it. Here is a sudden loss of sensibility produced by a chronic alteration of the brain. How do we explain this? Why should the sensation remain perfect up to a certain moment, and then suddenly disappear? It is not easy to find a reason for this phenomenon, although we have frequently occasion to remark the same thing in other organs, where a chronic disease may exist for a considerable time without producing some one of the principal symptoms which it ought from its nature to develop. Yet at a period when we least expect it, without any change in the march of the disease, or in the condition of the patient, this symptom, so long in abeyance, suddenly makes its appearance.

Lesions of Motility.

The disorders observed in connection with state of idiocy: others had not lost their the faculty of motion are various, and may he specially comprised under the following heads. In many cases we find convulsions, either appearing with little intensity, or coming on at certain intervals. This modification of motility is chiefly seen in children and infants, for it is a general principle, abundantly confirmed by experience, that whenever the nervous centres are troubled in persons of a tender age, this lesion manifests itself in the form of convulsions. In some cases we observe nothing but simple convulsive movements, repeated from time to time : in others the convulsions assume a more grave form, and present themselves with all the characters of epilepsy, terminating in the patient's death: it is a fact now incontestable, that epilepsy may depend on hypertrophy of the brain. We have had occasion to examine a few cases of this kind, and the only lesion which existed,-but it was one that was most evident, impossible to be overlooked,—was an hypertrophy of the hemispheres of the brain. Here then you have examples of excitation of the locomotive powers in connection with cerebral

somens of quite in opposite actors; The different symptoms which depend on the partients are affected with a gradual hypertrophy of the nervous centres, group bandon of motility. This weakness of themselves together in such a manner as to plete and general paralysis. It has also riods. In the first, it presents sets with all been observed that the loss of movement the characteristics of a chronic affection. Then follows the second period. The disaviolent secess of convolutions. In all we case is now acute, it marches rapidly, and have now said, you see confirmed a principle that we laid down in the lecture introductory to the present course. You here found recorded in authors, this succession of see that lesions identical in nature, -for we have treated all along of hypertrophyidentical in its seat,-for we have as yet spoken of the cerebral hemispheres only,may produce not only various, but even opis to arrive at the real cause of disease when the phenomena upon which we have to found our judgment are so diversified and contradictory. Finally, you will observe, that these sources of difficulty, common in a certain respect to all the systems, present themselves more frequently and with more obstinacy, if we may use the term, in the study of diseases of the nervous system.

Respiration, Digestion, and Circulation.

The functions of organic life also present some modifications in cases of hypertrophy of the cerebral hemispheres, but in general we may lay it down as a principle that they are not affected. The respiratory functions are not compromised unless the disease has produced a profound impression on the motility; it then becomes embarrassed and difficult, merely because the mechanical agents which dilate and contract the chest, have lost their power of acting. The digestion is not affected during the course of the disease. As to the circulation, it very rarely presents any modifications worthy of notice; in most cases the pulse beats with its ordinary degree of frequency; in one case only do we remember to have observed a disturbance of this function. The pulse is here more accelerated than natural, but as the case is solitary, it must be regarded as exceptional, and we conclude for the circulation as we have done for the respiration, that it is not implicated amongst the disorders of hypertrophy of the brain. Whenever any excess of frequency is observed, it prohably depends upon some complication of the disease, not on the cerebral lesion itself. In all the cases we have seen, except the one already mentioned, there was complete apyrexia; indeed the pulse has on the contrary a tendency sometimes to full below the natural standard. In one case the number of pulsations was seen so low as forty-five in the minute; but this also must be considered as exceptional, or perhaps it was the natural standard of the pulse in the individual who formed the subject of observation.

Becomes more and more degree a certain march to the disease, and as length perminates in com- distinguish is into two distinct forms or pecase is now acute, it marches rapidly, and the patient succumbs. In almost all the cases which we have observed ourselves or periods exists. The malady commences in a chronic form, and after having pursued its course for a certain length of time, it terminates with symptoms of an acute nature. During

The Chronic Period

we see appear successively all the phonomena that have been already noticed, except delirium; such as various troubles of the intelligence, headache, convulsive motions, and, finally, epilepsy. These different symptoms may manifest themselves smalltaneously in the same patient, or exist singly, in an isolated manner. When this chronic stage has passed through a variable period of time, the acute stage commences, and then we find various symptoms, different forms of disease. In some cases, the predominant symptom is a violent access of convulsions, in the midst of which the patient dies.

The Acute Period.

In other cases, acute hypertrophy of the cerebral bemispheres gives rise to a set of phenomena that are closely allied to cerebral congestion. These may simulate various diseases of the nervous system, and, in particular, cause disturbances very characteristic of acute hydrocephalus. I had occasion to observe at the Maison Royale de Santé a case which fully establishes the truth of this latter observation; the patient was brought into the establishment with delirium, and other signs of inflammation within the cavity of the cranium; he fell rapidly into coma, and was agitated by some convalsive motions; the breathing became embarrassed and stertorous, and the patient died. Before death, we had regarded the case as one of acute hydrocephalus, but on the autopsy what did we find? No trace of meningitis; no effusion whatever of serous fluid into the ventricles. On the coutrary, the brain presented all the characters which we have described as constituting hypertrophy of the nervous substance. This . case was a very remarkable one. The sym, toms had the strongest resemblance to those which ordinarily attend acute hydrocephalus, and might have deceived say physician.

Varieties of Cerebral Hypothrophy. In a disease where the cases that have

been observed are rare, it is useful to draw to pathology. All we can say at preyour attention to particular observations. Thus, we cannot conclude this part of our subject, without noticing the case published by DANCE, in which the patient died as suddenly as if he had been struck by a violent attack of apoplexy, although the disease had not passed beyond its chronic period. The individual, who had laboured for some time ander a violent headache, went to one of the warm-baths in the hospital; he remained about three quarters of an hour in the bath, and on coming out was seized with a fainting fit; this continued for a quarter of an hour, but consciousness never returned. At the expiration of that short period the patient was no more.

Treatment of Cerebral Hypertrophy.

We have now concluded a brief sketch of the history of hypertrophy of the cerebral hemispheres; what shall we say of its treat-It is obvious that we possess no ment? special means of combating the material cause of the disease, the abnormal development of the nervous pulp; our efforts must, therefore, be confined simply to palliate the different symptoms as they present themselves; and the means to be employed for this end are so simple, they follow so naturally from the description we have given of the accidents attending hypertrophy, that we think it superfluous to insist on them at present. We shall, therefore, pass at once to the study of

Partial Hypertrophy of the Brain.

The lesion which now occupies our attention, when confined, as it sometimes is, to a particular region of the brain, may occupy either the deep-scated or the superficial parts. In the deep-seated parts its occurrence is much more rare; however, we have seen examples of this species of hypertrophy. We can affirm with certainty that we have seen cases in which the augmentation of the nervous tissue was confined to the corpora striata; to the corpora ammonis, or the optic thalami; hence we are compelled to admit, on the evidence of our own senses, the existence of partial hypertrophy in the deep-seated portions of the cerebral hemispheres. Now for hypertrophy of the circumference of the brain.

Were I to attempt to lay before you a complete history of partial development of the combral organs, we should find ourselves at cace involved in the grand question of the rel on the relation which exists between the development of certain moral or intellectual faculties, and the corresponding hypertrophy of centain portions of the brain which he regards as the special organs of these faculties or propensities; it is impos-tible for us to enter upon this interesting journal of the Phrenological Society of Paris, No. 1, deback; it belongs rather to physiology than 1835.—En. L.

that as it touches certain parts of pathology, we shall take an opportunity of recurring to it when speaking of mental alienation.

Hypertrophy of the Cerebellum, and its Influence on the Genitals.

We have said that hypertrophy of the nervous pulp may exist in certain portions of the cerebro-spinal axis besides the cerebrum; examples have been seen in the cerebellum. When this part of the nervous centre is hypertrophied, the disease presents itself with the anatomical characters which have been assigned to hypertrophy of the cerebral hemispheres. unnecessary to repeat their description here; it may occur without any appearance of development in the cranium, or the hypertrophy may, in other cases, be attended by a corresponding augmentation in the diameters of the osseous cavity which encloses the cerebellum. Here, again, a highly interesting question presents itself. What influence does this exaggerated nutrition of the cerebellum exercise on the generative organs? Do we find the natural impulse of reproduction elevated with that development of the organ to which some physiologists attribute it? We cannot now enter into an examination of this question, which would be foreign to our purpose; however, we cannot avoid mentioning one or two particulars that seem to throw light on the connection existing between the cerebellum as an organ, and the impulse to reproduction as a function. In the year 1828, M. Felix Voisin paid a visit to the galleys of Toulon, with the express object of determining whether certain predominant faculties are accompanied by certain external signs, the indications of development in certain portions of the brain; he chose, as a test of this doctrine, the reproductive impulse; he examined and measured the heads of 372 individuals confined in the galleys, proposing to select those who had been confined for the crime of rape; the number of these individuals amounted to twenty-two. M. Voisin, without any other indication than that which he drew from an examination of the occipital region, pointed out twenty-two amongst the 372 as the persons condemned for the crime just mentioned. On comparing his list with the returns of the prison, he found that of the twenty-two so selected by him, thirteen had really been confined for rape, or attempt upon female chastity; a great many of the remaining individuals were marked as convicts of bad morals, men whose propensities in a certain way required the strictest watch over them."

Here is a curious coincidence of facts,

and, remark, that if M. Potests the movements and excessive mastufation. where all the individuals confined for the This state of passion continued unabated up crime of supp. this is no wall edjection to the sage of seventeen, when she died sud. against the proposition which he wished to e many men are led to the perious dictates of nature, not to satisfy an a portion of the cerebellum enormously actual animal want or desire, but under the developed, had projected through a deliinfluence of imagination, revenge, and vari- cleacy in the osecous case of the cranium. out other motives of a similar kind.

In some cases of hypertrophy of the torebellum, the organ seems to encroach on the lum may exercise on the gonital organs, mutritions materials of its osseous parietes. These are the principal facts that which it takes to itself to appropriate to its know in connection with the subject now development. Here a portion of the skull before us; but a great deal yet remains to is absent, and the nervous substance forms be done before we can clear up the masteheraia externally, projecting more or rious question of the relation between our less beyond the walls of the cranium. M. faculties and certain portions of the brain LALLEMAND cites an example of hernia of and their development. There is, then, a the cerebellum, although he does not say splendid field open for observation and exspecifically that the nervous substance was periment; you might collect materials for a hypertrophied. Another case, published by curious history, if you were to take all the Dr. BERNET, may be found in the Gazette cerebells you meet with, weigh and mea-Medicale for 1834, No. 42, p. 667. This is sure them accurately, and thus endeavour to a very curious example, and deserves to be ascertain what relation may exist between cited at some length: - The subject of this different conditions of this organ, and the observation was born in the year 1815, and feelings, habits, or propensities of the indiat the time of birth presented no abnormal viduals from whom they were taken, appearance; however, about four weeks; after birth, a small tumour was noticed near the right mastoid process, projecting is the next subject for our examination: it about half an inch beyond the surface of the, may be either general or partial; the latter bone. The tumour remained nearly in the form has not been frequently observed. In same condition for two years, when Mr. one case that we saw, the lesion was con-BENNET, then a student in medicine, at fined to the cervical portion of the chord, tempted to remove it; but the first incision which had acquired so considerable a degree was scarcely practised, when a medullary of bulk as to fill completely the cavity of the substance escaped, and the child sank into vertebral canal. M. OLIVIER affirms, that a state of insensibility. The wound was when the spinal marrow is compressed at closed at once, and the infant recovered after any one point, it acquires an increased voa lapse of six or eight weeks; a second tu- lume immediately above the scat of commour now appeared on the opposite side, pression. This is a curious fact. Does the and both commenced to grow by degrees, until at length they were limited by one large hase; at the age of six years the united tumour was as large as a hen's egg; it was now evident that a portion of the cerebellum projected through an opening in the cranial parietes. Whenever a slight pressure was exercised on the projecting mass, the child immediately lost consciousness, and on recovering, complained as if she had been struck roughly on the head. Up to this period she enjoyed perfect health; the intellectual and other faculties were developed in a regular manner. There was no modification whatever of the sensibility or of motility; however, another phenomenon was observed; at the age of eleven, the first symptoms of venereal passion showed themselves. The girl was seized with a furious desire for the male sex, and all the efforts brain. In the second species we do not find of her mother were unable to prevent her any malformation of the brain, but the spinal from giving herself up to the most unre-chord, enlarged throughout its whole extent, etrained libertinage. When confined to the as LARNNEC has observed, and firm in sub-

dealy, in consequence of having carried a , became many men are led to the heavy weight on the head. The examina-ion of this crims, not from the lun-liciates of nature, not to satisfy an a portion of the cerebellum, enormously Hers, then, we have a manifest proof of the influence which hypertrophy of the cerebel-

These are the principal facts that we

Hypertrophy of the Spinal Marrow

medullary substance in these cases really take on an increased nutrition, and present the phenomena of an artery above the point of ligature?

Hypertrophy of the spinal marrow may be general, and then we observe two sorts or species: in the first, the chord has been found more voluminous in children who are born with various malformations of the body, and deficiency in the brain; there is a want of balance in the development of the cerebrospinal axis, and the chord seems to have assumed to itself the deficiency of instriction in the brain. A case of the first description has been published by M. LANCERNET, in the Archives Generales de Médecine, t. 5. The disease is congenital in these cases, and, as we have remarked, the hypertrophy of the chord is a supplement to the atrophy of the chord, enlarged throughout its whole extent, house, the imperious desire by which she stance, alls the vertebral sanal, and it are twas tormented, declared itself in abandoned by applied against its osseous paristing. The Symptoms of Hypertrophy of the Spinal Marrow

are not, in general, marked with any degree of clearness; on the side of the intellectual faculties nothing has been observed; in one case, where the augmentation of volume was confined to the cervical region, the patient, an infant, was subject to epileptic fits; how-ever, we cannot say if this lesion were the cause of the disease or not, although the former is probably the fact. The absence of any striking symptoms depends perhaps on the circumstance that the chord, in this respect unlike the brain, has sufficient room to increase in its osseous case, without suffering compression, and does not give rise to any trouble of the great functions, unless congestion adds its influence to the operation of the original disease.

NORTH-LONDON HOSPITAL.

CLINICAL LECTURES

ON CASES OF

DISEASE OF THE URINARY ORGANS.

Delivered in the Session of 1836. BY MR. LISTON.

LECTURE II.

Abscess with Stricture .- State of the Bladder.

GENTLEMEN,-The last time I had the pleasure of meeting you here, I endeavoured to explain to you, and to make you understand, the symptoms of stricture of the urethrn, and some of the consequences arising from that disease, and I illustrated these remarks by reference to cases ander treatment: I detailed to you the pathological changes which occur, the alterations that take place in the urethra itself, the manner in which the contraction is formed, the state of the passage, both anteriorly to the stricture and behind it. I explained how abscess formed behind the stricture, coming on sometimes very slowly, and ultimately bursting, with yery great relief to the patient, a con-siderable part of the water, after a few days, heing discharged through the opening, either. in the perineum or in the scrotum,—some-where thereabouts. Occasionally the ab-scess bursts into the rectum, giving rise to very unpleasant symptoms, and complicating the case considerably. This occurrence substance of the kidney itself becomes disin general follows after severe injury of the organized, diminishes in bulk, is softened, perineum. I have seen it happen in two or and, in some cases, almost entirely disapthree patients who had been bruised se-pears, presenting marrely a sort of bag, wenely about the polyic region from hanks formed by the anlargement of its pelvis,

of earth, for hestance, falling upon them, though occasionally abscess forms far back in the canal in consequence of stricback in the canal in consequence of stric-ture, and bursts into the rectum, the greater part of the water being discharged through that channel. I stated to you also the changes that take place as regards the bladder. The balance is such case is lost, or, as the parase is, there is a want of con-sent between the expalling and the retain-ing powers of that visues, which becomes contracted, dissinated resy much in size, and its coats are remarkably thickened, in consequence of the resistance that is offered by the narrowing of the massers. I nointed by the narrowing of the passage. I pointed out to you some specimens in which the muscular coat of the bladder was remarkably thickened, in which, in fact, the parietes resembled more those of the left side of the heart, than those of the bladder in its normal state. The mucous cost undergoes some alteration, and becomes more thick-ened and vascular, the mucous coat, occasionally, being found to protrude between the meshes of the muscular cost. Pouches are thus formed which often attain a very large size. I have in my collection some preparations, which, however, are rather bulky, and not convenient to remove, with several pouches so large as to be capable of containing a small orange. These pouches sometimes attain even a larger size, and seem to resemble almost another bladder. When the opening of the pouch is narrowed, the fluid is first evacuated (whether by the catheter or by the natural efforts) from the bladder itself, after which it comes away from the emptying of those sacs. Those appendages occasionally contain a considerable accumulation of viscid and acrid mucus, and there is no doubt that the abscesses connected with the bladder, which occasionally burst above the pubis, sometimes have their origin in this protrusion of the mucous coat through the muscular marietes.

But the mischief is not confined to the urethra and bladder only, for you find that in cases of stricture, sooner or later, the ure-ters and the kidneys suffer. You find, more especially when the patients have laboured under retention several times, that the ureters are immensely enlarged, and present a very wide caliber, almost resembling the small intestines; their parietes also are thickened; the pelvis of the kidney is enlarged, in consequence of the sort of valvnlar arrangement of the opening from the urster into the bladder being obliterated. If a patient suffers frequently under retention, the ursters and the pelves

with very little secreting substance at all. | panied or not by a discharge, and, perhaps, In cases of retention of arms, you can with some uneasy symptoms about the easily satisfy yourselves, from the symptoms, that the kidneys are more or less affected. When retention has existed for a considerable time, the bladder becomes dis-tended, to a certain extent, and then the secretions are suspended in a great measure but after the bladder is relieved (the pressure probably being taken from the secreting substance of the kidney), the secretion is re-established with great vigour, and the bladder is filled, in the course of an hour or two, to as great an extent as in the first instance. When the kidneys and ureters, more especially the kidneys, are disorganized, from this or from any other cause, the patient may be relieved for a time, the symptoms may be palliated, but his ultimate recovery cannot be expected. He is then in a very precarious condition.

The Treatment of Stricture

demands your closest attention. It is a disease the management of which requires a great deal of skill and derterity. I do not speak of the strictures which are usually met with-slight contractions of the passage, the mere spasmodic contraction, which is attendant upon thickening and irritability of the mucous lining of the canal, accom-

* Mr. Liston exhibited at the commencement of the following lecture a very remarkable and beautiful specimen, illustrative of this pathological change in the bladder; it was obtained from the body of very young patient, under three years of age. This child, very delicate, was somehow seized with retention of urine, labouring under it unrelieved for several days. At last a catheter was used. It was found necessary to continue the introduction of the instrument twice a day for many weeks, the power of expelling the contents of the bladder having been lost. The patient was sent to the Hospital, under the supposition that he laboured under calculus vesicæ. No stone could be detected. All means were employed to palliate the symptoms; but the child, labouring under mesenteric disease. greatly emaciated, at length succumbed. The bladder is capacious; the surface rough and fasciculated. In the posterior fundus is an opening with rounded edges, of the size of a half-crown piece, leading to a cavity formed by a protrusion of the mucous cost, and capable of containing at least 5 or 6 ounces of fluid. The urcters are amazingly enlarged, and thickened in their coats, they resemble the small gut of a child; and the pelves of both kidneys, especially the right, are immensely expanded, the cortical and secreting part of the gland being spread out and attenuated,—Rep. L. parts. That is very easily got rid of by the occasional introduction of a proper instrument. There are before you a great variety of

Instruments used to Dilate and Examine the Urethral Passage.

All sorts of flexible and soft instruments are employed for the management of these diseases; but great objections may be offered to the majority of them. They are apt, unless very cautiously and properly used, to turn up, and bend, in the canal, They come out in a form like a hook, by being pressed against the stricture. or, again, if their points are entangled in the stricture, and efforts are made to press them on by turning and twisting them about, they come out like a cork-screw, well bathed in blood. You can never de-pend upon getting a bougie of this sort through a stricture of the urethra possessing any degree of tightness and clasticity. You are apt to do a great deal of barm with them. If you do insist on employing such tools for ascertaining the existence of a contraction, or for exploring its nature, seat, and extent, they must be used with very great caution indeed. It has been proposed to examine the passage with silver balls of different sizes mounted on wires, but these are scarcely ever employed now. The best instrument for the purpose, I believe, is a metallic bougie, such as I now show you, and you require to have them of different sizes, from below this size to considerably above it. Those, I think, are the best which are made of solid and firm metal, and plated over. You may have them of silver, if you will, but they answer the purpose perfectly well if their surface be smooth. You know exactly where the point of an instrument such as this is, is resting. You can direct it in any way you think proper, by a slight move-ment of the hand. Pressure makes the point obey your will, and you can overcome every difficulty with the greatest facility. But in most cases, in trifling strictures, there is no obstacle. A great deal has been said about the lacung of the urethra entangling and obstructing the passage of the bougie. A very small flexible instrument may be so arrested. The contraction of the muscles may, occasionally, also, prevent, for a little time, the

Introduction of the Instrument but by using an instrument of proper form and size, and by slightly diverting the attention of the patient, these difficulties are, in general, easily got over. I have frequently seen, where there has been slight obstruction from this latter cause, that by

turning the patient's attention in another direction, by diverting him by some trifling observation, or maucuvre, the instrument bas passed in immediately without any difficulty whatever. The muscles surrounding the bulb of the urethra, and the membranons portion, are those muscles which, by irregular and spasmodic action, may offer opposition, but by a little perseverance all these obstacles are to be got over. These muscles are sometimes thrown into powerful, and, in a measure, involuntary ac-tion, in consequence of the instrument coming in contact with the disordered and excitable portion of the lining membrane; the further progress of the bongic is thus opposed and prevented unless unjustifiable pressure is made and continued. Upon the pressure, which should be on all occasions gentle, being relaxed, the bougie is forthwith extruded; this is sometimes followed by the escape of a small quantity of blood, which shows the degree of tenderness of the mucous lining, and congestion of its vessels. The instrument is to be passed, if the patient be in the erect position, with the convex portion towards the abdomen. It is allowed to fall in by its own weight, by a tour-de-maitre, as it is called. You bring the concavity upwards, and then by degrasping, a slight tightness of the passage from the action of the muscular apparatus supporting and surrounding it. That is very specify overcome by gentle perseverance.

Object of the Introduction.

The introduction of an instrument thus gently, affords relief to the patient by diminishing the irritability of the passage, and, if there be any thickening, by promoting the absorption of that thickening. You are aware that the application of mechanical or chemical stimuli, from time to time, to any surface which is naturally irritable, or which has become so from disease, exhausts and diminishes the excitability or the irritability of the part. You introduce the instrument with that view, and allow all the effect of the introduction to pass over before you attempt to introduce it again. You perhaps introduce the instrument when the patient applies to you, allowing four or five or six days to clapse before you attempt it again, and upon the second occasion you will probably get the instrument through the contraction with greater ease; there is, per-haps less irritability, you withdraw it again, and you are enabled to pass one of two or three sizes larger; and in this way you steal a march on the disease, and the patient in a few days is relieved from all his unpleasant symptoms, both as regards the urethra itself, the parts surrounding it, and those parts, also, which have sympathized with it.

Now, in cases of this kind, slight and trifling strictures, as I have called them,there is no use in any other mode of proceeding,-no necessity for having recourse to caustic, which was at one time very extensively used, and used in cases of all kinds -in real and in supposed strictures. People were made to believe, when they applied on account of any uneasiness in this quarter, that they had stricture, and a course of

Caustic Bounies

was then entered upon. A great many people were humbugged in that way, and, as I said before, were even "bungled out of their lives" in the end. DARAN was amongst the first, I believe, who thought of these bougies. The soft bougies are made of wax and resin, or ingredients of that kind, spread upon slips of cloth, and rolled up with a machine; and into this composition Armenian bole, red precipitate, and things of that sort, were wont to be incorporated, in order that the instrument might have a more powerful effect on the contraction of the passage, from whatever cause that contraction arose. DARAN thought there was a sort of wart or caruncle in the passage, and he introduced these escharotic substances, in order that they might act upon, pressing it very gently, you get over every and dry up, or corrode, the warty exobstacle. You may find, perhaps in the crescences. Mr. John Hunter took up membranous portion a little resistance and this subject, and he substituted for the escharotics in use, the nitrate of silver, which, however, he did not use very extensively. He, again, was succeeded by Sir EVERARD HOME, who made a very good job of it. He long enjoyed a great practice in this line, and he made a point of treating almost every stricture in this manner, Mr. HUNTER used his caustic to the anterior and the straighter part of the urethra, by means of such an instrument as I now show you, by means of what was called a "porte caustic,"-a canula, with a wire sliding in it, and a sort of contrivance for containing the caustic at its further end. Sir EVERARD Home, again, fitted the caustic into plaster bongies, such as you here see. Here are a lot of bougies [exhibiting an immense number], for I began to study when the caustic bougies were in great vogue, and with these I provided myself, although I cannot say that I ever used them very frequently. The caustic is inserted into the end of the bougie. Copious directions were given as to how it is to be put in safely, and so on. It seems that the position of the stricture was first ascertained by a soft wax bougie, whether white or black is of little consequence, and then a mark was made on the canstic bougie, corresponding with that on the other; the caustic or "armed" one, as it is denominated, was then slipped down, and held in contact with what opposed it, for a minute or less, according to the determination of the patient or the operator.

This practice has been again revived by lightly; in fact he seems to give it the go-by. Ducamp, Lazamann, and others. What I here, again, show you, are some of the instruments which have been invented lately dred and two times. In another year it was, for the purpose. They consist of a straight applied one hundred and forty-eight times, or a bent canula, with porte caustics, which are to be passed through the stricture, so that the caustic may be applied to one side or the other. There are little cavities in which part is pushed through it. The caustic is thus applied to whatever side of the canal is supposed to be most diseased. Here are others, for taking an impression of the part previously. This is just a return to the oldfashioned absurdity of measuring to ascertain the site of the stricture, getting a mould of it, and then pretending to burn it out,—a capital way of picking people's pockets you may depend upon it. This caustic did, undoubtedly, sometimes do good, because when nitrate of silver is applied it will diminish the irritability of the part, and sometimes the patients passed their water easier, and the bougie slipped more readily through the stricture afterwards. The remedy was all very well when employed in this way, lightly and seldom, so as to diminish the irritability of the canel; but when it was applied with a view to drive a mine through the part, to destroy the living stricture, why then it did a great deal of harm. I don't mean to read all the books to you which I have here, but I have brought them in order to let you see the sort of practice that was pursued when I began to study. Here is

One of Sir Everard Home's Caustic Bounie Cases.

for an example, and if no great good was done to the patient by this practice, depend upon it it was very advantageous to the practitioner. The case is one of many of which the book is made up. The patient, a gentleman, had had a clap when sixteen years of age; the inflammation was very severe, and lasted nine or ten months; then a gleet came on; he used astringent injections; the discharge stopped, and the urine was voided with difficulty. The gentleman then applied to Sir EVERARD HOME, who examined the urethra with a bougle, and applied the caustic. Up to a certain time the caustic was applied fifty-one times; then, causic was applied inty-one times; then, that have recommended and ten times; then the patient went into the country, and which is called a "lanewas applied one hundred and ten times; then the patient went into the country, and which can be made to protrude at its point, had it applied thirty-eight times. This is lit is a very dangerous sort of tool. Indeed related in a book which Sir Benjamin it do not know who would choose to have Broder recommends as a very valuable and this introduced into his urether. It must be excellent work! I do not know whether a highly dangerous proceeding in the hands

a pretty source of revenue at a guinea a time, I should think. From November to the end of June forty times. In all four hundred and eighty-nine times in this one the caustic is put. One part of the apparatuse! But there are some other, cases tus is carried down to the obstacle, and that equally good, if not better. This patient continued free for some time from any relapse, but he was still under the necessity of passing a bougie daily into the urethra, and leaving it in the canal for half an hour at a time, to keep the canal in a state of freedom. Now who will be bold enough to call this a cure? Why, after all the four hundred and eighty-nine applications of caustic, he was under the necessity of using a bougie from day to day! A pretty account this, from the surgeon's own mouth, of the success of the practice which he recom-mends. Yet for years such proceedings were lauded, and nothing would go down but treatment by caustic bougies.

But this has given way to another piece of nonsense, I can call it nothing else,-the cutting of the strictures from within, the using of

Cutting Catheters,

which are not a whit better, or more safe, than the caustic, depend upon it. This practice has been recommended by various surgeons, and I now put before you the various apparatus of those different people. Here, in the first place, is that of AMUSSAT: it is composed of a straight silver bougie, in two parts, joined by a screw. This is passed through the stricture first. (You know very well, that when we can get an instrument like this through the stricture, we consider the cure to be all but complete.) Then the canula, with cutting edges at its extremity, is pushed over, the penis being grasped and pulled forwards, so as to put the urethral canal apon the stretch. The instrument is constructed to cut the internal parts, in the same; way as a stricture in the rectum has sometimes been cut when it is unyielding. It is no bad notion, but still it may prove injurious, and it is a practice which is not required. This instrument I had from Amussar himself, and is one which I saw him use. Here, again, is another contrihe recommends the practice now or not. He used at one time to talk in commend-tion of it, if I mistake not, but on his own is small catheter is to be passed, with the wire book he passes over the subject rather in it; the catheter is then withdrawn, she

wire being left; the wire is then carried whistle, scooping it out as you would the through the centre of this cutting instru-ieve of a poisso. It might be called the ment, and is intended to serve as a guide to it. It would be all very well if you had any means of fixing the farther and of this wire. and made a fuss about. Some of you may ment, and is intended to serve as a guide to If you could but put your fingers in any way into the bladder, and lay hold of the wire, then the conductor would be perfect, and you could push the double lancet down, and divide the parts safely enough. There are other machines of the same fashion; here is one of LALLEMAND's, and I think it is safer than most of the others. A little lancet is protruded, and the stricture is cut, either by pushing the instrument forward, or in withdrawing it,—all very pretty things to look at, and very useful to the instrument-makers, who of course approve of them; but not so to the patient, as he finds, in the end, by sad experience.

Now in slight cases of stricture, none of these plans by caustic or by cutting can by any possibility be required; and in had cases no good can result from them. If you could succeed in boring a hole with caustic through a contraction,-and you might do so, were you to use the kali purum, the infernal stone, as it has been called, and which has even been recommended by some innovators and schemers, you would not benefit the patient,-you would certainly leave the patient after great suffering, in a worse state than you found him. Great and imminent dangers arise from the use of any caustic. There is risk of hemorrhage, of rigors, of false passages, and I cannot tell you what else.

But even if you could succeed in passing through the obstacle, you would leave a large internal sore behind, and what are you to expect from the cicatrization of that? Why a worse contraction than existed before. The same observation might be applied to the employment of the cutting in-struments. No good can result in a very tight stricture, by dabbling at the near end or commencement of the contraction, with any of them. You would no doubt make a breach of surface in the membrane lining the passage, but you would not succeed in getting through such strictures, as you see in these specimens or drawings, - such as those which patients in the hospital labour under-strictures involving an inch or more of the trethra. You produce, perhaps, a solution of continuity in the inner surface of the cand, and you must have a cicatrization and contraction, in consequence, in that pagt. Moreover, your patient will very soon labour under a worse stricture, one more tight, confirmed, and unyielding, than you first found him with. I am astonished that some of the clever people who have turned

take the hint and publish a book on the subject. The name is at your service, and you might get a good deal by it.

Now these bougies for burning and cutting you are certainly not warranted in employing in ordinary cases of stricture, and in cases of tight stricture, and all cases of stricture involving a considerable nortion of the canal, they cannot possibly he applied with any advantage whatever. What are you to do then? I would have you proceed in the way you have seen cases managed in this hospital. Some of them have, I am sure, been turned out cured after a very short process. I would have you attempt to get an instrument through the contraction, and if you succeed in your object, however small the instrument may be, you will ultimately have but little difficulty in overcoming the disease. I am talking of bad strictures now, such as I showed you preparations of the other day; such contractions as you see in some of the preparations in muscums in which punctures above the pubes, and punctures in different parts of the bladder, have been resorted to. I have none such in my collection. You are, however, to try to pass an instrument, and if you succeed, as I have said, in getting one through, however small the instrument may be, the cure is completely within your grasu. A great deal of care and caution is necessary in the introduction of instruments in such cases. Sometimes you may be foiled in passing an instrument in the first instance, but if any water come through at all, if the bladder be capable of relieving itself in any way, you are not to be disappointed; at least, if you have gone about it gently, in general no had effect can result. You will attempt the introduction at another time, and perhaps succeed at last in getting one through, and there you would retain it.

Proper Catheters .- Mode of Use.

The instruments which I should recommend to you in tight and bad stricture, are catheters, such as I now hold in my band, pretty firm and well tempered, which will not bend and yield readily. You may use them of any curve you please, the less bent the better. These are good old-fashioned catheters with large metal rings, by which you have quite a sufficient hold. They are far to be preferred to the new-fangled tools with wooden handles, well furrowed, in using which you lose the advantage of that delicacy of touch by which alone you can guide the their attention to this subject should not point of the instrument certainly and safely have thought of employing a "punch," as to its destination. I must say I do not fancy it is called, on the end of the catheter, and any instrument whatever with a rough taking a bit out of the canal, as clean as a handle, and far less sounds, staffs, and ca-

theters, which are intended to be passed into deep hidden parts, and the sale conduct of difficulty in passing a Catheter which depends upon the malious of the than when the bladder is capable of reliev fingers, regulated by the feelings commu- ing itself, because then there is a straining and perhaps that there is a second contract [Air. Hay, one of the very many diligent put in great safety pass forward the eatheter, because you are uncertain whether the resistance is offered by the grasping of the first stricture, or whether it is owing to the considerable time before he came in, and impression, that the patient had not for a first stricture, or whether it is owing to the considerable time passed any water at all opposition of the second one. You retain the catheter for a little while. If you are by perseverance the catheter was at last got any stricture, and it is an chieft to get the cat list to blockler. anxious, and it is an object to get the ca- into the bladder. I have before me the notes theter into the bladder at that time, you may of a somewhat similar case, written by the withdraw the first instrument, and then try patient himself, in which he says, that in one of half the size. That will not be held the latter end of 1826 he had a stricture. by the first stricture, and you will then probably get it readily through the second, and
loige it in the bladder. But you will recollect that there is a dilatation always behind
the stricture, and you must be exceedingly
cautious in passing it through the prostatic
portion of the urethra. The ducts are alportion of the urethra. The ducts are alportion of the urethra wise and if you do not
according to the prostatic processory. intention of enabling you to ascertain exactly what direction it is taking. You withdraw the catheter a little, and pass it on again, if there be a resistance, until you passing of the water of course affords evidence that all is right.

Now, as I said before, you may find it impossible to pass the instrument in the first instance, but you are to try it again and again, and at last you ought to succeed. so ill on his voyage, that for the last nineurethra, although it may be in a very shabby where water was passing away, been very serious local mischief would have taken much afraid, lest I should be called upon to place, and that other bad consequences did cut into the urethra behind the stricture. not occur is astonishing. A swelling formed You may be called upon to do so in cases behind the acrotum, and burst; an abscess where you have been foiled in passing the had formed in the perineum, and he was instrument through the urethra. But I relieved. Upon his arrival in this country think that

nicated through their nerves. In looking of the bladder. The urethra behind is conover the stores of instrument makers, one siderably distended and colarged, and there would be led to suppose that the different is less difficulty in finding the canal behind cutting and boring machines had been continuous the stricture, than there is when there is trived by some very nervous and shaky retention of urine. I should say, that some gentleman who was obliged to hold on like times, even where no water has passed at grim death, lest his finger and instrument all, for a long period, through the natural in his excessive agitation should part company. You must begin with a small one, theter through. I have had to treat some You will pass it down, and probably get it very had cases at one time and another. I through the first contraction, by which you mentioned to you a case the other day, that willfind it firmly embraced. You should pass your finger into the rectum as a guide, not with a view of minutes. From the external opening of the changing the position of the point of the in- urethra to the entrance into the bladder, strument; that you cannot do; but with the the parts, he says, were swollen enormously. He was told that he laboured under disease of the prostate. Indeed, it is astonishing how many practitioners fall into the blunder of supposing that young men are laboursucceed in lodging it in the cavity. The ingunder that affection, for it is only in old age that the sort of hypertrophy, or enlargement of the prostate, takes place. There is no disease of the prostate gland in young men; the obstacle is generally situated far-ther forward. He was sent home, and was If any water comes away at all through the teen days in August, he states that he could not make a single drop of water, and superway,—by mere drops,—you ought to succeed in getting the instrument into the bladder. I have, in two or three cases, neys must have been suspended, otherwise he applied to medical men in his neighbour-

hood, but they could not pass any bougie, and for two months before he came to me, not a single drop of water had passed through the urethra. He could not retain Ms water; it was running from him at all times, and occasionally violent spasms came on, of the most excruciating kind; there was violent straining of the bladder, and of the muscles that are concerned in emptying it. In that case a catheter was got through the firstestricture with no very great difficulty. I could not succeed in passing it to the bladder at first, but I assured him that every thing would go on well, and begged of him to retain it in half an hour; I returned and withdrew it, and at the same time took the liberty of passing one, a little less in size, through the second contraction, into the bladder. This catheter was retained for forty-eight hours. That was taken out, and one of about double the size was introduced. The day after, a full-sized catheter was passed into the bladder without difficulty. It was withdrawn, and he was allowed to rest. In two days the catheter was reintroduced readily. Since then it has been passed four or five times, with an interval of five or six days, and having regained his health and strength, he now walks about Delivered in his Course on Hygeine, at the Lecture and amuses himself, having completely recovered all the functions of the parts; the openings have nearly healed up, and he will soon be perfectly well. As regards the fistulous tracts and openings in the perincum and scrotum, the removal of their cause (the obstruction of the passage in the great majority of cases), suffices for their cure-they gradually cease to give exit to urine; it passes slowly, then in drops, as the stream through the natural passage improves, and, finally, both that and the purplent secretion cease entirely; the hardness gradually disappears. It may be now and then necessary to dilate the openings a little, to foment, and enjoin rest, if, after the introduction of a bougle, pain or swelling should supervene. In some few cases, when perhaps the whole of the urine has found an exit for months through a false passage, and when that does not close after the urethra is put into good order, you may be called upon to employ means to promote and hasten the closure of the sinus. In those cases, in which a communication has been formed with the bowel, also, further proceedings are called for than a "course of bougies." You may have to retain a catheter for some time, though, occasionally, ulceration is proleved or kept up by a foreign body in the rathra. The means most effectual, and by nucle in to be depended upon than real or supposed caustics, is the application of a reated wire, and that is almost the only s I apprehend, the actual cautery can be sent conception of the essential principles satisfiably employed. We can when some he taught? His words are on some of our

would have recourse to its use, attain our object more specific and effectually by less painful and much less appalling methods. Here, however, the extent of the easterization on be more certainly regulated, and the contraction which follows is more complete than that which follows any potential cautery. If a repetition of the application is called for, a sufficient interval most be allowed to elapse betwixt the operations. The contraction must be allowed to go as far as it will do after one touch of the wire, before it is repeated. As yet we have had no trouble with those cases of fistula in perineo which you have seen treated in this hospital, and these have not been few since it has been opened for the reception of pa-

LECTURE

ON THE

HISTORY OF HYGEINE.

Room, 8, Grafton Street, Fituroy Square,

By WILLIAM FARR, Esq.

Travels of Hippocrates .- Philosophy of Life and Death .- Defects in the Ancient Medical Classics .- Climate of Greece .- Epidemics. — Cases reported by Hippocrates. — Criscs of Diseases; real Signification of this Ductrine .- Diseases have a determined Duration .- Diseases terminate naturally in Recovery .- Philosophy of Diet .- Relation between Diet and Exercise. - First Signs of Excess in Food .- Adaptation of Diet to the Seasons .- Influence of Climate on Man. physiological and pathological.-Changer of Climate advantageous. - Influence of Social Institutions .- Proofs that the Hygeinic Department of Medicine, cultivated with so much care by Hippocrates, may exercise more Influence on the Health of Mankind than Drugs.

GENTLEMEN, - The architecture of the Greeks, their poetry, history, and philosophy, have been understood in this country, and are regarded with reverence by their equal and natural judges; but how do we regard the medicine of the Greeks? Are we as well acquainted with the works of Hippocrates as the artist is with the creations of Grecian sculpture? We know his name; the cyclopedists trace many fantastic ase in surgery,-those false passages about doctrines to his works; a quotation now and he male or female organs, - in which, so far then crosses our path; but what is our prelips, but is the philosophical physician's and health and death, are but states of matching the death and physic therefore in our hunge; Among the that the birth of one hody is the death another; that the composition of one had a member of the Council of the College of Surgeons, in his evidence before Parliament, and,—"I believe that neither Hippocrates, Gelen, nor Caissa, would obtain our diploma: they would all be turned back in five minutes by either the College of Surgeons in the same than a community of the same thing—combination and decomposition of the same three same that the same three same thre geons or the Apothecaries' Company." the same thing,—combination and decom-Dunces, you know, are sometimes kept up position, changes of form. Men their that half an hour in Lincoln's lan-fields; but what springs from invisibility into light is the insufficiency of Hippocrates would be created, that what passes from light to darkapparent in five minutes. He would in-ness, perishes; but we must believe the evi-evitably be "turned back." This was spoken dence of our own eyes rather than uneviby a gentleman of "infinite jest;" yet it is denced opinions. All things buman underprobably soher truth, and shows how great go metamorphoses, increase and decline to men may be treated with contempt where their maximum and minimum, as the sun their greatness is forgotten. A good English translation of the works of Hippocrates. a better knowledge of Greece, and a higher tone of thinking, will, no doubt, in the end necessity. place the medicine of the Greeks in the same advantageous position as their other arts.

In inviting you to examine with me the doctrines of Hippocrates, in whose mind the hygeine of civilization first assumed a consistent form, it is not from any desire to enforce them by a superstitious regard to antiquity or authority; but in the hope of being able, after familiarizing our minds with great and accurate thoughts, to apply with greater success to the investigation of

Nature.

HIPPOCRATES, born in Cos, a small island on the luxuriant coast of Asia Minor, was Hippocratic writings, -particularly on anathe second of that name, and inherited all the accumulated wisdom of an ancient family of the Asclepiadæ. His career commenced 460 years before the birth of JESUS CHRIST. He travelled through several states of Greece, spending his time chiefly in Athens, Thessaly, Thrace, and the island of Thasos; he visited many of the neighbouring people, and after attaining great glory in that country and among his disciples, retired to Cos, to devote himself to his writings. In this island, or at Lurissa, he died, aged eighty-three years. It was the time of the Peloponnesian war,-the age of Pk-RICLES Buil SOCRATES.

HIPPOCRATES was not the author of all the works now printed under his name; he wrote but few himself; others were committed to writing and extended by his followers, or they were the productions of his family. I proceed to develop his views of hygeine from the more authentic documents, as they form a more enlarged system of health than has ever been conceived by any other man. In general I have followed the admirable Coray in the translations, but if I have in any cases mistaken the sense, I shall thank any one who may be a good Hellenist to put me right.

HIPPOCRATES, as the basis of his philosophy, lays down that life and organization, of the temperate zone, surrounded by the

what springs from invisibility into light is and moon, as light and darkness. In its changes, everything, great or small, fulfils its fate, willingly or unwillingly, by divine

In examining the doctrines of Hirro-CRATES, we must never forget-although the anticipations of his genius sometimes tempt us to forget-that he was the first who devoted himself exclusively to the study of physiology, and to the cultivation of medicine. The nature of man, his organization, his relation to the external world, and the causes and remedies of his multitudinous diseases, when first opened to investigation, revealed questions enough to overwhelm the mind with confusion. Should we, then, he astonished to find errors in the tomy, and on subjects which the prejudices of the Greeks and the want of instruments prevented him from examining? His discriminating genius is discoverable in the direction of his mind to objects within reach, and of most pressing interest to humanity; the imperfection and uncertainty of his principles resulted from the want of instruments for measuring phenomena. He had no barometer, no thermometer, no hygrometer, so that all his observations on tourperature and moisture are indeterminate; be did not employ enumeration to measure the duration of life and disease, the proportion of sickness, the various forms of discase, and the deaths in all ages and under all circumstances; yet in a great many in-stances he has predicted what calculation will prove to be correct; he has measured the evil in his mind, and foretold the remedy.

Every form of malady and death may happen to men of all races, of all ages, and at all seasons, - but the relative proportion occurring in these various circumstances is very different. Greece is situated between the 36° and 40° of N. latitude; it is traversed by the Isothermal line, 181", centigrade; more than nine mouths in the year the temperature is higher than that of spring in England. Placed on the tropical border Mediterranean, bathed by the hot winds of tions were recorded, it was easy to accer-Africa extrated over the sea, chilled by talk the periodical changes and the course the north-east winds of the continent, or of a disease. He did not reckon by days of gefreshed by the life-giving west, Greece, the month, as is done in the present day, from its multitudinous shores to its lofty but by days of the diverse, dating from the mountains, some of which rise 7000 feet, onset; he does not say on the 3rd, the 6th, presents all the fruits of the tropics, intermingled with the corn and flocks of England. Many districts have no direct outlet place; or the malady terminated. One of to the sea, and the shores are marshy, which, with the heat of autumn, produces the fevers of the tropics. In January, the pulmonary affections of England prevail. Out of 15,191 diseases occurring among the English troops in the Ionian islands (1816-1821), 5721 were common, remittent, or intermittent fevers; and it was observed that while the fevers of the troops were remittent, those of the natives were intermittent. The same class of diseases, and the same difference, were observed by the French in the Morca, during their last expedition.

In the books of Epidemics (ext upon 8 nuos the people) HIPPOCRATES attempted, and in part realized, the great undertaking of presenting all the diseases of a people in connection with the natural phenomena of the seasons. The constitutions of the years are determined; the winds, the heat and cold. the moisture and dryness, and the order of their succession, then the reigning morbid constitution, the mortality and the duration of diseases, the ages, sexes, and occupations most afflicted; while illustrative individual

cases follow.

24

The term epidemic now designates one widely prevailing form of malady. Epidemic, in its present sense, is the reigning disease of Hippocrates, to which he did not confine his attention, but took into consideration, and described, all the contemporaneous types of sickness. In the late dethat statistical writers in England. Gerselves almost exclusively to reporting the deaths from cholers, and sometimes the cases. Now the total deaths or cases out of the living at each age, and the deaths from the epidemic, compared with the deaths from other causes, were the most essential and interesting elements of the problem which they sought to solve,-elements which they overlooked, and which HIPPOCRATES especially regarded.

In reporting cases, his choice was influenced by the character of the disease they were intended to represent. He neither re-ported merely fatal cases, as is too often done by the French pathologists, nor did he confine his relations to cures—the rock on which we often split in England. Boyce somewhere censures Hippochates for narrating so many unfavourable cases, but this scientific candour was an element of the on these than on other days; and this may great observer's immortality.

&c., of the month, but on the 3rd, the 8th, &c., of the disease, such a change took the shortest cases will make this clear :-

Eighth Patient.—A young man, who slept in the market-place of Liars (Athens), was seized with fever from fatigue, labour, and unusual walking. 1st day. Stools bilious, thin, abundant; urine thin, dark-coloured; no sleep; thirst. 2nd day. General exacerhation; purging frequent, excessive; no sleep. The mind agitated; perspired a little. 3rd day. Malaise; thirst; loathing; great restlessness; despair; disturbance of mind. The extremities livid and cold. Precordia swollen, softish. 4th day. Had not slept; growing worse. 7th day. Died. Aged 20.

By forming a table of such cases-perhaps without doing this-it would be easy to perceive whether the crises occurred on any particular day, or in any definite time. The crises of some fevers, it is said, happened on the fifth or sixth day; in others, no crisis took place before the 20th, 40th, or 80th day; some never came to a crisis. Fevers, in which life is destroyed or saved, terminated in the same number of days. Relative to the crisis, some days are called " remarkable" (περισσός), which was translated into Latin by imper (odd, unequal); but means, according to good Hellenists, unequalled, superior. The chief critical days were the 4th, 7th, 11th, 14th, 17th, 20th.

Diseases were divided into three stages. In the first the crude morbid elements existed, in the second the morbid product was scriptions of epidemic cholera, you will find formed, in the third it was expelled, and this coincided with the termination of the mormany, and France, have restricted them- bid revolution. The crisis was synonymous with termination, whether by recovery or death; but it was sometimes applied to a single symptom.

HIPPOCRATES appears to have been misunderstood with regard to the doctrine of critical days; for instance, Crisus misstates and combats that doctrine on erroneous grounds. Some appear to think that HIPPOCRATES imagined that diseases came to their crisis, or, in other words, termi-nated, only on the critical days; how incorrectly, the following forty-one cases, recorded in the first and third books of " Epidemics," will make manifest.

Here the crises are distributed very unequally, because they are few, and they are not confined to the critical days. It could, consequently, only be meant to affirm that, on the average, fevers ended more frequently be more obvious in the intermittent diseases From the manner in which his observa- of the Mediterranean than in this country.

Taxia 1.—Crism of 41 Union of Discon, younged by Harrocantas in the first and third Books of "Apidemies;" showing the days on or before which they terminated by either Duth or Recovery.

Day.	Crises.	Day.	Crises.

7	3	24 27 34	2
10	1 1	40	3
11		80	3
Î4	3 2	120	2

But there is another sense in which the Hippocratic doctrine may be understood. He may have divided acute diseases into periods, in order to predicate when the ma-jority of crises occurred, although the oh servations were not numerous. And this sense is supported in the book of " Criscs," where it is said that the mildest fevers terminate on or before (wpouder) the 4th day; the most deadly destroy on or before the 4th day. So the first access (foodes) ends. The second extends to the 7th, the 3rd to the 11th, &c. I therefore think we may admit that acute diseases were divided into weekly periods, and that these were subdivided into intervals of four and three days, as half a week could not be expressed in entire days (Shais quipais). The foregoing forty-one cases, thus arranged, would justify us in saying concisely, that the crises took place on or before the 7th day, and that the diseases in question were judged by the 20th, as ten cases ended in the second period (προσθεσιε), and only thirteen out of fortyone remained at the end of the third week.

Table 2.—Weekly and Half-weekly Crises of the preceding 41 Cases; 24 of which were by Death, 17 by Recovery.

3	14-17 17-21	3 }	7
4	\$21-24 24-27	2	3
5	34	1	2

The eight remaining cares terminated on or before the 40th, 80th, or 130th day.

Whatever the Hippocratic doctrine may be, it is certain that is this country, in France, and in Germany, few disease terribinate des justicular days, or at one period; but I shall be able to show you, that the termination or crisis of several, and probably of every disease, takes place according to a determined law, which may be at any time deduced, when the observations are sufficiently exact and numerous. Dr. LATHAM has reported 297 cases of typius fever, to refute the Hippocratic motion of critical periods,—to show that the crisis of that disease is irregular, and subject to no law. When properly arranged, they prove exactly the reverse grant of the critical periods.—The state of the critical periods.—The state of the critical periods.—The provement of the critical periods.—The critical periods of the critical periods.—The provement of the critical periods.—The provement of the critical periods.—The provement of the critical periods of the critical periods.—The provement of the critical periods of the critical periods.—The provement of the critical periods of the critical periods of the critical periods.—The provement of the critical periods of the critical periods of the critical periods.—The provement of the critical periods of t

TABLE 3.—Crises of 17 per Pener reported by Dr. LATEAN; we have not state how many digd or recovered.

Day	Crises			Day	Crises.
5	2	24	10	42	4
6	3	25	6	43	2 3
8	3	26	4	44	3
9	2 3 3 6	27	.7	45	1
19	3	28	8	46	4
11	12	29	4	47	1
12	13	30	111	48	1
13	12	31	11	49	8
14	8	32	6	50	1
15	9	33	8 1	51	1
16	14	34	6	53	2
17	12	35	5	55	2

21	8	39	5	60	1
22		40	8	62	1
23	7 9	41	3	65	1
		<u>'</u>		<u> </u>	

In looking over this table, it may be supposed that the 11th, 12th, 13th, 18th, 24th, 30th, 31st, and 49th, were critical days, as the great number of cases terminated on those days; but this irregularity is owing to the small number of facts being divided into a great many sections. If the cases were more numerous they would terminate regularly, as in Table 4; where longer spaces of time are employed:—

jority of patients recover from disease; that the unifority of fevers, inflammations, and other severe malsdies, seldom destroy more than a fraction of those attacked, when left to pursue their unobstructed course. In Corfu, where the annual denths were 27.4 per 1000, only 23 died out of 1000 attacks from disease of all kinds, sufficiently severe to send the soldier to the hospital. I never saw this calculation made for England; but I think it furnishes an approximation to the general truth. The patients were treated, and the deaths were no doubt considerably diminished by medicine; but without any diminished by medicine; but without any treatment. If 42 out of 43 had not survived, the great manufactual have recovered. The natures of diseases are the best physicians (Neisser poores myos): wherefore Ilprocurates scrupiously abserved their natural evolution, all the things, and the increased excretions where manufactured excretions where male where molecular accidents on the natural threatened the extinction of life; a opposed them, by endea-toning to induce the natural crises—to vonring to induce the natural crises,-to bring cases, precipitated by something into a fatal route, back to the natural course of those ending in recovery.

The Hippocratic doctrines of diet present a philosophical outline of that department of hygeine. A writer on the diet of man, it is observed, should be acquainted with the nature of the whole body, its organs, and the subordination of its powers; should be acquainted with the qualities of all food and drink in the natural and in the prepared states; should know the way to dilute strong things, and to make the weak stronger, by art, as occasion may arise. Nor is this enough; for a man cannot be healthy unless he works as well as eats. Food and lahour are opposite forces, which, when in accord one with the other, constitute health; for health is perfect when the clements of the body exist in due quantity, power, and composition (crasis). Labour consumes the principles supplied by food; therefore it behaves us to determine the force of labour, both natural and violent,such as gives, and such as takes away flesh; also the relation of labour to the quantity of food, to the constitution of men, to the size and age of the body; to the seasons, the winds, the site of the country in which they live; to the prevalent type and to all the causes of disease. He who could discover an exact measure of the relation between labour and food, would detect the secret of haman health. But this is impossible; they f dannet be made symmetrical; yet, as when one is a little defective, the other force runs into excess, there are means of detecting the excess of either, before the slowly-accumulating disease bursts into a flame.

In the application of bygeine it is of the utmost importance to be able to distinguish

HIPFOCRATES was well aware that the ma- is the first abstractions from health: these are rity of patients recover from disease; that leminously treated, probably from observate unifority of fevers, inflammations, and tion in the gymnasta. The first signs of disease from repletion are, I. A stuffing in the nose after dinner, with a secretion of mucus and saliva on the following morning; heaviness of the eyes, paleness, and loss of appetite. 2. Long and agreeable sleep, sleep in the day, followed subsequently by troubled dreams. 3. Lassitude; pains of the whole body, or of parts of the body Heaviness and headache; the eyelids dropping after dinner, and convulsed in sleep heat, and sometimes costiveness. 5. Flatulence, voiding the aliment soon after eating, which seems to yield relief, but is soon followed by heat, and diarrhoea, or dysentery. 6. Crude, but not acid eructations; scanty stools compared with the food, yet really copious, with no internal pain. 7. Pallor and acid cructations shortly after eating. 8. Acid eractations on the following day. 9. Profuse perspiration in the first sleep, suffication, heat, vomiting. 10. Liquid steels, without pain; wasting. 11. The food passing away undigested, but not putrid; wasting. 12. Watery putrid stools, without other inconvenience. 13. A dry, and in process of time, a bitter mouth, confined bowels, hard dry stools, ending in stercoraceons vomiting. - Exercise is excessive where headaches and shivering come on after the morning walks. Some shiver in the gymnasium, from the time they strip till they begin their exercise, and on cooling, their teeth chatter; they are sleepy, and when awoke they feel giddy; their eyes are heavy; malignant fever supervenes. Labour has exceeded food.

The regulations respecting seasons hold still in Greece, and require little modification in England. In WINTER eat once a day; lunch very moderately. The food should be dry, rich, heating. Do not go through a gymnastic training in winter; the trees which have not wintered hear no fruit, nor are they healthy. Warm the body with labour, to promote perspiration. Day is short, night long, and this teaches us that labour should be neither long nor excessive. -String. When Arcturus arises, when the south winds blow, and the swallow comes, food, drink, and labour, should be more varied, milder, and lighter. As about the equinox (March) the days are lengthened, the nights shortened, the season is warm and dry, diet should be nutritious and rich. The trees, devoid of reason, provide themselves in this season with increase and shadow, against summer; so should rational man preparc a healthy accession of flesh. In Sua-MER the food should be softer and more sparing; drinks mild and diluted; luncheon moderate, and the siesta brief; excess in meat or drinks as slight as possible. Sexual intercourse should not be indulted. Tenid bathing may be used. Avoid the sun, and

the cold morning and evening rapours, diet, and temperature, are alone perfectly crimining from threets, lakes, and shows. At such: In the mild, equable climate of Asia, the hummer solidice take no dry, hot, rich every thing grew in greater size and beauty things. Average—From the equitox (September 1). tember) guard against extremes of heat and cold by thick clothing; walk out on warm days; use tepid ablutions; warm and dry food.

Many of the aphorisms are useful general guides in diet, such as, " Beware of sudden changes in living:" "The hungry should not work:" " Those who feed fast and suddealy, may be suddenly reduced:" " Those who waste slowly, are restored slowly: "The more that unsound bodies are fed, the more they are injured:" "There is more danger in living on a weak and strict, than on a rather full, diet:" " A high state of

gymnastic training is dangerous.

The atmospheric origin of some diseases was recognised by HIPPOCRATES: the nature of man cannot always resist the power of the universe; and certain conditions, constitutions, and climates, impress a peculiar form, not only on disease, but on the entire organization and character of the human family. These are treated of in the book of "Winds, Waters, and Places," presenting a physiological view of the principal races of men observed by him in Asia and Europe, developing their innate energies, such as they were fashioned by the earth, and subject to the diseases induced by the external elements. This book is a perfect model of physiological delineation. Phidias, or Zeuxis, never sculptured the human figure more divinely, or painted with more expression, than HIPPOCRATES has here traced the Asiatic and European character.

The influence of the earth on its human inhabitants, is expressed somehow in this manner:-You will almost always find the forms of men and the nature of a place, corresponding; for where the soil is rich, and soft, and wet, and of uniform temperature, the people are gross, lymphatic, of relaxed joints, intolerant of toil, and cowards; indolent and sleepy; they are neither keen nor subtle, but dull in the arts. On the contrary, where a region is bare, rough, un-sheltered by nature, oppressed by the cold of winter, and burnt by the summer's sun, the men will be found spare, robust, of well-expressed form, vigorous, and swarthy; they will be capable of toil, and wakeful; their manners will be pertinacious and contumacious; they will be easily roused to anger; fiercer than mild; exceedingly acute and dexterous in the arts; expert in war. For whatever springs from the earth, savours and participates of its nature.

To great changes in the weather, and sudden irregular successions of heat and cold, moisture and dryness, HIPPOCRATES attributed great power; he considered them the most common causes of disease, and ature at which corn would grow to that at often states that slow alterations of habit, which the grape, or orange, or olive, would

benign and refined; at the same time the inhabitants were rendered timid, effeminate, indolent, and unwarilite. The amo-sphere around them key stanguil, and was insensibly changed; hears the soul was never shaken, the body never tossed about, and tried by changeful vicisaltade, which probably exasperates passion, and excites heat, and intellect more than repose. For changes always rouse the mind of man, and

permit it not to rest.

When the organization is thrown into motion by the external forces of nature, and then suddenly abandoned to its own resources, an effort of self-action is made, which gives and concentrates independent power; and thus Nature hears her children, as on eagles' wings, into the higher regions of exertion, and educates them till they can triumph over their element, and ride upon its storms. Excitement of the mind, and of animal heat, which have many analogies with each other, is equally favoured by changes of temperature. We may conceive that in a cold atmosphere a great supply of internal heat is demanded, and when the atmosphere becomes warm, the supply will be superabundant; and this principle of reaction not only applies to calorification, but to the muscular, the nervous, and all other organic functions. In the political changes, the stormy years, of the Peloponuesian war, Greece produced many of its immortal works. Man is ever seeking an equilibrium, but that is repose and death. When the equilibrium is most disturbed, he is most active. Variations in the intensity of external agents serve not only to augment the sum of power, but they temper the body, and fit it to live through a greater range of circumstances; they improve its means of self-adjustment-a point which requires deep consideration in education. Medical men, when consulted relative to the regimen of children, and even of adults, are too apt to recommend exclusively warmth, regular diet, and exercise, proscribing all extremes. This may prevent tender children now and then from taking cold, but, on the whole, more is lost than gained by it. Let us never forget that all men are often hurried from one extreme to another by necessity, and that this sort of oscillation preserves or accumulates vital force.

There is a limit to the utility of change. It may be excessive. HIPPOCRATES alias speaking of the climate of Asia Minoral and Western Asia compared with Greece, crowned indeed with snow-covered mountains, but situate in a latitude where the general range of changes only extended from the temperripen. In countries not known to the Greeks, but this day for them was not then on in Pekin and Petersburgh, excessive change Blooding, and strong purguities, and of it illuste more favourable to life than the active remedies, he did not spare to emp

have occasion to show that life is not only inhabitants of a city or a small village. A less valuable, but, on the whole, shorter in medical man always saves many lives and Austria and other countries, where paternal much time in sickness; but in a neighbourgovernments enforce hygeinic laws, but de- bood, or in families where he can command prive their subjects of liberty, not allowing all the resources of hygeine, his practice them to bring up children for themselves, must be much more successful among adults. than in England, where the government has and rescue twice as many children from in-attempted so little towards raising the popu-lation to its present pitch of vitality by di-scribes most advoitly. Officers of dispensaries and hospitals will bear this out. In fine, all modifying agents act less on "But," some may say or think, "we live the individuals existing than on those form- by drugs; the present public will pay noing, and Europeans differ from each other thing for our sanatory precepts; they know more in size, form, and faculties, than the more of large green, purple, and red glass Asiatios, because - " Plures corruptiones globes, than of the physiology of health; contingunt in seminis coactione quam tern-they think more of Morison's murdering pra sequenter variant, quan at eadem pills, or St. John Long's caustic liniments. than of minute precepts about the air and HIPPOCRATES has described all the forms food by which they live and breathe. Besides, of sickness, and the signification of every why study hygeine, when, by promoting the sign, with an unapproachable exactness. He sign, with an unapproachable exactness. He would have estimated the pathological dis-ber of patients?" Gentlemen, I know that cor generous profession—Louis, and Carswell, at their real value, will not, for a moment, harbour sentiments petilic health, and if the pertisance of our lide constantly closed; when roused from craft is at variance with the public good in the sleepy state in which she lies, she the name of God let it be abeliabed, let us answers correctly; no convulsion or parabetake ourselves to something else. Happily our interests are the interests of the community: in proportion to the health and strength and knowledge of England, it has flourished, and will flourish, and in its prosperity or reverses we shall participate. In patriotism, also, litprocaates was our pattern. He pointed out the sources of health and improvement to mankind. He remained to the last, true to the fortunes of the small island on which he was born : he refused to go to the court of Persia, because he preferred serving Greece, and his disinterested exertions during pestilence ob-tained for him a place in the Prytaneum of Athens.

HOPITAL DES ENFANS MALADES, PARIS.

RESEARCHES INTO THE DISEASES OF CHILDREN.

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY.

TUBERCULAR MENINGITIS.*

Child ten years old; symptoms of tubercular peri-Child ten years out; symptoms of topercular per-lonitis; headache, returning with irregular accesses, and sometimes accompanied by billions vomiting; dulness; morority; after three mouths, constant headache, billions vomiting; mumbress of the hinds, delirium, coma, general convisions; death at the end of seven days; tobercles found in the meninger, longs, broaching glands, and perlouseaus.

CASE 3 .- Clemence Fournier, an orphan, ten years of age, was attacked at the age of seven with confluent small-pox, of which she still carries the marks; for the last three months she has complained of pains in the head and abdomen. Admitted into the hospital on the 14th June, 1835. She did not present anything more than the symptoms of tubercular peritonitis, and some uncertain signs of pulmonary consumption; up to the end of June we did not observe any notable change in her condition, beyond a sadness and depression of spirits that seemed quite disproportionate to the patient's sufferings, and two or three attacks of headache, without any other trouble of the cerebral functions. During the last few days of the month the moral and physical depression became more and more severe, with intense headache, and slowness of the pulse. Leeches behind the ears.

July 5. The headache has disappeared,

We exist, as a body, to promote the but the patient is dull ; she keeps the eveson of our lide constantly closed; when roused from altewers correctly; no convulsion or para-lysis of the limbs, but the muscular force is excessively depressed; pulse irregular, 96; the diarrhosa which existed for several days has given place to obstinate constinution. In the evening, return of the headache, which the patient describes as having its seat in both temples.

6. During the night and the morning, violent deliram and agitation, rendering it necessary to employ the struit-waistcoat: at the visit, however, she answers all questions addressed to her, and puts out the tongue when required: she complains much of headache and feebleness of sight in the left eye, whose cornea is perfectly transparent, and the pupil neither contracted nor dilated. On the other hand, the surface of the right eye is bathed in a puriform liquid. The sensibility of the skin is obtuse at both sides of the body, and the muscular force greatly diminished; the patient is unable to grasp an object firmly in either hand; the head is thrown backwards, and she atters an acute cry whenever we attempt to bring it to the natural position; there is no evidence of pain occupying the dorsal or lumbar regions; the patient can sit upright without difficulty: the pulse is moderately strong, 96, as yesterday; the diarrhum has now returned, and evacuations are sometimes involuntary. During the day, low delirium; the child is unable to recognise her relations.

7. Come; she does not answer when spoken to; the cyclids are closed; the pupils largely dilated; the limbs are in a state of resolution, and when lifted up are seized with a trembling motion; the muscles of the neck, on the contrary, present a tetanic degree of rigidity, and render the head quite immoveable; pulse 100; no stool; urine excreted involuntarily. Six leeches, three to the right temple, and three behind

the right car; a blister to each leg.

At three o'clock p.m. the patient was seized with general convulsions, which persisted for about an hour, and then terminated in death.

Body examined thirty-eight hours after Death.—Temperature of the Atmosphere, 20° R. (77° Fahrenheit).

External Habit. - Body lean; cadaveric rigidity very well marked; abdominal parietes of a greenish colour.

Cranium and Vertebral Canal.—The brain and spinal marrow had been removed from their cavities with their membranes, and left on the table of the dead-room for at least six hours before their examination by M. Jadelot in presence of the pupils. The dura mater does not present any-thing remarkable. The arachnoid at its free sur-

[.] Continued from LANCET, No. 645, page 575.

face is moist, and conserves its normal trans. She with of August, however, without any parency; the pia mater is infiltrated with a known cause, she was saided with comiting, great quantity of serouity. In its tissue we followed by intense basedache, fever, and conark a great number of tabercular gra- delirions; in the night of the 5th, she sank nulations, offering the same physical characters as in the cases already reported. On the anterior part of both hemispheres, to the extent of about a square inch on the right side, and half an inch on the left side, the pia mater is infiltrated with a yellowish substance having the consistence of chalk. This substance penetrates with the membrane into some of the anfractuosities, and here it is impossible to separate the pia mater, especially on the right side, without removing with it a portion of the cerebral pulp. Between two convolutions of the convexity, we find a tubercle, not larger than a good-sized pea; the cerebral mass is almost reduced to the consistence of jelly; but as this softening is not accompanied by any change of colour, and is general, it probably depends on putrefaction. The spinal marrow is equally softened. It does not contain any trace of tubercles.

Thorax. - Both lungs contain a great number of miliary tubercles; the brouchial glands are tumefied, and transformed into tubercular masses.

Abdomen.-The epiploon, thickened and studded with tubercles, adheres to the anterior wall of the abdomen, and to the convolutions of the intestinal tube, which are also united by false membranes that contain small white tubercular deposits. The pisms to the lower extremities. sub-peritoneal cellular tissue of the intestines, the mesentery, the liver and the spleen, -all these parts contain numerous tubercles. The interior of the intestinal canal was not examined.

TUBERCULAR MENINGITIS TERMINATING IN ACUTE HYDROCEPHALUS

Child eight years old; antecedent measles; de-pression of spirits, and dulness; headache and fever, returning by freegular accesses during three months; returning by tregular accesses during time adminst the symptoms of acute hydrocephalus; death; gra-natations in the pia mater; emission of turbid serum into the lateral ventricles; softening of the white central parts; pulmonary inherens.

Case 4.—A young girl, eight years of age, habitually of good health, of lymphatic temperament, contracted the measles near the end of April. During the three months following the disappearance of this exanthema, which was very irregular in its march, the patient frequently complained of pain in the head; she became sad, dull, and was attacked from time to time by accesses in gular fever. Towards the middle of stant, with pain in the abdomen and consti-pation; a tew lesches were applied to the trunks. On passing the pulp of the index anns, and mustard poultices to the extremi- finger along the surface of the arachnoid, ties. The symptoms were dissipated by these we feel a slight resistance at the points corremedies, and the child seemed to have re-responding with these little masses. On de-covered her original gayety and health. On taching the arachnoid and pia mater from

into a state of deep stupor; on the following morning, being transported to the hospital, she presented the following symptoms:-

Dorsal decubitus: alternation of paleness and redness of the face; complete loss of consciousness; the coma is from time to time interrupted by low cries; the globes of the eye are constantly agitated by convulsive movements; the pupils dilated and immoveable; the faculty of vision completely destroyed; there is trismus, grinding of the teeth at intervals; foamy saliva, tinged with blood, issues from the mouth. The superior and inferior members are slightly rigid; the sensibility obtuse at the right and left sides of the body, equally; no nausea or vomiting since yesterday; the child passed two or three involuntary stools during the night, after the administration of a purgative; the abdomen is retracted and indolent; the skin is dry, flaccid, and rough on the limbs; the heat moderate; pulse small and irregular, 132; the respiration accelerated, 52 in the minute, and often accompanied by dilatation of the nostrils. The chest gives a normal sound under both clavicles : on auscultating the patient we hear nothing but some mu-cous rale. Twelve grains of Calomel, in four doses; a large blister to the head, and sina-

At two o'clock p.m. the cries had entirely ceased; the face is now pale, and covered with a cold sweat; the trismus is very violent: the eveballs immoveable, and directed outwards; the sensibility and motility present the same disorders as before mentioned. The stools are involuntary; pulse 130. In the evening the coma gradually became more deep, and the child died at one o'clock after midnight.

Body examined fifteen hours after death.

External habit .- Body thin; a few phlyctenæ on the scalp, produced by the blister; no rigidity of the body.

Skull .- The cranium is well formed: its parietes are rather thinned than developed; the dura mater is in its normal state; the longitudinal sinus encloses a dark coagulum of blood; the great cavity of the arachnoid membrane contains about an ounce of serum; under the layer of this membrane that covers the cerebral hemispheres, we observe a multitude of points of a yellowwhitish colour, some isolated, others confluent, and forming by their union small the brain, we can distinguish clearly these that depression of the spirits and moral granulations, situate in this last membrane, and presenting a cartilaginous degree of consistency. They are more numerous at the right side than at the left, both on the convexity of the hemispheres and at the base; and are particularly confluent at the fissure of Sylvius on the right side. They are manifestly distinct, both in colour, form, and seat, from the glands of Pacchioni. gelatino-albuminous substance exists at the base of the brain, near the decussation of the optic nerves : the lateral ventricles are distended by three or four ounces of turbid serum; the posterior cornu on the left side, and the pes hippocampi on the right side, present a ramollissement of a creamy ap-pearance; the cortical substance of the hemispheres is slightly coloured, and the white substance pretty well injected; the cerebellum and pons varolii are healthy. The spinal marrow was not examineds

Neck and Chest .- The cervical ganglia, epiglottis, larynx, and traches, do not present any alteration; the bronchial glands are transformed into tubercular masses; the serous membrane of the thorax is not adherent at any point between the lungs and thoracic wall; the right lung is studded with tubercles; some, like gray demitransparent granulations, others presenting a duli point in their centre; others, finally, of a yellowish white colour. We do not observe any cavity; the pulmonary parenchyma appears healthy in the intervals of the tubercles; the left lung also contains a great number of miliary tubercles, most of which lie immediately below the pleura. The pericardium, heart, and thoracle duct, are healthy.

Abdomen .- Small tubercles are disseminated throughout the peritoneal lining of the intestines, the liver, and the spleen; the parenchyma of this latter viscus is studded The pancreas and with them like the lungs. kidneys are free from all alteration. The mesenteric ganglia are not developed; only two or three are changed into tubercular matter. The gastro-intestinal mucous membrane is healthy.

In the first of the two cases just reported, the chronic stage, which so frequently characterizes tubercular meningitis, and its passage from the chronic to the acute form, are well marked. If we look to the cause under

character which so often attends and points out the commencement of cerebral disease in children. In the present case, however, the diagnosis must have been difficult, for the child suffered at the same time under chronic inflammation of a similar nature in the abdominal cavity; hence the frequent pain in the abdomen, diarrhos, &c., to which the headache and torpidity might reasonably have been referred, and to which they would certainly have been attributed by M. BROUSSAIS and his followers. The symptoms of chronic meningitis continued for a fortnight after the child's entrance into the hospital, when those of the acute stage suddenly declared themselves. What were they? Bilious vomiting, exasperation of the headache, falling of the pulse, and constitution. we insist strongly on these symptoms. Although, taken separately (abstraction made of the headache), they seem to have no connection with cerebral disease, yet, when united in the same subject, they are a certain index of inflammation of the meninges or the brain in cases where some prodrome has existed, as in the present case; and even when no premonitory phenomena has been observed, they afford the strongest presumption of the existence of meningitis. We have not yet had time to make an analysis of the cases we possess of meningo-cenhalitis, in order to determine the value of bilious vomiting as a symptom of the development of this disease; but we can affirm that it exists in a vast majority of cases, and is a most valuable sign. In the case we now speak of, it may be said, "The vomiting took place in a child affected with peritonitis, and was, therefore, of no value as a symptom of cerebral disease; inflamnations of the abdominal cavity frequently produce vomiting in children, and may have been the cause in the case of Clemence Fournier." This reasoning is specious; we have often heard it employed, but its refutation does not require any great effort. The vomiting, if it existed which scrofulous inflammation of the cerebral alone, would certainly rather indicate abmembranes was developed in the present case, dominal disease than inflammation of the we find nothing to which we can attribute it brain, but it must be considered in connecbut the antecedent small-pox, though it is tion with other symptoms. Why did the very doubtful how far this disease may influ- pulse, at the same time, fall in frequency, ence the deposit of tubercular matter in any and the diarrhosa give way to obstinate conorgan. The symptoms of the chronic stage, stipation, if the vomiting depended on an which lasted three months at least (and per- increase of the abdominal inflammation? It haps longer), were energy headache, and is impossible to connect these latter symptoms with peritonitis; they are, on the contrary, well-known phenomena of meningitis, and show that the vomiting must here, as in a vast number of other cases, he attributed to sympathy with the brain. It is unnecessary to follow this case through the other symptoms; the only one we would remark is the violent delirium with which the child was attacked on the night of the 6th. It is strange enough, but certainly true, that inflammation of the cerebral membranes seldom gives rise to severe delirium in children, and in a great many cases the intellectual faculties remain undisturbed during the whole course of the disease; in the present case the delirium was not attended with any febrile access; the skin was cool, and the pulse only 96.

The second case presents several traits of resemblance with the former one; here also we find a prodrome extending from the month of April to August (three months), and consisting in headache, with irregular accesses of fever. The passage from the chronic to the acute stage was also marked in the same manner, by bilious vomiting and exasperation of the headache. As to the other two symptoms, constination and slowness of the pulse, it was impossible to determine whether they existed or not, as the child was not brought to the hospital until forty-eight hours after the acute attack, when she was in a state of coma. The other symptoms followed each other in rapid succession, without presenting anything worthy of notice; on the 6th the pulse mounted to 132. We merely mention this, because some systematic writers describe the last state of acute hydrocephalus as characterized by slow pulse; this is certainly an error. In a great majority of cases the pulse rises, towards the end of this disease, to 120, 130, 140, or even 150; it is always above 100; we would also direct attention to the absence of contraction of the limbs, although the forms, and a portion of the lateral ventricles, were remarkably softened. Meningo cephalitis rarely is fatal in so short a time as in the case now under consideration. The disease commenced on the 4th, and the broken by a blow or a kick, there is not child died in a state of come at midnight on the 6th. In most cases the disease lasts from seven, eight, or ten, to twenty-one days. days. P. H. GREEN.

OX

FRACTURES OF THE PATELLA.

WITH PROPOSALS FOR A

NEW PLAN OF TREATMENT.

To the Editor of THE LANCET.

Sir,-I send the subjoined observations for insertion in your journal, if the proposal by which they are accompanied be worthy of attention.

Fractures of the patella must be considered as rather serious accidents, when we reflect on the rarity of their osseous union. From the retraction of the upper fragment of the bone, in transverse fractures, by the powerful muscles connected with it, and from the difficulty of keeping the broken surfaces in steady apposition by the ordinary means employed, the union is generally by ligament. The length of the uniting medium varies from half an inch to three or four inches, but, if it be more than half an inch, the patient can never walk securely.

Although such fractures are generally united by ligaments, yet the possibility of osseous union is now placed beyond doubt, by the number of instances recorded, and, it is owing to the inadequate means of treatment that osseous union is not more frequently effected. It is highly probable that, if we could scrupulously fulfil the indications of cure by proper modes of treatment, there is no fracture which, in ordinary circumstances, would not unite by bone, not excepting even fractures of the neck of the femur within the capsule. Deficient vascularity, I suspect, is not the true rationale of non-union in such cases. There are still some who seem to think that the organization of the patella is different from that of all the other parts of the osseous system, and that therefore, when broken, it must unite as regularly by ligament, as do the other bones by bony matter. It would be somewhat strange were the result of their practice in any one case to belie their theory.

Sir C. Bell is of opinion that the cause of the fracture exercises a material influence on its union. "In the common case," he says, "of fracture of the patella by the sudden action of the quadriceps extensor, the pieces are separated without that degree of violence which is necessary to produce reunion by bone. But, when the patella is only less retraction, but the injury, the bloody effusion, the tumefaction, and the rigidity of the parts, resemble that which attends the fracture of any other bone, and M. GUERSENT tells us that he has only ob- the fragments unite by bone." If he had served a single case where it exceeded thirty merely said that, in fractures from direct violence, there is less retraction than in those

from muscular contraction, and that the upwards in the same direction, and made to former more frequently unite by bone than the latter, he would have been more cor-rect. It is not from the greater violence which the bone sustains in fractures from blows, but from the capsule to which it is attached being less torn than when the fractures result from muscular contraction, that it more frequently unites by bone.

The chief points to be attended to in the treatment of fractures of the patella, as in all other fractures, are, 1st, To keep the fractured surfaces in apposition, and, 2ndly, To prevent motion between them. The means generally employed. I am inclined to think, are not adequate to fulfil these indications. The great objection that may be urged against them is, the undue degree of pressure which they exercise, either on the whole circumference of the limb, in the vicinity of the fracture, and thereby impeding the circulation below, or, by being of trying this method; but, from its success confined to a point endangering the super- in that case, I feel warranted in recomstance is a strong objection to Mr. Mog-lam, Sir, your obedient servant, ridge's ingeniously contrived apparatus. Mr. Mogridge, however, by this apparatus, obviated an objection which applies to all the other plans of treatment, viz., the circular compression, and consequent obstruction to the circulation in the limb.

In Sir Astley Cooper's plan (which is the one now generally employed), a belt is buckled round the thigh, immediately above the patella, and from each side of it a narrow strap passes down over the sole of the foot; but when this apparatus is put on lightly. which it must be when there is much retraction, it causes great swelling of the limb, and much uneasiness to the patient. Mr. Amesbury has improved on this plan, but his apparatus is so complex and expensive, as to preclude its use in the ordinary cases occurring in private practice.

The plan which I now propose is both simple and easily applied. It consists of a wooden splint, reaching about seven inches above and below the knee-joint, and from four to five inches in breadth. To the lower part of it is attached, transversely, a narrow piece of wood, extending about two inches beyond either side of it, giving it the appearance of a cross. This transverse piece should be so placed, that its upper edge, when the splint is applied, will be opposite the spine or tubercle of the tibia. The limb being bandaged from the toes up to the middle of the thigh, the splint, padded with towor cotton, is applied posteriorly, and fixed by several turns of a roller. The fractured surfaces are then approximated, and another bandage. two inches broad, is passed two or three times round the thigh, above knee, and then carried obliquely above the upper fragment It is then brought round it, and carried cordingly I was admitted to examination.

turn round the thigh, at the point from which it started. The above manipulation is performed round the other transverse process, and repeated on each side successively, until the bandage, which ought to be several yards long, is expended. The position of the limb and trunk is then attended to, as in the other modes of treatment.

In applying the splint, we must take care (as already stated) to have the upper edge of the transverse piece of it placed opposite the spine of the tibia; otherwise the bandage which is last applied, is apt to slip over the patella. If we attend to this point, however, we can produce considerable traction downwards, and keep the fractured surfaces approximated, without danger of the bandage slipping, and with very little uneasiness to the patient.

I have had but one opportunity, as yet,

London, February 1, 1836.

APPLICATIONS AND EXAMINATIONS FOR A MEDICAL DEGREE.

AT EDINBURGH, ST. ANDREW'S, AND GLASGOW.

To the Editor of THE LANCET.

SIR, -- I am induced, more particularly by the statements in your last two numbers relative to the conduct of the Examiners of Apothecaries' Hall on a late occasion, to enter into the following personal details, for which, however, an apology to the public may be necessary.

Some years ago 1 offered myself as a candidate for the "Summi in Medicina Honoros," as their dispensers call them, of the University of Edinburgh. Before any examination was begun, it was objected that my Paris certificate was insufficient for its object, viz. to count as one year out of the four required for the course of study. as the certificates, if I remember rightly, are sent in some months (certainly some weeks) previous to the day of examination it is the business of the professors to see that they are sufficient, or to return them, and acquaint the student or candidate with what fact. This, however, was not done in my case; but, I presume, considering the omission to be their own (for I was not aware that I had not studied long enough), the of the patella, and downwards, underneath examiners probably were desirous at least one of the transverse processes of the splint. of appearing to "make up for it." and ac-

The examiners were, Professors Alison, so seldom esteemed by the public? Not be-Fraham, Monro, Duncan jun., Home, and Hope; and if I may be allowed to express an opinion of their merits, I may state that I have placed them pretty nearly in the order in which they should stand. After about two hours' examination, and ten minutes' deliberation among themselves. Dr. Alison presented to me my certificates, stating that the Examiners were not satisfied with them, and, consequently, that he should either recommend me to study for another month or two, or (what would be better) come up for examination in the following year. As I had reason to believe that the shortness of time occupied in my studies, and the circumstance that I had shown some disrespect, though perfectly unintentional, * towards one or two of the examiners, operated in some degree in producing this decision, I resolved to appeal to another tribunal; and, accordingly, I was soon on my way to St. Andrew's,-St. Andrew's! not, as formerly, the mercenary St. Andrew's, but St. Andrew's the reformed,-the St. Andrew's which then professed to examine into the moral character of the candidates, and to require from him some knowledge of the Greek. Alas! " Dum loquimur, fugerit invida actas,"-everything changes in this world; and so sudden a change from the basest kind of prostitution to consummate virtue, would lead us to believe that miracles have not ceased.

But respecting the reasons which influenced the Edinburgh professors in recommending to me a second examination, more remains to be said. Dr. Hope, as is custowary, I believe, wrote to ask me if the thesis which I had sent in, was intended for publication. I replied, no, not in Latin, but in an extended English form. Dr. Hope, as well as Dr. Duncan, and, probably, all the professors, were aware that I had long been engaged in making some inquiries into the blood; and I have little doubt that the intention which I expressed not to publish the Latin, but to extend the thesis, and publish it in English, might be considered as presumptuous in a student who had not yet passed an examination.

While coinciding with Gibbon in the opinion that an author is generally the best judge of the merits and defects of his own work, I also consider that a man is generally the best judge of his own qualifications and conduct in the case in question. Why, then, is his opinion of himself or his book

Knowing that I had studied the profession most attentively, both by reading and by practice, for many years, I did not go for six months (as the custom was) into a grinder's shop, to have my mind "filed," as Shakspeare calls it, to the usual shape. I contented myself with six lessons on the general plan of proceeding, and found those too many.

I went to St. Andrew's next, because rather more classical knowledge seemed to be required there, under their new regulations, than either at Edinburgh or Glasgow. Besides, no further attendance on lectures was necessary before admission to examination. Lectures on the theory of physic, and on speculative physiology, are not near so well calculated as reading and comparing different authors, to increase our knowledge of medicine. Where lectures are illustrated by experiments, the case is different.

Professor Briggs, after examining my

cause he may judge incorrectly, but because he has not candour enough to acknowledge the defects. This may be the case with myself.

But did I answer all the questions put to me at the examination? Certainly not. Replies to some of them seemed as impossible as an answer to the question put to a student by the Society of Apothecaries,* viz., " How many protoxides of mercury are there?" I answered, I think, nearly twothirds of them, but to give my adversaries fair play, let me allow that I answered only onc-half. But when it was found that I did not intend to publish my thesis in Latin, it was not even examined, as I have good reason to know. I had written this Latin document myself. It was merely corrected by a master previous to being placed in the hands of the professors. I naturally enough, therefore, depended greatly on this "for passing;" for the corrections being made not in sentences, but in individual words, I could pretty fairly consider myself in the light of its author, in language as well as in matter. It extended to fifty pages; but this labour went for nothing, though, as I subsequently found that the thesis always weighs as nought, I must not here censure the examiners. However, as it had not been twice written, and the corrections were occasionally visible, this circumstance also may have been considered disrespectful, though quite unintentional on my part.+

[.] LANCEY, Jan. 16th.

[•] LARCEY, Jan. 16th.

+ I may add here that I only took out one ticket fram each Examiner; but I believe most students take out two, though this may not have inflaenced them. Again, though in the Latin questions I was not perhaps as quick or perfect as I stiontd know been, yet I save the English of Latin put to me which I had never seen before, whom the childness with much less knowledge of Latin, and, as I think, with less knowledge of physic generally.

^{*} Time of the questions of Drs Home and Monro were so extraordinary, that they caused a little levity on my part; and some of those of Dancan and Hope on my part; and some of those of Dimean and Hope were so snappish, that they produced somewhat sharp results. Moreover, i had before thoughtlessly told Professor Turner that I should try Glasgow if I failed at Blimburgh. This was not very complimentary to his intimate friend, Dr. Alison, who probably, as well as all the Edinburgh Examiners, was informed. of it.

certificates, was, I think, at first inclined to plogist. The Revne Médicale of Paris has admit me to examination. But when in reply to his inquiry, Why, since I had studied at Edinburgh, I did not graduate there? I answered, " that having been once rejected, I intended to graduate elsewhere," rejected, I intended to graduate eisewhere, "correct, I cannot but cherish a neiter that, the case was altered. Observing (as I con-science or later, it will come to be considered ceived) this alteration in his sentiments, I a standard work on the subject. did not press the matter; but at once departed elsewhere.

At first sight this hesitation of the Professor may seem to be confirmatory of an in London, for students who may be dealt alteration in the University, as regards imjustly by at medical examinations. Think pecuniary considerations, the expense of of the College of Physicians rejecting Armthe diploma being £35. But he had to strong and Mason Good! perhaps for some support the new character of the institution, petty questions which those distinguished and I beg therefore to express my regard men would have lost time in honouring for his conduct. If I had passed at St. with a moment's attention. But public public would have said that he had sold me is so vague a term, and some examiners are the degree; particularly as morality had so fond of showing their powers of crossonly just begun to exert an influence at St. Andrew's. It was of course necessary to its reputation, that at least the first few years of its new life should be passed in a state of watchfulness. But not even then do tion in the public mind. Poor St. Andrew's! I fear the £35 were wholly lost to thee in any thape, for centuries may elapse ere the blot upon thy name can be effaced.

I called upon Professor Jeffray at Glasgow. wishing to pass my examination there before the summer had expired, but he told me that I was then too late, as it was necessary to take out two Professors' tickets before I could he examined. He, too, asked me why I did not graduate at Edinburgh, so that this ations? well-known anatomist, who was one of my examiners at Glasgow, indifferent to the opinion of the Edinburgh professors, dared to admit a student to examination, and to pass him, whom the latter had thought fit to reject, for I was successful at Glasgow, and without any " grinding." As my rejection at Edinburgh was known to Professor Jeffray, it was probably also known to Professor Thomson, the other examiner. therefore consider the degree I hold the more creditable to me, since the previous rejection could not have operated with the Glasgow professors at all in my favour.

I then went to Edinburgh and finished my book, which was already partly printed, and advertised it in the Scotsman, as written hy " H. Prater, M.D., of the University of Glasgow." Obliged as I am to the Glasgow professors for their degree, still on that book, -- which, notwithstanding its bad arrangement and inequalities, has been regarded as one of the most profound and original works on the subject since the time of Hunter,-do I rest my chief claim for consideration as a physician or a physi-

done me the honour to express, in their number for June last, a high opinion of its merits, and with all its defects, and these hope another edition will allow me to correct, I cannot but cherish a belief that,

And now that medical reform is under discussion, I would beg to recommend to those who are in power, a court of appeal, Andrew's after being unsuccessful at Edin-examinations, as THE LANCET has suggested, burgh, he might have been afraid that the would be best and safest of all. Medicine examining, or their "extensive knowledge," (as was the late Dr. Duncau, particularly,) that when unchecked by public observation they may occasionally encroach even on the province of such an examination as would regenerated characters always recover sta- be given to apprentices by tea-dealers, or oilmen, or unrsery gardeners, or God knows what other tradesmen, and call the examination one on " materia medica and the practice of physic!" In the classics and the exact sciences, there is no room for these excursions. It cannot be too often repeated that a check of some kind is required on medical examiners. What reason have we to consider such men as above the influence of personal prejudices, or sordid consider-

I conclude by expressing my admiration of the noble stand which "the rejected candidate" has made against the "Pot-I-carriers." Perhaps his course was better than mine. I have the honour to be, Sir, your very obedient humble servant,

H. PRATER. 12, Dalby Terrace, Jan. 25, 1836.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Feb. 6, 1836.

Mr. RICHARD QUAIN in the Chair.

DR. JOHNSON said he had this week seen a most interesting case, which at the same time had puzzled him more than any he had ever before seen. The subject of the case, who had led an active public life. was the only surviving sister of the late Mrs. Siddons, and was now in her 76th year. Two years ago, this lady consulted him (Dr. J.) for a very severe and obstinate pain at the back part of the head, which had existed for upwards of twenty years. She was then

^{*} Prater on the Blood. Highley, Pleat Street.

a fine-looking active woman, full of spirits, and had invited the doctor to join a large dinner party, which his professional avocastions prevented, and from that time until last Monday he had lost sight of her. Time and suffering had now wrought a great change in her person, which was reduced almost to the bulk of a skeleton. Her features were shrivelled, and indicative of great distress. Three months back a great difficulty of speaking came on, followed, in the course of a few weeks, by difficulty of awallowing, both functions gradually de-creasing in power up to the last three months, when she became totally incapable of articulating and swallowing, and was, when he (Dr. J.) saw her for the first time during the present consultation, dying of inanition. The tongue presented a shrivelled condition, and was incapable of tiful at Guy's. motion; in its centre were several small knotty prominences. Hunger and thirst, phenomena of considerable interest, were absent. Most of the other functions of the body were apparently healthy, the secretion from the kidneys and alimentary canal being necessarily scanty. The intellect was perfeet, written answers being returned to inquiries, except to her attendant, who understood what she attempted to utter by the movements of the lips. He (Dr. J.) conceived that there was paralysis of the nerves which impart to the tongue the power of motion, and those which produce articulation, the eighth and ninth pair, these having their origin from that region of the head which had so long been the seat of suffer-The remedial means adopted at present had been first to support the system by nutritions liniments, adding to the first. fifteen drops of laudanum, which succeeded in producing some sleep. On the second day, two lavements were administered, and on the third (Wednesday) a small quantity of broth, with considerable difficulty, was passed down into the stomach, which produced, as that organ was greatly contracted, some uneusiness, from the distention that followed. This plan of treatment, since Monday, has been productive of some benefit, and today (Saturday) slight motion was perceptible in the tongue. The lady, although advanced in years, was anxious for life. Since the administration of the broth, a tenderness of the abdomen had supervened, which had been combated by sinapisms. An exceeding captous motion also had come away. Not a little curious to remark, after the first wix or seven ounces of broth were passed down, a vomiting of pure bile succeeded, without its containing a ringle drop of the broth, showing the remarkable power of the system, when only functionally and not or-ganically deranged, to retain completely was offensive.

Dr. Appraon related a case, not very much in point, and remarkable only, though not uncommon, for the following particulars :-- A young woman, twenty-two years of age, was received into Guy's Hospital, a perfect skeleton, apparently labouring under irremediable organic disease of the abdomen, with an imperfect state of the uterine organs. A judicious administration and perseverance in the use of aperients, brought away, one after the other, stools much larger, collectively than it was imagined the contracted state of the whole alimentary canal would have allowed it to contain. Eventually her health was perfectly restored, and she grew fat, and became one of the sisters in the institution. She had lately had a relapse, attributable to her indulgence in the good things of this world, which are plen-

HARNEMANISM.

Dr. STEWART WAS now called on to furmish his paper on the operation of minute doses of medicine. After some judicious introductory remarks, the Doctor begged to be understood as condemning, without respect of persons, in toto, the blue pill plan, the Morison-pill plan, the bread-pill plan, and all other indiscriminate plans, which pretended to reduce to uniformity what was in its nature infinitely varied and complicated. A due variety of remedial measures, administered under the personal direction of medical men, was the distinguishing mark of rational practice. But even after allowing a choice of means, there have been very opposite ends proposed in their employment. The contra-stimulant and homoopathic systems stood remarkably contrasted, not only as to the doses of medicines, but also from there being in the former very little regard paid to the symptoms produced by the remedies, and in the latter the affectation of a great deal more attention than usual. Homosopathy comprehended not only the imitation of disease in the administration of remedies, but the diminution of the dose. With regard to this ingenious supplanting of disease, as recom-mended by Hahneman, he (Dr. S.) thought that there existed a delusion, the copy existing only in the mind's eye, while the reality was going on, uninfluenced by the phantom of physic which was to frighten it away. Looking at the liberal allowance of time which was made, often from a week to a month, between the doses, and calculating the comparative and relative agency of all the elements of a homeeopathic case, he (Dr. S.) concluded that it was not the small dose of medicine, but rather the large dose of time, which worked the alleged cures. As that which was appropriate for the support to the principle of bouncementhy, the plan of the body, while it rejected that which of treating similar similars, there was nothing in it that was new. Diarrheea had frequently been cured with purgatives, go- | tion for the benefit of the patients, givnorrhica with irritants, and sallors were ing no privilege in the wards. even said to cure old gleets by contracting a greedy and disgusting law was carried on fresh clap. With regard to the question, the 2nd of June, 1835, by a majority of 30 whether the doctrine taught by Hahneman to 29, in a full meeting of governors. But was quackery or not, the answer was to be the exposure which attended no found in the reply to the inquiry, Is any part of the system concealed, or is it laid before and at this adjourned meeting it was unanthe profession in a manly way, and open to mously expunged, Dr. Chakes on this inquiry and experiments? Medical societies occasion merely intimating to the independent afforded good tests of such questions. They majority of 36, that it was not now either served the purpose which Frederick of Prushis or Sir Benjamin's wish to place such a sia employed with the philosophers whom law on the books. The result was of course he invited to his court, saying that he knew very gratifying to the few governors who how to squeeze the orange and throw away stood forward to advocate the enlightened the pulp when he got them there. Medical side of medical polity. Practitioners may societies were capital squeezers, though now visit the wards of the hospital, both for they did not always obtain much juice. pated to-night.

ST. GEORGE'S HOSPITAL.

THE NEW CODE OF LAWS.

LAST year we devoted an occasional page to reports of meetings of the governors of this hospital, to form a new code of laws for its government, and did some good by exposing to public view the proceedings of the cannot pretend to guess. Much angry dismedical junto who had obtained sufficient enssion ensued, and the "expulsion" lawinterest among the subscribers to commit wise and provident measure-was carried. all kinds of corrupt and illiberal acts, in wielding the patronage and managing the like way, contended that the govern-affairs of the institution. The final com- ors ought to submit to the adoption of mittal of the new laws was, at a certain this law, because it was copied rerbatim stage of their consideration, adjourned until from the law-book of the Law Association. January 1836, and that time having arrived, Dr. Wilson could not see the justness of their discussion has been renewed, and we the precedent, and opposed it. For our are now prepared to give an abstract of the parts, we think it would be as correct to order fresh debates on their revision, and the wigs and gowns all round for the medical results.

day, January 11th. Mr. HOLLAND in the Howship voted for the clause because Dr. Chair. The first matter discussed worth mention was the motion Dr. Wilson intrusted to the care of Dr. CHAMBERS, for the lawyer, whether an action at law would expunging those words from law 11, which not justly lie against the nine individuals declared that medical governors should not who might "expel" a governor, and subinspect the hospital "for the purpose of obtaining medical and surgical instruction, under colour of such inspection." This law was originally intended by Sir B. Bredie's ing, and it was generally agreed that the laws worthy party, to keep every medical visitor of no other hospital contained a similar out of the hospital, unless he had paid to the medical officers an enormous fee-a subscrip-

the officers, and with the object of seeing The drift of the paper was for the most such practice as its walls afford. Dr. Wilpart lost sight of in the speeches which followed, and as the subject is postponed for opportunity of exposing the majority who future discussion, we leave to another oc- voted on the former occasion, and of pointcasion further remarks. The evening passed ing out the good effects of perseverance on off merrily, if not instructively. At least the part of a minority, and Dr. Wood took the cloud of silence which has hung over the care to obtain an explicit proviso that licen-Society for the last two nights was dissitiates in medicine and surgery should have "access to the wards of the hospital, at proper times, on the introduction of a Governor."

Attention was then called to a substitute for law 13, which related to the "expulsion" of governors at the caprice of the Brodie party,-or, as the excuse ran, for any conduct, in connection with the hospital, or any notorious public scandal, calculated to bring discredit upon the haspital,"-on the bricks and mortar, we suppose, for how anyhody but themselves could bring discredit either on the patients or the medical officers, we Mr. Fuller, the lawyer, in a businessofficers, because the barrristers wear them The adjourned Special Court met on Mon- in the law wards at Westminster. Mr. Wilson opposed it. Mr. TRIMMER, in an able speech against it, asked Mr. Bagshaw, lish their libelious reasons for the proceeding. As Mr. Trimmer offered no fee for the opinion, the lawyer declined answer-

clause. Mr. James Lane, Dr. Wood, and the governors had failed in electing a quali-Mr. ANCELL, also spoke against the law; RODERICK MACLEOD and Mr. BAGSHAW in s favour. The minority, however, Mr. RIMMER at their head, succeeded in getting appended to the clause the following declaration; —that no question relating to the expulsion of any governor shall be considered, or discussed, or acted upon, at any weekly board at which there shall not be present twelveyovernors, nor any question relating to the expulsion of a governor at any weekly board he carried by a majority of less than two thirds of the governors present."

Friday, January 15th .- Mr. Holland in the chair. Several amendments of no public import having been agreed to,

Mr. JAMES LANE moved as a law that, "No governor or governors shall circulate any notice or statement bearing date from the hospital, relative to any election, or tending in any way to influence the rotes of governors at any election, unless such notice or statement shall have been previously sanctioned by the weekly board." He said that at a late election of an assistant surgeon, six of the medical officers dated a circular letter to the Governors from the hospital, to the unjust prejudice of one of the candidates, and he wished to guard against the recurrence of such a proceeding, which tended to deprive gentlemen who looked forward to the offices of the hospital as a reward of their industry and professional attainments, of a fair chance of competition.

ROBERICK MACLEON acknowledged that the dating of the circular from "St. George's Hospital " was decidedly wrong, and attributed the circumstance to an "oversight."

Captain BAGNOLD observed that in respectable societies the office bearers serupulously avoided any interference in the election of coadjutors; he wished as much delicacy was exhibited at St. George's. At present the successors of medical officers were only looked for in the pupils of particular persons, without regard to their capability. The circular in question was evidently an attempt to influence the governing body at the eleventh hour, when reply on the part of a candidate was impossible.

Dr. Skymour on the other hand asserted that the governors of all medical institutions invariably referred to the medical officers the candidates for vacancies, and it was in fact the duty of the medical officers to interfere, in order to guide the votes of the governors.

Mr. ANCELL referred to the elections at the Western Dispensary in proof of the incorrectness of the statements of the last speaker. In that institution the medical officers made it their business to abstain from all interference in the elections, and he appealed to Sir B Brodle, who is connected with that institution, to say whether

fied individual. Altogether, the jealousies and private interests of the medical officers wholly disqualified them from electing their coadjutors, who stood a chance of rejection, exactly in proportion to the independence of their character, at least at St. George's hospital.

Dr. Wilson showed that the existence of two editions of the circular palpably ex-posed the character of the "oversight" suggested by Dr. Macleod. He also reflected on the circumstance of a copy of the circular being immediately sent for insertion to what he described as "a disreputable and contemptible periodical, with which Dr. Macleod was intimately connected, if not the avowed editor."

Ultimately the law was passed.

Monday, January 18th.

The meeting of to-day was, as is usual, opened with a prayer for charity, Mr. HOLLAND in the chair. The story of the grocer and his apprentice, who sanded the sugar and watered the molasses before devotion, was thus forcibly brought to mind. The room was said to be two-thirds packed with Sir Benjamin's disciplined men.

Mr. ELKINS' motion stood first-" That lists be taken of the majority and minority of such governors as vote on any matter decided at any weekly board, provided three governors present shall require it, and that such lists shall be entered by the Secretary as a part of In an able speech Mr. E. the minutes." pointed out the necessity for keeping a faithful record of the proceedings of the board, and on the general advantage of registering the votes on matters of importance, a proceeding to which conscientions voters could not object.

Mr. Monley seconded the motion. He thought the law would prove a salutary check on the votes of those who decided on questions before understanding them, as did many governors at present, thus often sacrificing the interests of the institution to party feeling.

Mr. JAMES LANE felt convinced that such a law would have prevented the extraordinary proceeding of the last meeting, when a motion which had undergone a thorough discussion, and was supported by the speeches of four of the medical officers, and was carried by 36 to 29, was rescinded. at the dicta of Dr. Chambers and Sir B. Brodie, who were not present. "Surely." Mr. L. said, "those 36 gentlemen could not, if their names had been recorded, have submitted to this degradation as voters." He also advocated it upon personal grounds. It had been stated in the board-room and in the wards of the hospital, by one of the medical officers, that in consequence of his (Mr. J. Lane's) factious opposition to these board.

laws, his brother the surgeon should never he had now to deplore, would have been be an officer of the hospital. He (Mr. Lane) was anxious to have his vote recorded upon every occasion, for he mover did vote factiously.

Mr. FULLER (the lawyer) opposed the motion, because no institution in the world afforded a precedent for it.

Dr. Wilson thought that publicity should be given to all the proceedings of the

A Governor (not usually an attendant) said he had heard so many arguments for the motion, and only one speech against it, (the world being too large to be searched for precedents, and arguments being wanting on the contra side, that he should vote for the motion.

Mr. ELKINS replied, and adduced several precedents, among others, the meeting of the Middlesex magistrates, on Mr. Rotch's business, when the votes were recorded.

The motion, however, was negatived by

a large majority.

Dr. Wilson next proposed that the physicians and surgeons " should meet in committee" at stated intervals, " to consider all matters relating to their office, and report proceedings to the Weekly Board." He considered the enactment essential to the proper conducting of the hospital affairs. A year and a half ago the medical officers were deputed to report on a proper site &c. for the erection of baths in the hospital, yet no meetings to consider the matter had ever taken place. The museum, also, was, by the new laws, placed under the care of the medical officers. The questions pending as to the medical schools of the metropolis, rendered it also imperatively necessary for the medical officers to meet, from time to time, in committee, to protect their common interests. Desirous, too, as he was, of avoiding personal matters, he could not omit alluding to the indelicacy of isming a prospectus, headed "St. George's Hospital," with his (Dr. W.'s) name attached to it, without consulting him, and in defiance of his written protest to the contrary.

Dr. SEYMOUR said he should oppose all such propositions. It would be attended with the greatest inconvenience to himself, and it was highly derogatory to the character of a high-minded physician to be compelled to adopt this specific course.

Mr. Nussey, one of the visiting apothecaries, considered the governors would have reason to be offended at such meetings.

Dr. CHAMBERS also opposed the law. At such meetings nothing but angry discussions could ensue. As matters now stood, disputes could be got rid of by a word, and if the governors enacted the clause, he must decline attending the Committee.

Mr. Stone was in favour of the law. Had it before been adopted, the whole of the dis-

averted.

RODERICE MACLEOR opposed the law because it would afford opportunities for gentiemen to " have a fling at one another.

Mr. ANCELL considered the arguments against the law to be entirely personal, and such as the Court could not properly enter-tain. The Court had recognized the medi-cal officers as a body, and delegated to them certain powers which it was incumbent on the Court to take care should be properly exercised. He regretted to hear some of the medical officers refusing to act with others because differences of opinion existed amongst them, and he thought the Court was in error in recognising dissensions in the medical staff, which it certainly would

Dr. Witang library that, after what had fallen from the library that that, after what had fallen from the library that the matter would end. The answer that Mussey he replied, that meetings of the medical officers do take place, meetings to call up the servants and to censure them, -without any reference to the weekly board of management. For instance; upon the recent election of a chaplain, the porter was called before the major section of medical officers, and censured because he was suspected of being favourable to the candidate whom that section did not support ! It was for the purpose of regulating the meetings of the medical officers that he proposed this law, and, moreover, to ensure the first step towards conciliation in the management of the hospital affairs.

The law was rejected by a large majority, and the meeting adjourned to the 22nd.

Friday, Jan. 22nd .- Mr. HOLLAND in the chair.

Sir Culling Smith moved that "In the absence of the two senior surgeons, their patients shall continue to be attended by the present senior assistant surgeon." In a mild, gentlemanly, and conciliatory address, the hon. Baronet besought the medical officers to return to the arrangement which subsisted prior to the election of a second assistant surgeon, and to remove the impression that it was intended to humiliate an officer who had served the hospital with zoal and ability for upwards of six years. The present arrangement, also, was detrimental to the best interests of the institution.

Mr. JAMES LANE entertained the same views, not doubting that the law would, he in accordance with those of Sir B. BRODIE. who pledged his word to Mr. Walker that the election of a second assistant surgeon should not in any way prejudice him, or disturb the existing arrangements.

Sir B. BRODIE made a statement respectventions, and their consequent evils, which ing his own conduct, in which he alluded to some paragraphs in the newspapers as at whose authority I can rely, that the patients justification of the proceedings of himself have not been seen for a week past. Sir, and his colleagues towards Mr. Walker. It was true that he had pledged his word of monr to the effect stated by Mr. Lane, and he should now be glad to have Mr. Walker's efficient services as his assistant, but his colleagues, without consulting him, had entered into a different arrangement. Sir Benjamin was twice called to order in his personal statement, but the chairman ruled that it formed a proper subject for discus-

Mr. KEATE, Mr. BABINGTON, and Dr. SEYMOUR, followed, the latter saying that the present arrangement was so perfectly symmetrical that he should certainly oppose its disturbance.

Mr. CUTLER considered that the governors would be guilty of great hautice to him, if they deprived him of a partition which he had enjoyed for twelve thousand.

Sir Current Better, to reply, observed that he had heard nothing which altered his view of the case. If it could really be shown that the symmetry of the arrangements would be destroyed, he should relinquish his proposal, but he had the authority of Sir B. Brodie himself that it would not. Bearing in mind that Sir Benjamin wished to have Mr. Walker's services, and that Mr. Walker was anxious to be Sir Benjamin's assistant, he could not conceive why the other surgeons should oppose an arrangement to which the parties most interested consented.

Sir Culling's motion was then put to the vote, and, of course, negatived.

Mr. Jones moved, " That the income of the present apothecary should not be reduced beyand his average salary for the last ten years." Towards the conclusion Mr Jones remarked that on inquiring of a governor why Mr. Hutchins, the present apothecary, was alone unde to suffer in his income, he received for a reply, not that he was an unworthy servant, for the contrary was acknowledged on all hands to be the case, but that he was "on the wrong side." Having no personal knowledge of Mr. H., but being acquainted with gentlemen on the strong side in that room, he had been afraid that this was the true cause; but Dr. Seymour had entirely disclaimed its correctness. He now, therefore, had no doubt that those who had the power to avert oppression would cordially support his motion.

Mr. Jones, however, was grievously in error. The usual minority alone supported Ms motion, which was of course negatived. Our reporter then goes on to state that on the question of adjournment being put,

Dr. CHAMBURS rushed to the table, foaming and furious, and thus addressed the pre-

my mind is perturbed, my spirits are oppressed, my feelings are assailed, and the business of the hospital is obstructed. The time of the medical officers is taken up in this Board-room by factious governors coming here to bring forward futile motions.

Dr. Wilson ross to order, but was overruled by the chairman.

Dr. CHAMBERS proceeded: -- by Gover-nors coming down here with factious motives, and bringing forward motions which they know cannot be carried,-when they know they will be beaten, two, three, four to one-four to one, and having no other desire than to take up the time of the medical officers in this Board-room, and causing the patients to be neglected. Having proceeded in the same strain for some time longer, actually livid in countenance, and foaming at the mouth, he turned from the table.

Mr. J. Lanz.-Sir, as you have thought proper to rule that Dr. Chambers was perfeetly in order in imputing factious motives to governors, I, as one of those who have given notices of motion, trust you will call on Dr. Chambers to state whether he alluded to me.

Dr. CHAMBERS.—Sir, I have no explanation to give. Mr. Lane-Then, Sir, you had no right

to make such accusations. (Great uproor.) The CHAIRMAN said, as Dr. Chambers had made so grave a charge and had thus left it, of course he would retract the objectionable expressions.

Dr. CHAMBERS did so, saying that he meant nothing personal.

Mr. LANE then said, that the inconve-

nience arose solely from the medical officers having been allowed to occupy nearly the whole time of this meeting in criminations and recriminations. The charge of factious motives he wholly denied.

The CHAIRMAN here interfered and said he should not allow this matter to proceed any further, on which the meeting broke up in great confusion, and with many censures on the conduct of Dr. Chambers, and some on that of the chairman.

Monday, Jan. 25.

Prayers.-Mr. Powers in the chair.

Mr. MORLEY wished to have some opinion as to the conduct of Dr. Chambers at the last meeting, but the chairman objected. Mr. M. then handed in a written paper on the subject, which was refused.

Mr. J. Lane moved the incorporation of two clauses of the Apothecary Laws. Feeling from what took place at the close of the siding officer:—Sir, I have a complaint to last meeting that those governors who make of neglect of duty. I have been into brought forward independent motions had the wards, Sir, and am told by a person on not the protection of the chair, he had determined on not attending this meeting, but on reflecting that the conduct of one individuals whose title to vote as a governor, he resolved to be present, party who profit by holding office in the inthough, with regard to his motion, he had no expectation it would be decided on its for public hospitals should be founded, and which should nlone be followed in the decider the present.

The CHAIRMAN begged Mr. Lane to proceed.

Mr. Lane did so, though with every doubt of a fair discussion. He then explained his views on the subject, but we are compelled to say that some deficiency in the notes before us prevents the arguments on the question from being sufficiently clear for publication. The tendency of the arrangement opposed by Mr. Lane seemed, according to the report, to sanction the entrance of pupils to the assistant apothecary, whose interest it would then be to attend to his pupils rather than to the regular husiness of the bespital.

Mr. BAGSHAWE contended that the meeting had not power to concede what Mr. Lane desired.

Mr. Benson (a barrister) differed from his learned friend, who he thought carried his special pleading and legal quibbling rather too far.

Captain Bagnold thought that the quibbling was not too paltry for the Old Bailey, but that they would be ashamed of it even at the pie poudre court at Bartholoniew-fair.

After an hour and a half's speechifying it was decided that the meeting could amend the clauses opposed by Mr. Lane.

Mr. KRATE supported the views of Mr. LANE, and made a motion to that effect.

Mr. FULLER moved that the clauses do stand as they are, which was carried.

Dr. Wilson then withdrew his notice of motion. In consequence of the proceedings at the last meeting he could not consent to bring forward any motion, and he took that opportunity of informing the governors that he had seen all his patients three times during the last week.

Mr. BABINGTON took up Dr. Wilson's motion, and it was carried.

Captain BAGNOLD moved that when a patient was attended by the assistant surgeon, his name should be placed on the bed card, as well as that of the surgeon.

The surgeons objected; motion with-drawn.

Mr. J. Lank now felt convinced that he could not carry a motion that stood in his name, and he therefore withdrew it. All the others but one (which was passed) were also withdrawn, and the meetings terminated.

Our reporter adds,—" Upon the whole these reports exhibit an instructive leason. They show how even a public institution may be rendered thoroughly subservient to the interests of a party. Such a result is not difficult of accomplishment in an esta-ination of the assaultable, while the patho-

on the voices of individuals whose title to vote may be supplied from the purses of the party who profit by holding office in the institution." The principles on which la for public hospitals should be founded, and which should alone be followed in the decision of questions of management, are wholly abandoned in the operation of such a system. Those principles are few and most simple. The first concerns the pattents,how their wants may be supplied. The second concerns the public,-how the science of medicine may be hest served as a means of promoting the public health. That these objects are the very last which have been considered by the party of Sir BEN-JAMIN BRODIE in legislating for St. George's Hospital, is so plain, that words would be wasted in a farther exposition of the fact.

FOREIGN MEDICINE.

Gazette Médicale de Paris, January, 1836.

THE four numbers of this journal for the month of January, 1836, contain so few original articles, that the whole are comprised in the following communication:—

1. Memoir on the False Membranes of the Cerebral Arachnoid, founded on Observations collected at *Bicitre*, by M. F. Le-LUT.

2. Memoir on Gangrene of the Lungs in Deranged Patients, by M. J. Guislain.

3. Clinical Reminiscences of St. Louis. Wounds of the Head, by J. F. MALGAINE, M.D.

FALSE MEMBRANES OF THE ARACHNOID.

The memoir of M. LELUT contains twelve observations of arachnitis in insane patients. accompanied by an exudation of false membrane. In all these cases the intellectual faculties were deranged in the most serious manner, and there was, in addition, some lesion of motility, consisting either in convulsions, agitation, or paralysis. The false membrane in all cases existed in the cavity of the arachnoid, like the false membrane in plcuritis or peritonitis; it was never formation between the arachnoid and pia mater, although Dr. ABERCROMBIE and several Sther writers speak of false membranes interposed between these two membranes. Indeed, many authors fall into this error. How many

isting outside that membrane!

The false membrane, in almost all the gases examined by M. LELUT, was situate on the convexity of the hemispheres, occupying the anterior part particularly: the author explains their mode of formation in the following manner. When simple serum is effused into the cavity of the arachnoid, it gives rise to the formation of false serous membranes, similar to those observed in true acute arachnitis. When, on the contrary, blood is exhaled in such a manner as not to produce a fatal apoplexy, the serous and aqueous parts are absorbed, and nothing is left but the fibrine, which is ultimately converted into a new tissue. · the

The authors who have observed false membranes on the aracknowd in a chronic form, are agreed in thinking that it is generally impossible to diagnosticate this lesion. Its symptoms are commonly confounded with those of cerebral compression or irritation, so frequent in maniacal patients.

GANGRENE OF THE LUNGS IN THE

The memoir of M. Guislain also refers to a condition sometimes observed in insane persons. LAENNEC describes gaugrene of the lung as a very rare disease; he saw it only six or eight times in the course of eighteen years' practice; M. Guislain has had occasion to see this disease much more frequently, in the insane patients at the hospital of Gand. He considers it as depending on the following conditions, viz., 1st. An aberration of the moral power consisting in a disgust and horror of all food. 2nd. A deterioration of the blood, in consequence. 3rd. An alteration of the pulmonary tissue, as a final result.

The attention of the author was first drawn to this disease by the circumstance of excessively foul breath in a patient, who for a long time had refused every kind of aliment. On examining the body he found the lungs extensively sphacelated. This obstinate refusal of food exists in many patients affected with melancholy; in one-ninth of all the insane, according to the author, it is excessively difficult to overcome; they sometimes rumain twenty, thirty, or sixty days without accepting any food, drinking ten days. Insane patients affected with this nething but some cold water, or fasting the disgust for food not only seem to be indiffe-

logical change is described as altogether ex- | first days of the week and then eating on the rest.

> M. GUISLAIN has made thirteen autopsies of deranged persons who thus died in a state of inanition: in nine of the thirteen he found the lungs gangrenous: in three cases the tissue of the lungs was of a darker colour than usual, and in one there was a simple congestion at the posterior part of the lungs. In the gangrene, one lung was always more affected than the other, and the lesion, which never implicated more than one-fifth of the lung, was more sensible at the summit than at the base. The patient never seemed to suffer any pain in the chest; he did not cough; the respiration was not difficult, nor was there any appearance of fever : the skin was cooler than natural, and the pulse rather retarded than accelerated. In all the insane patients who have abstained for any time from eating, the author observed a special symptom, viz., a change in the colour of the skin, always more striking the longer the patient remained without cating. This consisted in a brick-red colour of the cheeks, passing by degrees to brown or purple. It probably depends on a change in the composition of the blood, produced by abstinence. Inflammation of the stomach or abdominal viscera was not observed in a single case; the stomach always presented itself with the most healthy appearance. This is the more curious, as the experiments and observations of HALLER, DUMAS. BROUSSAIS, MAGENDIE, and ADELON, show that in most cases of forced abstinence the stomach affords traces of inflammation or even of erosion. In the insane person who refuses food, we find nothing of this; we see no trace of pain. When restored to his faculties, he affirms that he never felt hungry; we remark no fever, no heat of skin. no acceleration in the pulse. In abstinence of a healthy individual the force sinks rapidly; in the insane, on the contrary, the force is sustained nearly to the last day. He comes into the hospital after having fasted for 20, 30, or 40 days. He walks about, takes ordinary exercise, and continues to live in a state of extreme emaciation, though not much debilitated, for months, or even years, swallowing from time to time a mouthful of broth, while another person subjected to the same privations would die in eight or

rent to hunger, but the other seases appear | to the original papers contained in this exequally modified. Thus they support the sensation of cold and heat with an astonishing indifference; a heated iron applied to the skin produces scarcely any sign of suffering; they are indifferent to the loudest noises; they regard the sun without blinking, and all the other senses are in a similar degree of stupor. The following case, which we quote from the memoir of M. Guislain, shows that when the mental state has not made too great progress, we may hope to overcome the resistance of the patient, and even when the pulmonary lesion is very grave, an unexpected cure may take place:-

Case .- Marie de Leest, descended from a family in which several members were mad, was seized with a deep melancholy while in the establishment of the author. The patient was 28 years of age, of very delicate complexion, blue eyes, and light hair. months after her entrance she commenced to refuse all kinds of food; three days passed in perfect abstinence. Threats and entreaties were employed in vain. At length force was had recourse to, which succeeded twice; but the patient soon offered such violent resistance that the liquid was retained in the pharynx, and after some time rejected by the mouth. The introduction of a tube into the asophagus was impossible. The same fruitless efforts to introduce a little food were repeated day after day; sometimes, perhaps, a few spoonfuls of broth were passed. The colour of the face now commenced to assume the pathognomic character. The force declined gradually, and after two months spent in complete abstinence she commenced, without any previous cough or difficulty of respiration, to spit up fetid matter, at first rusty-coloured, and finally brown. At this time she did not eat a single morsel of food, as we were afraid to employ force lest suffocation should be produced. However, after remaining some time in this condition, she suddenly determined to eat, and in a few days the face recovered its former pale colour; the sanguineous fetid expecioration ceased by degrees, and the patient at length recovered a perfect state of health. She left the house in 1829, but came in again This time also her disease was in 1831. characterized by a refusal to eat, and by pulmonary disease, under which she sank. On opening the body, the left lung was found reduced to a dark and fetid mass.

Archives Générales de Midecine, September, October, November, December, 1835.

The press of other matter prevented us on a former occasion from noticing more than one or two articles contained in the last four numbers of the Archives Ginerales. We now return cellent journal for the last trimestre. They are.

1st. Researches on some of the causes that hasten or retard the period of puberty; by M. MARC D'ESPINE.

2. Conclusion of Researches on Dysen-

sery. By M. THOMAS.

3. Researches on the Pulse, the Respiration, and the Temperature of the Body in Discuses, and on the Relations existing between these Phenomena. By M. A. DONNE, Chef de Clinique.

4. On the Physiological and Essential Effects of the Rarefaction and Compression of the Air on the Body or Limbs. By M. T. JUNOD.

5. Memoir on Pericarditis. HACHE, Interne.

6. Clinical Researches into the Diseases of Old Persons. By Messrs. HOURMANN and DE CHAMBRE.

7. Researches on the Movements of the Heart. By M. BLAC, Interne.

THE PULSE, RESPIRATION, AND HEAT.

We present our readers with the paper by M. Donne, on the relations which exist between the pulse, respiration, and animal heat, in different diseases.

The experiments which form the basis of this memoir, were conducted at the hospitals of La Pitic and La Charite, with the object of determining how far the pulse, the respiration, and the heat of the body, are affected simultaneously or independently in several diseases. For a statement of the numbers ascertained during the great series of experiments made by M. Donne, we must refer to his memoir. Our space will only permit us to notice some of the general results which have been obtained. The experiments were made on persons affected with pneumenia, pleuritis, phthisis, hypertrophy of the heart, hemoptysis, chlorosis, diabetes, puerperal fever, hemiplegia, hysteria, jaundice, &c.

The first question examined was, in what diseases do we find the pulse most frequent, and the animal heat most elevated? The following numbers, selected from amongst a great many experiments, answer this first question:-

	Pulso, rather.	nespira
Hypertrophy of the [150 . 394 .	. 34,
heart	168 . 40 .	. 48
Phthisis	140 39	. 62
Typhus fover	Mind or and	

pulse and heat had attained the highest degree of elevation; the latter was measured By the centigrade thermometer, thirty-six to thirty-seven degrees of which give the normal temperature of the human body. It may be seen, from the above table, that the acceleration of pulse was always accompanied by an classition of temperature; the skin is most warm in those individuals in whom the pulse is quickest; this rule, however, cannot be generalized too extensively; it is not true in all diseases. Thus M. DONNE gives forty-two experiments made on patients affected with pulmonary tubercles; in twenty-six we do not find any relation between the temperature and pulse; in sixteen cases only, the animal heat fell or rose in proportion to the slowness or acceleration of the pulse. Again, in ten observations made on pleuritic patients, we cannot discover any relation between the state of the pulse and the degree of heat; on the contrary, in seven experiments made in pneumonia, the heat constantly rose with the pulse. The same relation was observed in twelve experiments on patients affected with hypertrophy; in eleven experiments on puerperal fever; in four experiments on jaundice; in six experiments on acute rheumatism; in five experiments on inflammatory fever; and, finally, in six experiments on typhus fever. In fourteen experiments made on females affected with chlorosis, the relation of the pulse and heat was by no means constant.

The above numbers confirm, in an exact manner, an opinion generally received amongst physiologists, although it never before was proved by direct experiments on a large scale-viz. that the animal heat often ascends or descends with the pulse. They also prove another point, which is contrary to the ideas generally received. They show that in some cases there is no proportion whatever between the number of pulsations and the degree of heat, although the relation of ascending and descending may still exist Thus, in one case of typhus fever, the pulse being at minety, the thermometer marked thirty-nine degrees; and in another where the pulse was up to 108 it marked 40°, the mesimum of heat in the human hody. M. Downe, however, remarks, that typhus fever is the only disease in which he observed this great disproportion between the pulse

The above cases were those in which the | and heat. In the normal state of the body, we do not find this close connection between the pulse and animal heat: this is easily proved by experiments, which every one can perform on himself; we can make the pulse mount fifteen or twenty beats in the minute, without producing the least change in the temperature of the body. In cases of disease this is not the case; the heat is elevated with the quickness of the pulse; but here an interesting question, which has never been examined by physicians, presents itself. Does this relation between the pulse and heat exist more in one disease than in another? Is it influenced by the nature of the disease? Thus, for example, does it depend on the integrity of the organs of sanguification, of the nervous system, or of any other apparatus?

> These questions are resolved by the tables given by M. DONNE. Thus, in tubercular affection of the lungs, and in pleurisy, the relation between the pulse and heat is more frequently absent than present. In chlorosis, again, we do not observe this relation; the latter disease, indeed, does not belong to the pulmonary organs, but sanguification may be regarded as imperfectly performed. In organic affections of the heart, such as hypertrophy, contraction of its valvular openings, &c. the relation is not constant, but it is more frequently present than absent. On the other hand, in puerperal fever, in hemiplegia, jaundice, inflammatory fever, ague, and peritonitis, the relation between the pulse and heat was almost constantly observed. In the theory of animal heat, such as it is generally admitted at the present day, after the researches of MM. Drione and DESPRET, the augmentation of the animal heat may be attributed to the acceleration of the circulation. In this theory, ninetenths of the heat in animal bodies is attributed to the combination of the carbon of the blood with the oxygen of the air, and hence the more quickly the blood passes through the lungs, the more carbonic soid will be formed, and the more the heat of the body is clevated. However, some strong objections may be made to this theory. In the first place, it is remarkable that one of the diseases in which the animal heat is most elevated, is precisely that in which sanguincation is most imperfectly performed : thus. in pulmonary consumption, the heat of the body often rises to 38°, 39°, or 40°, even.

where one half or two-thirds of the lungs are indurated, and impermeable to air. Again, the experiments made in tylhus fever, show that the animal heat depends on other sources than sanguification and assimilation; in that affection, certainly the pulse is not always much accelerated, nor the respiration very quick, yet we find the heat of the body mounting in one case to 39°, with a pulse of 93; in a second case, equally to 39°, while the pulse was at 108, and the respiration at 28.

M. Donne proposes to follow up these interesting inquiries. We shall take care to communicate his observations as they appear.

PERICARDITIS. •

The memoir on pericarditis, by M. HACHE, is an excellent resumé of the present state of our knowledge on pericarditis, by an old interne of M. Louis. The conclusions to which he comes are based upon eight cases of pericarditis, observed with all the care peculiar to the pupils of M. Louis's school; of eight more cases, collected by M. Louis between 1830 and 1833; and, finally, on an examination of these original observations with those published very lately by Professor Boulliaud of La Charité. It is not our intention to go over details already sufficiently known to the profession, we shall therefore merely notice a few principal points in the memoir of M. HACHE.

The cases observed by our author may be distinguished into two kinds; one where the disease was simple; the other in which the pericarditis was accompanied by various complications. In the first of these forms the disease appeared in such a manner, that if we were to be guided by the description given in any of our standard medical treatises, it would be impossible to detect, or even to suspect, the existence of inflammation of the pericardium. Thus the premonitory symptoms were mild, consisting in some pain in the precordial region, a little cough, and very slight fever, which did not prevent the patients from pursuing their ordinary occupations, or even laborious employment. After one or two weeks they came to the hospital on foot. Nothing in the patient's countenance of a general bearing, indicated the existence of a severe malady; the face was calm; the skin quite cool; the pulse moderate, and, we again repeat, without the assistance of percussion and auscultation, it would have been quite

tom much more frequently existing than authors generally describe it to be. Thus in all the cases observed by M. HACHE, the development of pericarditis was marked by some pain, at times slight, near the left mam-ma. The same result is obtained by examining the twenty-two cases detailed by M. Louis and M. Bouillaud, while in a moiety only of those published previously to the memoir of M. Louis in 1826, the presence of pain about the precordial region is mentioned. Palpitation is another symptom which frequently attends pericarditis. It is, indeed, mentioned by all writers, but it may not be uscless to give, what we may call, some statistical notes of this symptom. It was present in all the eight cases of M. HACHE. In the twelve cases of pericarditis published by M. Lours, it is mentioned six times. Thus we have palpitations existing in fourteen out of twenty cases. However, if we analyze the twenty-eight cases published by M. BOUILLAUD, we find palpitations mentioned only three times. How is this great difference to be explained? In many cases of pericarditis, the palpitations do not cause much distress, or attract the patient's attention, and we think with M. Louis, that if palpitations are not mentioned by M. BOULLAUD in more than three cases out of twenty-eight, it is because his attention was not directed to that point. This circumstance shows the necessity of noticing, as well those symptoms which are absent as those which are present, if we desire a case to possess the full value of which it is capable. It is a point upon which M. Louis insists with some carnestness, and is one of which English writers are by far too negligent.

The rational signs of pericarditis are, as we have before said, insufficient to demonstrate the existence of this disease: fortunately the physical signs are much more certain; they are given at length, and with clearness, by M. HACHE. Before entering on an examination of these signs, we should mention that the author seems to refer constantly to cases of pericarditis with abundant effusion, and not to the dry variety of Dr. STOKES. One of the first physical symptoms worthy of notice is a prominence over the precordial region, depending evidently on protrusion of the soft thoracic parietes by the distended pericardium; this symptom was very well marked in five of M. HACHE's cases. In one it was slight; in two young girls it could not be determined; but there the disease was very slight, and if a small difference existed between the two sides of the chest, it was masked by the volume of the brensts.

repeat, without the assistance of percussion and auscultation, it would have been quite cussion gave a dull sound over the whole of impossible to detect the change which had the precordial region, and above this, slong

the sternum, as far as the third, second, or fresh effusion. Four days after this relapse even first rib. As resolution took place, this the bruit de frottement reappeared, but with region became sonorous from above downwards, but in many subjects the sound remained obscure beyond its usual limits, at the time they left the hospital, all other symptoms having completely disappeared.

Auscultation .- In all cases the respiratory sound was absent, or more or less weakened. in the whole of the space occupied by the distended perleardium. This symptom evidently depends on the portion of the left lung which commonly covers the heart, being pushed on one side. As the effusion was taken up, the respiratory bruit re-appeared, from above downwards, in the space where it was before absent.

Sounds of the Heart.—In cases of effusion, the normal sounds of the heart are obscured and displaced; being more evident at the level of the third rib than elsewhere. The rythmus was altered in three cases only, and then in a cursory degree. M. Louis observed the same irregularity in two cases out of eight; and in fourteen cases of cure, reported by M. BOUILLAUD, we notice it only once. Hence irregularity in the pulsations of the hear exists only in one-fifth of cases of cure, and that in a mo-

mentary manner. It cannot be regarded as an important character in the diagnosis of simple pericarditis; it seems to belong rather to that acute and complicated affection of which pericarditis forms only an element.

Abnormal Sounds .- The bruit de frottement existed in only three out of the eight cases observed by the author; in eight cases reported by M. Louis the same bruit was absent; however, it must be remarked, that at the time the patients were examined, the pericardium was the scat of more or less abundant effusion. The three cases in which the bruit de frottement was heard, occurred in subjects who laboured under the disease for a great length of time, and it appeared at a period (23rd to 25th day) when the symptoms evidently showed that absorption of the effused fluid had taken place in part. In two cases this bruit continued only three days, was not very distinct, but superficial, and was not accompanied by vibration of the thoracic parietes. In the third case the bruit de frottement was very strong, and at its commencement presented the timbre of a sonorous bruit de cuir. During the last four days it was attended by a vibratory thrilling of the thoracic parietes, circumscribed, at first, like the bruit de frottement, to he portion of the third intercostal space that joins the sternum at the left side, it then extended to the whole precordial region, and disappeared gradually with the rubbing sound. The latter bruit ceased suddenly on the 12th day after its operation, when the increased prominence over the precordial region, and matity, announced a his own account.

less force, and was attended by no vibrating thrill. M. Hache says,

"These details confirm fully the result of the observations published by Dr. STOKES in the Dublin Journal, on the mode of apposition and formation of the fremissement vibratoire. It is developed under the same circumstances as the bruit de frottement, but much more rarely. In the cases reported by M. Bouillaud it is noticed only once, and then described as a new species of fremissement cataire.

"Thus, in thirteen cases of pericarditis, where the bruit de frottement was distinct, the fremissement was only observed twice, or in one-sixth of the cases; but as the bruit de frottement itself exists in only half the number of cases, it follows that the phenomenon discovered by Dr. STOKES exists only once in twelve cases, and must, therefore, be of secondary importance." case the author observed the metallic tinkling at a time when the effused fluid was nearly absorbed; M. Boulland has noticed the same sound in several of his cases. We do not propose to follow the author through the analysis which he gives of other symptoms furnished by lesions of innervation, of circulation, or nutrition; let us,

* We have given the very words of M. HACHE, or nearly so. It is evident that he has not read the paper of Dr. Stokes, or has heen led into error by an imperfect translation. In the first place, the object of Dr. STOKES's paper was not to prove the existence of fremissement as a diagnostic sign of pericarditis, but to direct our attention to the value of stethoscopic phenomena, and chiefly to the bruit de frottement, in the diagnosis of pericarditis. Again, Dr. STOKES does not describe the vibratory thrill as existing in all his six cases; and, finally M. HACHE'S statistics are evidently erroneous when he says, " in thirteen cases where the bruit de frottement, or de cuir neuf, was observed, the fremissement was perceived only twice," because a few lines before this he quotes Dr. STOKES's authority for six cases, in which these two symptoms coincided together.

Since writing the above observations, we have referred to the number of the Archives Ginérales (for January 1834), in which Dr. STOKES's paper is translated, and we must say, in justice to that excellent journal, that the translation is perfectly correct, and that the errors of M. HACHE must be placed to

however, my a few words on one symp- works of ANDRAL, LOUIS, and BOULLAUD. pericarditie; this is fainting: it was obwas complicated by other grave affections: pericarditis. Fainting, then, does not belong all cases, a moderate antiphlogistic method to pericarditis, and may, ia all probability, was employed with success. Digitalis was be attributed rather to the dangerous com-plications which exist in all cases where this of from six to thirty days, one grain the phenomenon manifests itself.

Diagnosis.- In the cases observed by M. HACHE, the pain about the precordium, palpitations with or without dyspnara, troubled dreams, or sudden awaking with fright, were nearly constant symptoms; but these are not sufficient to determine in a certain manner the existence of this disease, which can only be discovered by exploration of the chest. Then the development of the left side of the chest, the dulness of sound over the whole precordial region, with absence of the respiratory sound in that space, the displacement of the sounds of the heart, frequently attended with absence of impulse,-all these signs indicate the presence of effusion into the pericardium, and are the more important, because in most cases inflammation of that membrane determines offusion, and we are rarely called upon to examine a patient in the first days of his disease. These observations apply only to pericarditis with effusion; the author has not had an opportunity of seeing what Dr. STOKES calls the dry variety.

The march and termination of simple pericarditis are usually favourable. The disease terminates by cure from about the lath to the 22ud day, under the influence of antiphilogistic treatment; however, this malady is more frequently complicated than simple: thus in five of the eight cases reported by M. HACHE, he observed the following complications; in one inflammation of the lungs; in two rheumatism; in two tobercles. The coincidence of rheumatism is regarded as very frequent by M. BOUILLAUD, who says "rheumatismal pericarditis is incomparably more frequent than any other species; it exists in about the half of all subjects affected with severe articular rhenmatism." This assertion is rather too general; in composing the cases reported by M. BOULLAUD, ANDRAL, Dr. STOKES, LOUIS, and M. HACHE, have a total of 72, and find that acute articular rheumatism existed only sixteen times, or less than one-fourth.

The age and sex have a certain influence in the frequency of pericarditis. Thus the oldest of M. HACHE's patients was 38 years

tom, which, if our memory does not deceive we find only six whose age passed 40, and us, is given as a frequent attendant upon the majority was below 20. Pericarding, then, is a mulady of young persons, that it is served in two cases only, where the disease much more frequent in the adult than in the child. Females are less subject to the disease one patient suffered under this symptom at than males. In 107 cases collected by M. the commencement of the disease; another Louis, we find 27 women, 80 men; and in felt faint whenever he attempted to sit the 36 observations of M. Bourllaup, we upright. The same phenomenon was observed only once by M. Lours, and once by cessary to enter into any details upoff the M. Boulland; sever in simple cases of treatment of this disease by M. Louis. In first day, carried gradually to six grains in twenty-four hours : in two cases it produced a manifest lowering of the pulse, but the other symptoms were not relieved in proportion, and the pulse soon rose again, although the medicine was continued for a length of time and in elevated doses.

THE LANCET.

London, Saturday, February 13, 1836.

NEVER was there a more favourable period than the present for promoting a little gentle agitation on the subject of medical reform. But although there is an overflowing catalogue of abuses which require to be demolished, yet there are questions standing apart for consideration, which are altogether unconnected with the misgovernment and malpractices of our medical colleges, corporations, and hospitals. points a great difference of opinion prevails, many contending that a liberal system of government would be injurious to the interests of the community, while others believe that if the self-perpetuating principles in the election of the rulers in our colleges were abolished, good government in medical matters would be the certain and speedy result.

There is one grievance, however, which, although it is itself the source of much heart-burning and injustice, does not owe its origin to any enactments of the Legislaof age : of fifty-five cases contained in the ture, or to any charters granted by the Crown,

We refer to the unjust treatment to which | medical man shall be devoted in aid of the liament with whom he or his brethren quiry; but where the Coroner is not a meners' Inquests, is founded on such a just latter case, is the whole proceeding. It is and immoveable basis, that no danger can then nothing but a solemn farce, which is claim. What, we ask, is the value of the sion. inquest, in five cases out of ten, unless there | It may be alleged that witnesses are not be a medical witness present on the occa- ordinarily reimbursed in our Courts of jussion? And what right have the public to tice, except for the bare expenses which insist that the professional services of a are consequent on their attendance. The

In fact, the entire entrest our professional brothren to use their proceeding, in many instances, constitutes utmost endeavours to obtain support for a a worthless, nay, even a mischievous farce, bill which, in all probability, will be placed in consequence, almost entirely, of the en the table of the House of Commons on want of a law which authorizes the coroner the 2nd of March next. The mode of pro- to direct the payment of a sufficient sum for ceeding in that as in every other case in medical attendance. Be it observed, too, which the interference of Parliament is that a medical witness, on being summoned required, is by petition; but we would to attend at the inquest, is liable to be comremark here, that it is a great mistake mitted to a jail, in contempt of the mandate to suppose that one petition, however nu- of the Court, if he omit to be present at merously signed, is, or can be, equal in in- the inquiry. Ought such a state of the fluence to a great number of petitions; law to last? Is it possible that it can last coming from various cities, towns, and much longer if the medical profession disother places in the country; because in charge their duty to themselves and the the latter case a numerous body of public? This is a public and not merely a members of both houses of Parliament professional question. The welfare of the will be enlisted on the side of the profes- community is the point at issue. Often as sion. If there he but one petition, it can be we have thought and stated that the Court presented by but one member. If there he which is held by the Coroner, is one of the numerous petitions, they are necessarily most important institutions in the kingdom, placed in the hands of many members, who never has it struck us as being so vitally are then made to feel an interest in the sub- momentons as when we have reflected on ject, which could not from any other cir-the great value of the efficient and honourcounstance occupy their minds. Besides, able medical testimony of witnesses who each petition may ensure an application by have been educated in the science of mediletter, or a personal interview, or, at any cine. Even if the Coroner were himself a rate, some communication between a medi-| medical practitioner, it should be recolcal practitioner and some member of Par- lected that he is not a witness in the inmay be acquainted. Had we anything to dical practitioner, as we have a thousand fear from an investigation of the subject, times alleged he ought to be, in one half of we might be chary and cautious in hazard- the inquests that are held the money which ing such applications, but the demand of is paid out of the county rates for the exmedical witnesses to be paid for the time penses of the Court, might as well be tossed and services required in attending at Coro- into a river. Preposterous indeed, in this arise from its discussion,-none from the calculated to lull unreflecting and ungifted severest scrutiny into the correctness of the spectators into a state of pernicious delu-

parallel, however, does not held when it is attempted to be drawn between such persons and medical practitioners who give evidence at Coroners' Inquests. In the one case the witness generally attends because he was accidentally cognisant of the facts on which he is to be examined. In the other case the witness attends officially, and the value of his testimony depends on the time and money he may have devoted, in order to acquire a scientific knowledge of his profession.

Again. Without such testimony, the inquest is useless to the public. And, vet further, the entire duty of this attendance is necessarily restricted throughout a whole district, to the few practitioners who may be resident within its circle. Upon a very few persons the toil and responsibility of attendance on these occasions imperatively devolve. Upon what principle of justice, therefore, can a very few gentlemen, who have expended many years of their time. and many hundreds of pounds of their capital, in the mere attempt to render themselves competent to execute the general duties of their profession, be required to make. -systematically and regularly make,-the heavy sacrifices which the summonses of the Coroner usually demand? On our side of the question the entire justice of the arguments rest. On the other side of the question,-if there be an opponent,-he can be armed only with the weapons of prejudice. In the face of such instrument, the advocates of a correct principle stand in no danger.

But we must not remain passive and quiet in this emergency. It were folly, indeed, to continue gazing, stupidly gazing, at the progress of events, without taking some pains to turn the current of improvement to our own and the general advantage. All. that is, every friend to the cause of medical justice, should resolve to take part in the struggle. No doubt can be entertained of the successful progress of the Medical Witnesses Bill through Parliament, if

medical practitioners will but use their influence in sending petitions, start politions, to members of both Houses of the Light-ture, praying that such a, measure may be enacted into a law. We say to members of both Houses of the Legislature, because it is of the utmost consequence that an impression which is produced in one House of Assembly should not experience a countervailing check in the other.

It should be understood, also, that it is not necessary that the petitions should be written on parchment, as a sheet of common writing-paper is amply sufficient for the purpose.

Beyond praying for such remuneration as the Houses of Parliament may consider it wise and just to grant, it will only be necessary to point out the hardships to which medical practitioners are subjected by their being so often required to attend at inquests which are held many miles distant from their places of residence, occupying many hours of their time in the journey and in waiting during the progress of the proceedings. The folly, also, of drawing money from the county fund for the payment of the expenses of an inquest when efficient medical testimony is not received, should be shown, and allusion may with propriety be made to the necessity of instituting post-mortem examinations for the information of the coroner and jury, and of the danger to life which often attends such investigations.

And now let us hope that this grievance will no longer exist from want of applications for redress, or indisposition on the part of the Legislature to grant what is so truly and unquestionably just. Let us hope that a wiser state of things will arise out of the simultaneous exertions of the medical practitioners of this empire. Let it especially be remembered that no good result can follow any efforts which may be made, unless both houses of Parliament become the points towards which every effort is directed. Finally, we conjure every surgeon who may

this the greatest metropolis of the world. You have shone with equal brilliance in the Court and in the College. The polish and suavity of your manners have rendered you as acceptable at the banquets of great peers, as at the tables of commoners; and, as I have heard you yourself so justly observe, your presence at the hospitable board of our beloved Sovereign has absolutely conferred a distinction on the College, and is an honour to the profession generally. Now let me contrast with this, your true and just character, that of the ephemeral reptile, the mushroom, the mock surgical reformer. In place of the classical and moral education which you received at Oxford, and the elegance of manners and ideas which you there acquired, he spent all his time within the precincts of an Institution, where, instead of being occupied in those pursuits which expand the mind and ripen the understanding, he was employed as the dirty drudge of the Hunterian robber, whose -Alas! we are all creatures of dependent men.

attention to this subject. It is for you to

SPRING RICE, pray fail not to tell me the friars? Who will come forward with fiftyresults. It is better that I should communimay be committed in the proceeding.

" My DEAR SIR, -Our matters regarding cured an interview with Mr. SPRING RICE. with whom he assumed the character of a liberal, he got the Chancellor, step by step, to consent to see me. I soon found out, however, at my interview, that we had little to expect from Mr. Ricz.

"I began with explaining to him how carnest our College was to reform itself, and I assured him that in the course of one or two years the thing would be done satisfactorily to all parties. I explained to him that one great difficulty which we had to surmount was now got over by the deaths of TUTHILL and MATON, whose bigoted and contracted minds would not a to listen to any plan of reform, and that the few superannuated old downgers who remained in the College would, to the course of nature, soon leave this world of sorrow, and thus would enable us younger Fellows, to sweep away those abuses which are so loudly complained of. I must confess that all I said seemed to make little impression on the mind of the CHANCELLOR. I could distinctly perceive that our foes had been there before us, and that it is determined to overthrow the present medical corporate bodies. He evidently saw the motives which had influenced BRODIE, and CHAMBERS was much too thick-headed a fellow to alter his habit, and most of us are more prone to views. In fact, it now appears to me next to follow the path of evil than of good,-to certain, that a metropolitan university will become the leader of a set of corruptionists | be established, on the broadest possible basis, than the peaceful advisers of liberal and in- granting degrees in medicine and surgery on such terms as will best ensure to the "I have thought it proper to draw your public competent medical men, and permitting those who may obtain such degrees consider what reliance should be placed on to practise their profession freely, without those who now ostensibly co-operate with molestation, in all parts of the Pritish domi-you in your arduous endeavours to obstruct nion. " Thursday."

Sin, -I beg leave to offer my mite towards the general fund of plans concerning this important and humane question.

1. The parish officers should submit to view, in a public place or at an open vestry, a list including every pauper in the parish who cannot afford to pay for medical aid in case of sickness. The list to include every individual member of a pauper's family who is unable to gain a livelihood.

2. Every pauper or indigent labourer who claims a place on the medical list, to have his claims openly heard and discussed once a-year by the parish officers and the pa-

rishioners who pay the taxes.

- 3. After having made the list, the parish should agree with a medical officer to attend every person named in the said list, in case of sickness, for one year, at some fixed price, say fourteenpence per head in the country, and tempence per head in the town. If we consider that poor families are generally very numerous, about fourteenpeace will come near the mark; and if midwifery be included in the agreement, an additional sixpence should be added to each name on the list.
- 4. The medical candidate should be proposed by the guardians or the parish officers, and be elected by ballot, by those only who are on the list of paupers; by which means the paupers would be less liable to the abuses of a bad election. The paupers, doctor's complacency and attention, as the voters have on members of Parliament.
- 5. Should sickness occur to persons not named in the list, yet who are unable to pay for medical attendance, such cases to be considered as common cases, not belongdozen more names on the list.

Supposing a parish to contain fifty panpers who receive a weekly allowance, pro-We taken at 1s. 2d. per head, the sum would little enough.

This rate of payment is but very moderate, but then the practitioner does not expect to fatten by means of poor patients. Although the poor form an important part with you in the opinion that medical men

in the chain of society, yet the practitioner's principal reliance must be placed on the increase of his connections and usefulness through their means. The foregoing plan seems to me to be as simple and just as the nature of the circumstances concerned will allow; requiring, indeed, several modifications as to a fixed salary, &c. I am, Sir, yours respectfully.

Corwen, Feb. 8, 1836.

CORVINGE.

MEDICAL ATTENDANCE ON THE

SICK POOR.

To the Editor of THE LANCET.

Sin .- So much has been said in THE LANCET on the mode of procuring medical attendance for the sick poor, and the remuneration of the practitioner, and it has been said so well, that little remains to be usefully offered. However, a few observations on the subject may not be superfluous. At the same time I take the opportunity of congratulating the profession on the prospect of the whole mass of absurdities which constitute the laws for regulating (!) medical practice, being brought before Parliament through the medium of the Editor of THE LANCET.

The medical clauses in the Poor-Law Amendment Act in no respect contemplate an increase in the effectiveness of the medical profession, and the preservation of the health and lives of the poor.

Even if I approved of the mode on which also, would thus have some claim on their medical men are elected as attendants on the sick poor, I could find numerous errors in the details, but this would be useless, as I object in toto to the principle of contractto the letting out of medical services to hire for a specified period of time, at all hazards, "come weal come woe." Moreover, it is not ing to the agreement, and to be paid for honest to either party, as it implies in each extra, accordingly, by the parish. This a feeling of distrust. On these grounds I extra payment will meet the miserly design and my predecessors have at all times reof not placing on the list several who may fused to be parties to all medical contracts, have a just claim to be there. One such and consequently for years have not attended ease would prove the wisdom of placing a any "parishes." Of course also we have declined any participation in the plan under the new Act, which therefore does not in any way affect my interests. I have thus, hably there will be two hundred entitled to too, avoided the numerous disagreeable cirhave a place on the medical list. If these curustances which are so frequently complained of in parish medical competition, mount to 111 13s. 4d.; and if 6d. towards from the cagerness with which medical men bidwifery be added, it would amount to have caught at the depreciating offers of 161. 13s. 4d, which in a country practice is contracting overseers, jostling and jockeying each other in the scramble. Indeed, the present degradation of the profession scems to be self-sought and self-invited.

I do, therefore, on every ground agree

must rely only on themselves and the legislature for redress ginder the numerous evils arising from the freesent anomalous and unjust laws. As for the poor! may God help them. If the Malthusian doctrine be good, commend them to the tender mercies of enlightened commissioners, who confide them to the care of "American" practitioners, zens "catheter," zens "horse," sons everything.

Wire regard to renumeration, I think the following mode would be advantageous. In cases beyond a certain distance (a mile?) a mileage should be charged. For the case itself, whether in town or country, a charge should be made in the ratio of its duration,—a certain sum per day, gradually diminishing after the first three days. Thus for a continued chronic case there would be a smaller rate of pay, and in an acute case of shorter duration, when more time and trouble are bestowed, the rate of remuneration would be symewhat greater.

Under such arrangements the poor might apply to whom they pleased, each practitioner at certain periods giving in (as directed under the new Act) the names of those patients who have been under his care, with an account of the nature and duration of their disorders. I am, Sir, yours obediently.

A COUNTRY PRACTITIONER. Cirencester, Feb. 9, 1836.

POOR-LAW AMENDMENT ACT.

To the Editor of THE LANCET.

SIR, -The following statement will prove the hardship of my case under the Poorlaw Amendment Act. Three years ago I engaged in a practice of sixty years' standing, which comprised the medical attendance on five parishes in my immediate neighbourhood, but which five parishes will not give me sufficient interest to obtain the attendance on the poor in the district, in consequence of the sudden introduction of strange medical men by the Poor-law Commissioners. I shall not be able to retain even the one parish in which I reside. The consequence will be, the entire destruction of my practice, the committal of a dead robbery on my property, with the prospect of starvation to the sufferer. The Guardians, after allowing a certain sum for a certain number of attendants, should, at least, divide that sum amongst the established medical men, allowing them to remain undisturbed. I transmit you my name and address privately, and am, Sir, your obedient servant,

A SUFFOLK PRACTITIONER.

MEDICAL CORONERS.

To the Editor.—Sir, As predictive to be informed of the medical coroners tende the vicinity of the numerous readers of The Lancer, I beg leave to what state the footner for the county of Merioneth, is Enwarm Williams, Esq., of Bala, surgeon. In the next county to this, the county of Deubigh, there is also a medical coroner, R. Nigenda, Esq., surgeon, of Ruthin. Thus I would seem that we are wiser in Wales than they are in England,—two at least of its counties having chosen their coroner from among the members of the medical profession. I am, Sir, your obedient humble servant,

JOHN WILLIAMS.

Corwen, Feb. 8, 1836

Mr. SMITH'S INDENTURES .- To the Editor. Sir,-In answer to an inquiry made in the last number of your journal, by the author of the letter signed "INVESTIGATOR." I hasten to furnish him with a statement of the simple facts. About half an hour before my examination terminated, the Clerk of the Court gave me my indenture of apprenticeship, which I placed by my side, when the examiner who was sitting opposite to me, whose name I have not the pleasure of knowing, took it up and looked at it. The rest of the proceeding has already been made known. Now if this mode of proceeding be irregular, which the author of the letter in question considers it to be, I am only performing a proper duty in stating the facts, in order that a similar proceeding may be prevented in future. You will oblige me by inserting this note in the pages of your very excellent journal. I remain, Sir, your obedient servant, THOMAS SMITH.

1. Jewin-crescent.

To the Editor .- SIR. I beg to state, through the medium of your journal, that I have no knowledge or concern with certain individuals who have taken the liberty to affix my name to a preparation of Sarsayarilla, by printing it on the stamp,-as declared, at least, in certain advertisements. Nor have I, as I find it is asserted, anything to do with sarsaparilla, or any medicinal preparation whatsoever. Permit me also to state that legal measures will immediately be commenced in order to obtain redress for this most unjustifiable freedom, or forgery, as perhaps it might be designated. I am. Sir, most respectfully, your most obedient JUHN HANCOCK. servant, Commercial-road, Feb. 1836.

DERVISOSTREET HOSPITAL, DUBLIN. CLINICA REMARKS* SECONDARY SYPHILIS.

January, 1836 .- Ward No. 8. The case of this individual (Mary Ross) descrees your particular attention. She is, I presume, from her appearance, only seventeen or eighteen years of age. You observe she looks full, and in rude health. She, however, labours under secondary syphilis, and the manner in which she contracted the disease, as well as the form of her symptoms, should be known to you, and impressed upon your memory. First, as to the manner in which she contracted the disease: she affirms, and I am perfeetly convinced of her veracity, from the inquiries and examinations which I have made, that she contracted it from a child which she dry-nursed. Remember I have said dry-nursed. It is generally known that wel narses often contract a disease from suckling infants labouring under symptoms of syphilis; but I do not know that it is generally admitted, that the dry nurse may also, by the contact of such a child, become diseased. This is however the fact; here is a proof of it. Numberless are the analogous cases which I have seen. I have known the disease to be propagated through whole tamilies, yea, through a whole village, by simple contact. In all these cases, it is the matter of secondary sores which propagates the disease. You know that Mr. Hunter and his followers deny that secondary syphilitic sores are infectious or contagions. In this position they are quite mistaken. This is one of the numerous facts which my investigations have unfolded. The second point of attention in this girl's case, is the form of the symptoms. She has condylomata on the pudenda and round the anus, and you may here see that she has a fungoid excrescence on the surface of her tongue-You also remark that the front arches of her soft palate are ulcerated, and that the ulceration is of that superficial form which I have often told you almost uniformly accompanies condylomata. You also see that

Pr. Wallace gives clinical instruction in wo forms, by conversation at the bedside of the patient, during his walk through the hospital, and by lecture in the theatre of the hospital. The former are here called his "CLINICAL REMARKS," and to the latter we have prefixed the title of his "CLINICAL LECTURES. -Ed. L.

she has, scattered over her shoulders and arms, a number of some hat rounded spots, of a red-brown colour, very slightly raised, and scaly, scarcely larger than a split-pea. With these symptoms she had no pains, nor any affection of the fibrous, provial, or osseous systems. She has, in fact, the majority of those symptoms which you will find to occur in all the cases of syphilis which are produced by secondary matter. seen the child from whom she contracted the disease, and went to Fenglis for the purpose, and it labours under the same class of symptoms. I am anticipating by these remarks, gentlemen, some of a most important series of facts which I have discovered respecting the cause of the varieties in the symptoms of syphilis; and which I will very soon take an opportunity of communicating to you in a systematic form. The symptoms of syphilis under which this girl labours, yield with great rapidity to mercury, and are comparatively insensible to the action of the hydriodate of potash, which is, in some other forms of syphilis, a remedy far superior to mercury.

ULCERATED SURFACES.

February, 1836 .- Ward No. 4. See how admirably this man's case is advancing to a cure! Can anything illustrate in a clearer light the value of my mode of treating old ulcerated surfaces? He had lost, from slonghing and ulceration, consequent on an injury, a large portion of the integuments on the inner surface of his thigh; and an extensive ulcer remained, which he could not get healed. He says he had applied to many persons, and had tried in vain all the ordinary applications and methods. When he was admitted, the ulcer was not less than eight inches long and three wide; and the skin surrounding it was very indolent, or callous. You see it is not now more than five inches long, and in some parts scarcely half an inch wide, and the surrounding integuments are much softer and more natural. How has this great improvement been so rapidly produced? You have seen the treatment; he has been kept in bed, the surface of the granulations has been dressed with water-dressing : that is, lint dipped in tepid water has been daily applied to the sore, and then covered by oiled silk; and the skin surrounding the sore has been, to the extent of an inch, several times rubbed with the solid nitrate of silver, previously dipped in water. This application, you see, causes the separation of the cuticle, and a temporary exhalation, or sweating, from the surface of the cutis.

Let me explain to you the principles of this treatment. You will find, if you attend to the subject, that old chronic ulcerations are prevented from healing, much more by a morbid state of the tissues immediately surrounding, and under the diseased sur-

face, than by the stain of the diseased surface itself. Or, pendaps. it would be more correct to say, they they are prevented from healing, not only by the state of the discased surface Melf, but by the state of the surroundingsparts, upon the healthy action of which, me reparation of the ulcerated surfaces mainly depends. In the treatment of suchcases, however, practitioners seldom thinks, the surrounding parts. They apply dressings of various kinds to the surface itself, and seem to think nothing of the parts upon which the surface is placed, unless so far as they act on them by bandaging and by position.

My first object in the treatment of such cases is to leave the surface as much as possible undisturbed,—to let the regenerating The evening before her admission she ha lymph, when effused, remain without interruption; I do not allow the surface to be cleaned in such a way as to cause the slight-est friction. I avoid all stimulating applications, which, although they may be of the mildest kind, too often cause the destruction of the very weak granulating germs, and thus undo daily what nature in her attempts at reparation is endeavouring to the whole face; the left eyelid so puffed a accompuse. To carry my first object into effect there is no mode of dressing to be compared with the water dressing. laid on with great gentleness, and removed only when there is an accumulation of discharge. My second object is to excite and alter the morbid state of the parts, upon which the ulcerated surface is placed, and to this end I without or art on them with the witness of errysipelas has extended ever the loft care the witness of the parts. accomplish. To carry my first object into completely to obstruct her sight; pulse 110 stimulate, or act on, them with the nitrate of erysipelas has extended over the left car to stimulate, or act on, them with the nitrate of the occiput; pulse same as yesterday; howel silver, applied as you have seen it applied by opened by the medicine; great heat of skir Mr. Molloy in this case. By this method, and thirst; the catamenia have reappeared conjoined with an occasional purge, you will Two tablespoonfuls of a mixture, containin succeed in healing old sores, which can be one grain and a half of aconite and fou healed is much less likely to re-ulcerate than one healed in any other manuer. This I would explain by the fact that it is a mode a slight rigor about an hour ago. A mix of treatment which, by causing a healthy ture, containing one grain of the extract of belladonna in sixteen ounces of water, wa action in the surrounding parts, produces a now ordered, of which she took two table sounder cicatrix, and consequently one more spoonfuls every three hours. able to preserve its future integrity under | 6. DELIRIUM CUM BÉBILITATE -IMMENSE DOSES OF THE MURIATE OF MORPHIA.

Timothy Quill, aged 38, was admitted Dec. 18, under the care of Dr. Elliorson. He is an excavator, a strong and muscular man. He has been much addicted to drinking spirits, particularly rum, and has been considerably exposed to vicissitades of the weather, and to noxious effluvia, such as those arising from common sewers. On his admission he told a story about the origin of his illness six months ago, of its scat in the right side, and at the epigastrium; of his travelling to Ireland for the recovery of his health, and the return of the complaint on resuming his occupation; he complained of thirst, loss of sleep, and tenderness over the abdomen. These circumstances were related with perfect coherence of manner, but they turned out afterwards to be all entirely destitute of foundation. He was very restless during the night, often leaving his bed, putting on his clothes, wishing to go out of the hospital, accusing the other patients of robbing him, complaining of dinmess of sight and spectral appearances, and other mental delusions. A slight tremor, after careful observation, was detected in his fingers and his tongue. He says he has headache, and that he is thirsty. His bowels are confined, tongue clean, appetite very good. Pulse 60, slow and weak.

case of delicion dependent on debility; but over the olecranon; the bandage was therewithout the remarkable diagnostic sign of fore slackened; the man had passed a quiet that disease. He therefore ordered the night, patient, on the day after his admission, to have half a grain of the muriate of morphia directly, to be repeated at bed-time if separating over the triceps; copious effunecessary.

21. Rather more tranquil.

23. Sleeps better at night, but still labours under delusions, and occasionally talks and day; the bandages were removed, and a mutters loudly and incoherently, and is so violent as to require to be pinioned.

24. Is more tranquil and rational to-day. 26. He was extremely violent the whole of yesterday, and to day the irons have again been employed. Muriate of morphia, half a Liston and Dr. Quain, it was decided to grain, every fourth hour.

28. Was extremely violent the whole of test day. The morphia to be given every

three hours.

COMPOUND AND COMMINUTED PRACTURE OF THE OLECRANON .- FRACTURE OF THE THIGH .-- AMPUTATION OF THE ARM.

Charles Hussey, aged 36, a slater, was admitted October 15th, under the care of Mr. Cooper. He had fallen from a ladder, at the height of the third story of a house, in consequence of one of the steps breaking as he was ascending. The femur was broken transversely, at about the junction of the middle with its lower third. There was also a compound comminuted fracture of the olecranon of the left arm. With the point of the finger some fragments of bone could be felt within the wound, and one small piece was so loose, that it was taken out. The extremity of the olecranon was retracted by the triceps. The patient complained of pain in his side and back, where he had received some severe contusions. The thigh was put up with a long splint, in the straight position, and the elbow was extended by means of a splint in front of the joint, the arm having been previously bandaged from the fingers upwards. As a good deal of blood onzed from the wound, the sides of it were not brought together until the next day. A cold evaporating lotion was applied.

16. This morning a considerable swelling Dr. Errioman considered this to be a has extended up the limb, with ecchymosis

18. Not so well, has considerable fever; arm much swollen and discoloured; cuticle sion of serum in the cellular tissue up to the shoulder.

20. Mr. Cooper visited the patient toconsiderable quantity of pus, mixed with blood, allowed to escape from the wound. Mr. C. thought the man would have a better chance of living if the arm were amputated; but after a consultation with Mr. try to save the limb. Fomontations and poultices were ordered, and the arm was left free from all pressure.

30. Since the last report two or three abacesses have formed about the elbow, and been opened. During the last two days he has been exceedingly restless and delirious; his pulse has risen to 136. A grain of the muriate of morphia was given to him, and he was directed to by tept under the influ- erysipelatous swelling which has taken place

ence of that medical From this time the case got gradually worse; the pre-ent was delirious almost every night; he hand was cedematous, and erysipelas attacked the forearm and arm, near as high as the armpit, and matter was inffused under the integuments. The pydar was varying from 130 to 150. As soon, the swelling and redness of the soon, the swelling and request, Mr. upga arm had somewhat abated, Mr. form determined on removing the limb by the following operation:—An external flap was made, by introducing the point of a narrow smallish amputating knife into the centre of the posterior part of the limb until it touched the bone. The handle of the knife was then inclined towards the patient's side, and the point passed closely round the humerus, to the fore part. The external flap was then completed by carrying the knife through the biceps and centre of the front of the limb, and cutting down-wards and outwards. The flap was two inches and a half in length. The internal flap was formed by introducing the knife at late arrival, render it impossible for us to the upper and posterior angle of the wound, examine his statements with sufficient care and passing it round the bone to the front for notice in our present number. angle of the first wound, and cutting downwards. The fibres of the brachialis and the operation the pulse fell to 120.

Nov. 21. An incision was made into an printed "gentleman."

over the pectoral onseles; the inflamed skin had been bathed with the intrate of silver wash.

Dec. The patient went on favour. the stump coming to a an exceller; one, the thigh also having united.

HOUSE OF COMMONS.

Thursday, Feb. 4th .- Mr. WARLEY gave notice that on Tuesday, the lat of March, he should move for leave to bring in a bill to provide a sufficient payment to all legallyqualified medical practitioners who might be called on to attend, in a professional capacity, as witnesses at coroners' inquests. --Morning Chronicle, Feb. 5.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-

By M. ANDRAL,

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XII.

ATROPHY OF THE BRAIN AND SPINAL MARROW.

Gentlemen,—Having finished in our last lecture the study of hypertrophy of the nervous centres, we now proceed to examine the opposite state, or lesion, which consists in a diminution of nutrition,—in an atrophy of the same part. This atrophy of the nervous centres may result either from a primitive arrest or retardation of development, or from an actual diminution in the bulk and volume of some portion of the cerebro-spinal axis, after it has been fully and perfectly formed. Hence flows naturally a distinction of this disease into

Two Principal Species.

The first is congenital, rather an absence of formation than a wasting of the medullary substance when once developed. It has been described by several authors, and particularly by M. Cazauvielle (who has published an excellent memoir on the subject in the Archives Generales, t. 14), under the Jame of Agenesia, cerebral agencsy. The other form of the disease is not congenital; it occurs at a certain period after birth; it does not depend on original absence of the part, but is an acquired disease, produced by causes that we shall presently have occamion to investigate.

No. 651.

General Anatomical Characters.

Atrophy of the nervous centres, gentlemen, whether it be an acquired or a congenital malformation, may present itself to our observation under a great number of forms and degrees, from the slightest diminution in the normal volume, either of the totality or any one portion of the cerebro-spinal axis, up to the complete absence of all those parts together,—of the brain, the medulla oblongata, and its prolongation into the cavity of the vertebral canal. Between these two extreme cases we find an immense number of intermediate degrees, to the principal of which we shall presently recur in detail. No matter what may be the seat or degree of this atrophy of the nervous centres, the disease is recognised by a certain assemblage of anatomical characters, which we now proceed to lay before you. The gray substance enveloping the medullary pulp is more pale than natural. It very frequently retains its normal degree of consistence; but in some cases we find that the nervous substance has acquired an increased degree of density and consistence, at the same time that it has diminished in volume. The brain then appears more solid than usual; it has a harder pulp, and this is particularly the case when the atrophy attacks the convolutions or external layer of the cerebral mass.

The parts immediately surrounding the atrophied portions of the cerebro-spinal axis present sometimes certain lesions that we should not neglect to notice. These may affect either the membranes which envelop the brain and spinal marrow, or the osseous cavities enclosing the central mass of the nervous system.

When the Diminution of the Brain or Spinal Chord is very considerable,

the membranes take on an increased artion, and throw out a quantity of serum in proportion to the loss of substance which the nervous centres have suffered. In these cases we find a large quantity of serous fluid effused into the general cavity of the cranium, or into the ventricles of the brain and between its different convolutions, occupying and filling up the void that has been left by the atrophied beneather in the bones of the cree um. — sometimes the case, present a equal degree of atrophy, the when the skull, we may use the expression, follows the retreat of the brain, and is atrophy that exist in the brain. In some applied cloself on its surface, then the quantity of serry as much less considerable, and the member hes display a degree of activity in harman with the new object which they are cg and on to fulfil. It is not now the time to discuss where this serum is collected, for from what source it is more particu-larly derived. This question would lead us oo far from the subject of our present study; however, we may remark, that it would appear, from the researches which have been made by M. MAGENDIE, and at a still later period by M. le Docteur CAVARA, that it is accumulated in the cellular tissue which is interposed beneath the arachnoid membrane. In some cases the serum is not diffused throughout the surface of the brain, but is collected together in masses, contained of the absent nervous substance.

The Osseous Envelopes,

also present various changes, corresponding with the lesions of the soft parts beneath. and in this case the void left by the atrophied nervous matter is supplied by an effusion of erum, which we spoke of a short time back. When the disproportion between the cranium and the cerebral organ is great, the serum is found in large quantities; in other cases, the deficiency of nervous matter is made up by peculiar changes in the organization of the membranes themselves; the meninges are found much thicker than usual; they are incrusted with a cartilaginous or even an osseous layer, more or less thick, according to the degree of atrophy of the brain.

You may remark the analogy existing between this latter circumstance, and what takes place in other parts of the body. hus, when a portion of the lung has been lestroyed or atrophied, a lesion that frequently exists at the summit, in consequence of abscess, induration, and various other accidents, - when this, I say, occurs, and, at the same time, the thoracic parietes are unable to accommodate themselves to the altered form of the lung, to follow its atrophy by a corresponding degree of contraction, we frequently find osseous or cartilaginous matter thrown out between the ribs and surface of the lung, nature thus endeavouring to fulfil, by a morbid process, an indication which the state of the respective parts rendered impossible by a normal process.

did not present any alteration of form or ous diseases of the membranous envelope, as

of conformation, the different degree atrophy that exist in the brain. In some cases the bones are thicker than an ellormal condition, and yet this increased thickness of the skull is not appreciable on external examination, because the inner table alone is the seat of an increased nutrition. Here we have no default of development in the bones, corresponding with the want of development in the brain; but, in other cases, this is more marked. Thus, in a certain number of examples, the brain is more or less atrophied, and at the same time the osseous parietes sink down, and, as it were, follow the nervous substance in its retreat. The diminution of the cranium now alluded to may be partial or general, when the atrophy of the brain is general and complete; when the want of development in the osseous parietes of the skull is carried in one or more cysts, which supply the place to a very great degree, and is accompanied by a general absence of the brain; in a word, when we find no trace of nervous pulp where the brain should be, the malwhich protect the cerebro-spinal axis, may formation has received the name of anencephaly; this is the highest degree of cerebral atrophy. The volume of the head is Sometimes the osseous parietes are intact; reduced to the smallest dimensions, or, the form of the skull is perfectly normal, rather, no remnant of the cranium exists to show that its development had ever begun. However, we cannot now occupy ourselves with this lesion, which belongs more properly to the history of monstrosities.

In a certain number of cases, where the volume of the brain has been considerably diminished, or even the organ is completely wanting, the cranium, instead of following the diminution of the cerebral matter, retains its ordinary dimensions, or acquires an unusual volume, and becomes developed much beyond the normal standard. Here the bones are hypertrophied; they are more solid, more massive, more thick, than is natural; or, on the contrary, preserving their soft and membranous condition, they yield easily to the distending force of the serum which is shed between the membranes of the brain, and accommodate themselves to the increased bulk of the matters contained within their cavity. In this condition, the brain, and its osseous parietes, frequently attain a great volume, and are designated by the name of

Chronic Hydrocephalus.

We do not mean to assert, in an exclusive manner, that, in all cases of chapping hydrocephalus, the absence of the brain, and the development in the cranial case which accompanies this absence of the nervous mass, is always an effect of some ori-We have now alluded only to cases of ginal malformation in the brain; it may, atrophy in which the parietes of the skull and in fact does, sometimes depend on vari-

inflammation, increased socreting activity, tion of the next cc.; however tome cases, the atrophy of the permits substance, with increased bulk me head, does really depend on an original ower of nutrition.

Finally, in some cases that are not very unfrequent, the membranous parietes which supply the place of a hony envelope, open; the cerebral substance, unsupported by its usuals protecting boundaries, escapes from the cavity, and forms a

Cerebral Hernia

externally; or a membranous pouch fille lungs are absent, and the digestive tube with serum, and bearing more or less resemblance to a cyst, projects through the deficiency in the cranium.

In the lew observations which we have now laid before you, we have not attempted to give anything like a complete history of the different lesions observed in cases of anencephaly, of accephaly, or other malformations of the cerebral mass connected with atrophy. Our object has been merely to touch in a general manner on the relation which exists between these different states, and a default of development in the brain and its osseous parietes. They were also necessary to explain the numerous and considerable lesions which we sometimes observe in the parts, whether membranous or bony, that surround an imperfectly develoned brain. Let us now turn to a consideration of the

Causes of Atrophy of the Nervous Centres.

These are not always the same. Some of them depend upon the non-accomplishment of certain acts or formations that should have taken place during intra-uterine existence.

One of the most beautiful results of the researches which have been made within latter years to determine the mode of forma. tion of animal bodies is the discovery of this curious law, "that most of our organs pass through a series of successive revolutions, each of which represents a normal and permanent organization in inferior animals." The operation of this law is seen in the brain as well as in other organs. Hence at any period when the centre of the nervous system is not yet completely formed, and an arrest of development takes place, implicating either the whole organ or any particular portion of it, we may observe the different types of atrophy which we described a few moments ago, the lesion being more com-Pete as the developmental nisus is arrested a hore early period, and in different parts of the brain at the same time. Here then is the first cause of atrophy of the nervous centres; it consists simply in a modification of nutrition, in an arrest of the "nisus formativus;" but why this arrest should formativus;" but why this arrest should constituted; all the parts exist in a state of take place at one period of fetal life rather perfect integrity. We find the hemispheres, than another; why it should attack one por- the corpora striata, the central parts, such

tion of the next of utres, leaving others that are contemporane vely developed, intact; there are questions but we are unable to resolve. We can only a licate the arrest of development, without only able to mount beyond it. It is worth of remark that in fetures born with my or leave. that in fetures born with m or less atrophy of the nervous centre quently observe at the same tin deficiency of several other organs showing that the lesion of the brain really depended in an arrest of its development; thus the heart is formed in imitation of the batrachia; th presents more or less resemblance to the simple alimentary canal of lower animals. Again, imperfect development of the brain

may depend on various maladies of the membranes which envelop the nervous substance, and by which, according to some physiologists, the nervous pulp itself is accreted. We can understand readily how this may take place, by supposing that the membranes draw towards themselves an unusual share of nutrition, or by a too great activity of secretion prevent the development of the more solid parts. This latter is a powerful cause of arrest of development in several organs contained in the cavities of the chest and abdomen, and may certainly operate also in modifying the nutrition of the cerebral mass. When the absence of a normal degree of development depends upon some disease of th (brain, or on inflammation of the pia mater, or irri-tation of the collular tissue that every where supports the pulp, the brain may present a general change of form rather than an absence of any considerable portion of its substance. Thus in the latter set of cases alinded to, where the cavity of the cranium contains an unusual quantity of serous secretion, all the different parts, whose ensemble constitute the cerebral hemispheres, have been found to exist. The hemispheres are as it were unfolded; the convolutions are separated from one another and spread out into a vast layer of medullary tissue, resembling a membrane, but on close examination, we find that the nervous substance remains intact in the midst of changes apparently so profound. There is a modification of form only ; but no actual diminution, no atrophy of the mass. This has been frequently seen by Dr. CHASSAIG-NAC, who has paid particular attention to the changes that take place in the arrangement of the nervous substance during the progress of chronic hydrocephalus.

There is another Species of Atrophy

of the nervous centres which we must not neglect to mention. Here the brain is very small, very small indeed, but it is normally

mation e a single part

Wenave now touched upon a great order of sauses which produce atrophy of the ebral hemispheres, viz.. disease or irritaon of the membranes, and we are the more induced to admit the operation of this cause when we reflect that in a great number of cases the meninges are injected, thickened, contain abnormal deposits, and present more or less trace of antecedent disease.

Cerebral Atrophy from Accidental Productions in the Brain.

Certain atrophies of the nervous centres depend on a different order of causes. Thus suppose a tumour developed in the anterior of the skull: this must necessarily exercise a greater or less degree of mechanical compression; and the convolutions thus pressed upon, are sometimes completely removed, or at least reduced in bulk and volume. In other cases these accidental productions, instead of acting in a mechanical manner, seem to occasion atrophy of the cerebral substance by exciting a certain degree of irritation in the parts with which they are in contact. Hyperemia is the first result, and when once the nutritive nisus is deranged, a state of atrophy may succeed this deviation of nutrition, as well as a state of hypertrophy. This is a curious fact, though a certain one, that irritation gives rise to diminution of volume in the part which is the seat of ex-We have had occasion to obcitement. serve a remarkable case of this latter kind in the person of a man twenty eight years of age; who at the age of three fell on his head into the street from a first-story window. The accident was soon followed by paralysis on the left side of the body. The intellectual and other faculties, however, remained intact. This individual died of an inflammatory affection of the abdomen, and on examining the body after death we found that all the middle portions of both hemispheres situated above the lateral ventricles were completely gone; nothing remained of these parts except a vast cavity filled with limpid scrum. Here the lesion supervened on external violence giving rise at the commencement to irritation, probably inflammation of the membranes, and subsequently to extensive atrophy of the hemispheres.

Finally, various diseases of the brain may determine an atrophy of the nervous sub-

which surrounds an applectic cell may in all the componers portions of the brain, are found, but they tist as it were in miniature. The organ has tuffered from a general arrest of development, acting equally upon all parts, and string rise to an excessive smallness of the whole mass, without any matter. found much diminished in volume, and transformed into a species of serous cavity.

> We have now exposed at some length the anatomical characters of atrophy of the nervous centres. We have laid before you a history of the lesions observed in the osseous parietes, and in the membranes enclosing the brain. It remains for us only to add, that in some cases we are unable to discover any cause which has given rise to the diminution of volume in the brain. Here we may be permitted to ask, Is the default of nutrition connected with a want of due exercise of the intellectual faculties? muscle condemned to constant inaction wastes away. May it not be the same for the organs of intelligence? This is not improbable.

> The lesion which we have designated under the term "atrophy," does not present itself with the same frequency in all parts of the nervous centres. It becomes more rare as we pass from above downwards, from the surface of the brain to the more deep-seated parts; and it may be established as a general rule that it exists less frequently in those parts of the cerebrospinal axis which are first developed, than in the portions which arrive more slowly at their perfect degree of organization. Thus atrophy of the spinal marrow is more rare than atrophy of the brain, and, again, in the cavity of the cranium, the deep-seated parts, which are first formed, are less frequently

> which they have been specially observed. We shall follow their order of frequency, and trace their history, in the cerebral hemispheres; in the deep-seated parts; in the annular protuberance (pons); in the cerebellum; and, finally, in the spinal marrow. And first for

the seat of this lesion than the convolutions.

We now propose to pass in review the vari-

ous degrees of atrophy of the nervous cen-

tres according to the different points in

The Anatomy of Atrophy of the Cerebrum.

Here the lesion may present a great numher of degrees, from a slight diminution of the normal volume, to the complete disappearance of the organ Let us commercie with the most severe cases. A certain A ber of examples have been recorded" which the whole mass of the cerebrum was entirely wanting: there was no brain whatever: and in these cases it is at the stance immediately surrounding the affected same time proved that extra-uterine expart of the organ. Thus some observations istence is impossible; or at most possible seem to establish that the part of the brain only for a few short days. The unfortu-

nate beings subject to this degree of mallone or both hemis formation, seem made to live only in their here also the indimother's womb and as the arc remoted pendent castlence, incanable by their organization, of thinking these two cases from any single act of arimal life, so they are incapable or an independent existence, and after a few hours of vegetation lay aside life, which is incompatible with the absence of so large a portion of the nervous centres. This is the highest degree of atrophy of the brain. In place of that organ we find nothing but a slight trace of medullary lamellæ, which afterwards form the brain in a normal condition; or the nervous substance is supplied by a secretion of serous fluid, or by a mass of vasculo-cellular tissue, the rudiment of that membrane which is destined to surround and support the different parts of the interior of the brain. We have already spoken of the condition of the bones in this state; sometimes they are flattened down upon the base of the cranium; sometimes we do not find any trace of conformation of a skull; the parietes are membranous, and contain here and there irregular spots of ossification.

In other cases, as we have already mentioned, the destruction or absence of the cerebral mass is not indicated by any external symptoms. Thus BECLARD has cited the case of a child who lived five days; the ccanium was well formed, but it contained no brain; the whole of the cerebrum and cercbellam was absent, and their place supplied by a great quantity of serous fluid contained in the membranes; the spinal marrow however was not absent; this portion of the cerebro-spinal axis had attained its normal degree of development, and terminated superiorly in two bodies corresponding with the cerebral peduncles (crura cerebri), each of which again terminated in a kind of renflement, or swelling of the nervons substance; two small chords were observed detached from these bulbs, which ran forwards towards the ethnioid bone, became engaged in the groove of the ethmoidal plate, and, finally, terminated in an oblong swelling, exactly analogous to the balb of the olfactory nerves: here an arrest of development produced in man a disposition of the brain peculiar to certain animals, which, you know, are furnished with olfactory lobes placed in front of the cerebral ones, and destined solely for the production of a single pair of nerves, the olfactory.

The history of the symptoms connected with this form of cerebral atrophy is not one; indeed, it is unnecessary to enter on it. We have seen that this child is, from the instant of birth, condemned to a premature grave; it may enjoy an imperfect life for a few short days, but death is an inevitable consequence of this malformation.

Next, to complete absence of the whole atrophied. Here we have to consider the cerebral mass, we may arrange cases where lesion as it may occur in the anterior lobe,

one or both hemist eres are wanting, and here also the indicated is incapable of independent "Amelies. We must distinguish these two cases from these where, in consequence of imperfect development of the superior masses of the hemist eres, we might be led to imagine that the thain was wanting altogether. In the form an owallude to, there is an absence only to the parts which are situated above the full of the ventricles; when the malformations a trophy is thus confined, when the impirant parts comprised in the cerebral mass phicod beneath the level of the lateral ventricles are sufficiently developed, then a great faccomes to light—viz., the possibility of extrauterine existence. In

Alrophy of the Nervous Substance placed above the Level of the Lateral Ventricles,

we may observe two degrees. the atrophy exists at one side of the brain alone; in the second, it has implicated both hemispheres at the same time. Sometimes the whole of this superior portion of the brain is replaced by a membranous bag containing serous fluid; at others, the lateral ventricles are laid bare, and without any dissection we see the thalami corpora striata &c. This case, as we have already observed, does not necessarily compromise life; the individual may continue to live for several years, but all his faculties and senses are obtuse. many of them annihilated, and he lives in a state of vegetation rather than of humanity. When the absence of the substance is less considerable, and confined to one side of the brain, life, as you may conceive, is carried on more, much more, perfectly. This degree of atrophy has often been observed in persons arrived at an adult age. It is compatible with a perfect integrity of organic life, but the intellect is generally obtuse, dull, or idiotic. However, cases of an opposite kind have been seen, and it is remarkable to observe how the intellect may sometimes be conserved with a very great absence of the substance of the brain. M. BRESCHET has published a curious case relative to a child, four years old, where the intellectual faculties were much altered; the infant was plunged in a complete state of idiocy; but what we notice this fact for is to point out the occurrence of mutism. The child was dumb, although not deaf. In all the other cases observed, we do not find mention made of a similar phenomenon. Again, in a great majority of cases we have hemiplegia: the power of motion is lost in one side of the body, although the nervous mass lying below the level of the lateral ventricles exists in a perfect state of integrity.

We now pass to an examination of those more severe cases where the substance of the brain below the ventricles is more or less atrophed. Here we have to consider the leasion as it may occur in the anterior lobe.

in the middle, or in the esterior lobe. We much the more are we convinced of this in the middle, or in the seteror lobe. We may remark that the sperior lobes are wanting more frequently than eather of the two others, and his atrophy may affect either one of the anterior lobes alone or both together. When both anterior lobes are absent of their we generally find the cranium decrement at the same time it is flattened on in the forward part, and the foreshore the same less some Howards. flattened in in the forward part, and the foreless in more or less gone. However, some isses of the kind we now speak of, may kits with an excellent conformation of orehead. Here the cerebral mass which is secreting is supplied by a quantity of serous offusion, or by membranous cysts filled with a clear fluid. What are the symptoms that accompany this

Absence of the Anterior Cerebral Lobes?

How are the great functions affected? Is the intelligence modified? How far? What lesions of motility does it produce? These are questions that we must now cndeavour to resolve.

The intellectual faculties are generally modified in a considerable manner, or sometimes completely abolished. Thus M. BRES-CHET has recorded a case in the Repertoire d'Anatomie, of a girl, 15 years of age, in whom both anterior lobes of the brain were supplied by a membranous cyst, at the bottoin of, and behind which, the corpora striata were seen distinctly exposed. This child was a complete idiot; she could not clothe herself, required to be fed, and remained constantly in the same position without taking any notice of what passed around her. What symptoms do we observe in connection with movement? In some cases motility does not undergo any modification, although both the anterior lobes of the cerebrum are simultaneously wanting. This took place for example in the person of the idiot child just mentioned: her listlessness and constant rest did not depend on paralysis or feebleness of the muscular power, but on an absence of volition. The same phenomenon, viz., absence of paralysis may also be seen in two other cases published by M. BRESCHET: in other cases we observe nothing but a general feebleness of the limbs, and this gradually increases until the patient at length falls into a state of paralysis, being unable to move either his upper or lower extremities.

In one of M. BRESCHET'S cases there was an abolition of vision. The child, nineteen months old, was perfectly blind, yet we cannot see any connection between the anterior lobes of the brain and the faculty of vision. We cannot understand why an absence of these parts should bring with it complete cecity. The truth is, the more we see of diseases of the nervous system, the further we advance in the study of their history, the more knowledge we attain upon the complex point of medical science, and so shall, therefore, content ourselves with sim-

fact, that the different acts of the brain are connected to wher as interactly and as closely as are its different analogued parts by a continuity of organization; and so in. the more do we feel the secessity of studying in the nervous system, mst, as detailed acts, and secondly, its action of ensemble.

In another case of absence of the anterior lobes, we find loss of the sense of smelling : this phenomenon is readily explained, and need not arrest our attention. The olfactory nerves are attached to the anterior lobes. When the latter are wanting, it is quite natural to find an absence of the power of smelling. Now for the cases

Where only One Anterior Lobe is Absent,

the other presenting its normal degree of development. Here the brain does not seem to have any great influence on the intelligence; it is ordinarily developed in a moderate degree. The individuals, though not, perhaps, remarkable for talent &c., possess a common share of judgment, good sense, and knowledge of society. In some cases, however, the intellectual faculties are modified; the individual is far from being an idiot, but his mental power is evidently diminished; the intelligence is dull, slow, weaker than natural. In most of these cases of atrophy of a single lobe, we observe bemiplegia, and we draw the same deduction for these that we have done for cerebral hemorrhage, viz., that the paralysis almost constantly occupies the side of the hody opposite the injured hemisphere. In one case, which is recorded in the fifth volume of our Clinique, p. 620, the patient, a man, seventyone years of age, in addition to complete paralysis of the left side of the body, was affected with an extraordinary difficulty of speaking, or rather of articulating; he could only mutter a few unintelligible sounds. After death we found the anterior quarter of the left hemisphere replaced by a transparent cyst, containing a limpid serosity. This, you may remark, is in accordance with the observations of M. Boull LAUD, who attributes the power of co-ordinating language to the anterior lobes of the cerebrum. Examples of atrophy, or even of complete

Absence, of the Middle Lube,

below the ventricles, have also been observed. These cases were accompanied, like the former, with hemiplegia of the opposite side, and the intelligence presented the same modifications as those which we have just mentioned. The same remark applies atrophy of

The Poeterior Cerebral Lobe.

The symptoms do not differ in any point worth noticing from the former cases; we

ply mentioning the fact. In one case we and the patient observed an absence of the middle and nos- lesion of moveterior lobes of nemispirat the same time. ecurred in the erson of a man enty-eight years of age, whose case we lave already spoker of at the commencenent of the secture. The middle and poscrior lobes on the right side were comdetely gone; nothing remained but the nembranes floating in a clear liquid, and a portion of the anterior lobe situate in front if the corpus striatum. Here was absence if a very considerable portion of the cereral substance: yet, notwithstanding, the ndividual enjoyed a common share of inteligence; his memory was good; he spoke reely and easily. Up to the day of his leath he never presented any symptoms of lisorder of the mental faculties.

You are all acquainted with the position and form of a cavity which anatomists have alled the

Posterior Horn of the Ventricles.

Dr. HASTINGS has described two cases of trophy of this portion of the hemispheres: on will find them detailed in the 59th voume of the Bibliotheque Medicale. Cuvier ad established, that this posterior horn of he lateral ventricles is very much developd in the brain of man, while it is much maller, and sometimes quite a rudiment, in nferior animals. We are totally unacquaintd with the part it plays in the manifestation f such or such faculty; we shall only retark, as connected with Cuvian's obseration, that in the two cases alluded to, there xisted a lesion of the grand characteristic which distinguishes man from animals,-inelligence.

In all the cases of cerebral atrophy which we have hitherto passed in review, certain sarts of the hemispheres were absent; there was a real loss of substance: the hrain did not present the ensemble of all those parts chich constitute it in the normal state. But trophy may present itself under another oint of view. Here we do not find an accural absence of any part of the brain; there is a general

Diminution in the number of the Molecules of the Brain.

The brain is well formed, but much smaller han in the normal state. This diminution of volume, affecting the cerebral substance for volume, a free time to composite to that form the osseous parietes one, a single one, a portion of a lobe, or exist on both atter kind, published by Dr. Calmell, is, or haps, the most remarkable we have on ecord. (See Journal Hebdomadaire de Médeise, t. 1, p. 225.) All the parts composing the cerebral hemispheres were imperfectly leveloped, and equally so on both sides, site side of the body.

s epileptic. No other r intelligence existed. The interior of the lingence existen.

In it a fact worthy of your attention; it cannot fail recalling to aur minds what we said in an early part of oil course, where we showed that a variety of less us often coexist with the same symptom, with the nervous system is in question. Thus it aur last lecture we noticed a case of epilepsy, belued by induration of the cerebral substant. Here self as a consequence of atrophy; the organic lesions differ widely from one anoner; the functional symptom to which they g rise is the same. The form of atrophy of which we speak, may be circumscribed by a few convolutions; in that case we often find them hard and compact, and wrinkled on the surface like a cicatrix. Instead of the convolutions, the atrophy may occupy the more deep-scated parts, viz., the optic thalami, and the corpora striata. These two elevations may be either simply diminished in volume, without any change of structure, or the atrophy may engage more particularly the gray or the white substance which enters into their composition. In some cases we find not a diminution, but a complete

NTRES.

Absence of the Thalami and Corpora Striata.

They are replaced by a serons cyst, or we may simply observe their absence without finding anything in their place. When these bodies are simply diminished in volume, the hemispheres may or may not be wanting; but when the thalami and striated bodies are absent, we constantly find at the same time an absence of all the nervous substance placed above them. We find nothing but a membranous tissue, and a few scattered filaments. The brain represents the condition in which it existed at a very early period of fetal life; it represents the normal type of the cerebellum in a certain class of organized beings.

Atrophy of these parts, whether general or occupying only one side of the brain, has been observed at all

Periods of Life,

from infancy to the most advanced old age. Sometimes the cranium is depressed upon the portion of the brain seated beneath the absent parts. Here the lesion is discoverable during life, and we have a state exactly opposite to that form of hypertrophy where the osseous parietes seem to be pushed forwards by the development of the brain.

The different modifications of intelligence that we have already pointed out, have existed in individuals affected with atrophy of the thalami and corpora striata, and whenever the diminution of volume has been at all extensive, we have paralysis of the opposite side of the body.

The White are called they of status of the brain, as the various examples of atrophy. They may be diminished in youne or be absent, without any lesion of the rest of the hemispheres. In a few atrophy of the septum lucidum have in observed. In others the want of dever ment affects more particularly the corp 2 callosum, and this mass of cerebral me ker is reduced to the form of a fine memrane. Reit has left us a remarkable exfample of this latter kind, in the person of an idiot, thirty years of age, in whom the corpus callosum was completely gone, and the two hemispheres of the brain merely united by the anterior and posterior commissures. This is another example where an arrest of development in man gives rise to a form of structure that is peculiar to animals. Thus, in birds and reptiles neither the sentum lucidum nor the corpus callosum normally exists. You will also find some curious cases of atrophy of the central parts, detailed in the thesis of M. BOULANGER, No. 195, for the year 1821. In two of these cases there was complete absence of the corpus callosum, and in one the septum lucidum slso did not exist. The patients were both idiotic, and one was unable to walk, or sustain herself on her limbs.

Atrophy of the Pineal_Gland.

Before we conclude, let us say a word on atrophy of another part, whose use is not vet established, although it exists constantly in the four classes of vertebrated animals. The pineal gland presents a great number of variations in volume : in some cases it is excessively small, not larger than a grain of millet-secd. In others it is so far reduced, that we may in effect consider it as wanting. These varieties in the bulk of the pineal gland do not bring with them necessarily any modification of development in the other parts of the brain, and we are not aware that they are attended with any appreciable symptom. Some writers, indeed, have attempted to connect atrophy of the pincal gland with a diminution of the intellectual faculty, but this is a theory unsupported by a single fact, a supposition in which we can place no belief whatever. We the tube. The next day you find the instru-shall continue this subject in our next ment still looser, and the discharge more lecture.

CLINICA ECTURES ON CARRS OF

DISBASE OF THE URINARY ORGANS. Delivered in the Session of 1836.

BY MR. LISTON.

LECTURE II. (Concluded.)

Catheterism in Cases of Stricture.

Now I would have you follow, in these cases of bad stricture, the practice I have detailed, such practice as, in fact, we have pursued in the several cases I have brought in review before you. You should try to get an instrument into the bladder. It is all the same whether it be large or small. Tie it in; and it is better to begin with a metal catheter, such as this, at once, than to be poking away with these wax catheters, clastic bougies, and bits of fiddle-string. What can you expect by trying to put such a thing as that (it is called a catgut bougie, I think) into the bladder? It is better to work with an instrument with which you are sure to succeed. You are recommended by Sir Benjamin Brodie, a great authority in these matters, in this book of his, to try first all sorts of things, guin catheters, catgut bougles, et cetera; then you are to bend your bougle after this, that, and the other fashions, and if you fail not withstanding, you are at last to have recourse to the silver catheter. Why, the mischief, should you not take the silver catheter at once and pass it into the bladder?

Well, you introduce the catheter, and how does it act? Why, in the first place it is grasped and held firmly by the stricture, so that the patient or the surgeon would find very great difficulty in withdrawing it. But after a little time the parts become impatient at the presence of this foreign body. and a natural process is set up for its discharge. It is exactly the same process as that which takes place to favour the escape or ejection of a foreign body lodged in any part of the living tissues. There is a pro-fuse discharge from the surface of the urethra, and the parts all become widen and relaxed; and unless the catheter war tied in properly, it would tumble out in the course of twenty-four hours, part of t water comes to be discharged by the side of profuse. You then cut the tapes with which the catheter is tied, and can pass a larger one without any difficulty. Then allow the

THE KNIFE.

ply mentioning the fact. In one case we and the patient observed an absence of the middle and postlesion of moyas at all this while I canterior lobes and mention to see that commencement of the practice. After a time age is right, and then make the instrument ment into the bladder, and after that, in the instrument into the bladder, and after that, in much longer. Be set the end of four or five days, and thut proceed until you they went on passing instrument severy day, have brought the canal to its natural state. I would not have you retain these catheters longer than forty-eight hours, or three fering to the patient, and as not exceed a spreaduring great inconvenient and suffers at all events, otherwise a great deal way to restore the parts to their attural of mischief will arise. You find, if it is kent state—certainly not the way to restore the parts to their attural days at all events, otherwise a great deal of mischief will arise. You find, if it is kept in very long, that the further end of it, the eyes, become coated over with earthy matter, and, in withdrawing it, portions of that earthy matter have sometimes been separated, and a nucleus for a calculus has been formed in the bladder. Another mischief which I have seen to result occasionally, is the formation of abscess in the canal, and, frequently, anteriorly to the scrotum. A false passage is the consequence, and it is very difficult to get an opening in this part of the canal to heal up. It has been proposed in what are termed "impassable strictures." - but there are no strictures impassable, that I have seen, for when any water comes away, you can, by patience and perseverance, get a catheter through, sooner or later,-it has been proposed to introduce either an clastic gum catheter, as recommended by DUPUYTREN, or a silver catheter, down to the stricture, and to keep it pressed against it, in contact with the obstacle; and it is said that in general, after a little time, the catheter will slip of itself into the bladder. I have seen this tried, but I cannot say that I ever however, already stated, and proved by witnessed any good result from it. I should think, that if a catheter will slip through in this sort of way, the surgeon would be able without much difficulty to introduce it. Here are two of the last works on this subject, one by a St. George's Hospital, the other by a Westminster Hospital surgeon. I have derived from them a great deal of satisfaction. There is a case related in the work of the latter gentleman which has amused me not a little. The method of securing the catheter is detailed, but I would recommend you to follow the mode you see adopted in this hospital, merely fastening a tape to each of the rings of the catheter, bringing them under the thighs, and then tying them to a handkerchief round the waist. There is no necessity for bandaging up the penis, and putting rings on it, and tring it up in lint and bobbin, as is someinstrument, a gum clastic catheter, was pur down to, and kept in contact with, the stricture. The patient was kept very quiet, and "the catheter kept going a little further in," for eighteen days, without its being passed through the stricture, though all openings in the perincum. As there was no that time the patient was making water by possibility of passing an instrument, how-the side of the instrument. What it was ever small, it became necessary to make an

state,-certainly not the way to tranquitize them ; although Sir EVERARD HOME, al the four hundred and eighty-nine applica tions of his caustics, thought it necessary that the patient should have a bougie put in to keep the parts quiet and tranquil.

Cases of Stricture requiring the Employment of the Knife.

Now, sometimes you will not succeed in passing a catheter into the bladder, and you cannot expect to succeed where the passage is completely closed. Cases of that kind are now and then met with,-cases resulting from injury, or from violent inflammatory action, followed by the formation of matter, loss of substance, sloughing, and so on, in the perineum. In such cases it may be necessary to cut down into the passage, and to carry the knife forwards into the stricture, until you meet with the catheter passed down the sound part of the canal from before. This can only be required where the water flows through fistulous tracts, and none whatever is passed through the natural canal for a considerable time. I have, cases, that you may sometimes succeed in introducing a catheter when no water has passed for some time. I succeeded in one case where the patient had made no water by the urethra for fifteen months; but where the passage is completely obliterated, where it is closed, and closed from violent inflammatory action, (the result, say, of injury,) while the cellular tissue all around is glued up, and there is, perhaps, an extensive deposit and organization of new matter,-in such case you must resort to cutting instruments. I have been obliged to have recourse to these operations in a few cases. One was that of a boy, about fifteen years of age, who had had his urethra cut across. He was engaged in the Carron foundry, and being about some mischief or other, was pursued by one of the workmen, when he jumped out of a window, and alighted on a bar of iron, which stood upright in the ground, in consequence of which he received a wound of the perineum, and had the urethra, it would appear, cut clean across. He was brought to me a long time afterwards, passing his water entirely through incision into the rauk so as to expose the to lodge the inst .ment .. for a time. I h a occasion to pursue this plan, also, in ' e case of a very dreadful stricture, foll ed by abscess of the perineum,-a s' cture resulting from a bruise of the pr neum, in consequence of the .ng from a great height on a man a beam ood many years previously. All s to reach the bladder failed; the atter wa' r was passed with difficulty, and with great straining, altogether, as it has been or many months, through various openings in the perineum. The urine was mixed with muco-purulent stuff. There was resson to suspect disease of the kidneys, in addition to the abnormal state of the bladder and its outlet. Under these circumstances, incision was resorted to for the re-establishment of the passage. In another patient, also, who positively declared he had not made any water through his urethra for about fifteen years, incision was had recourse to. He had been under treatment for stricture, had come to this city, and had had a caustic bougie introduced, rather roughly he thought (by no means an unfrequent source of complaint). This was followed by profuse hemorrhage. On riding down to Woolwich immediately thereafter, his horse shved, and in addition to the injury inflicted by the surgeon inside of the passage, he got a severe bruise outwardly by striking his perineum on the pommel of the saddle. In consequence of these injuries, abscess and sloughing took place, and, in the end, the whole of the water was passed through the openings in the perineum I have mentioned. I am astonished that he should have submitted to this so long, for he was in the prime of life. I should think that he was not much over fifty years of age when he applied to me. When I first saw him, he passed his water through the perineal openings with difficulty, frequently, in small quantities. It was mixed with much ropy mucus, furnished by the thickened congested lining membrane of the bladder, no The bladder must have been very much diminished in capacity, the muscular coat being also thickened. He had great and frequent straining to make water. It was necessary to enlarge this artificial opening, the patient being secured in the position for lithotomy. I passed a catheter down into the perineum, near to the sinus of the urethra; not quite so far, but about four inches down; and on making an incision into the perineum, I cut forwards upon the point of the catheter, and readily carried it on to the bladder; the result was, that the whole of his water came through the natural passage, and he enjoyed himself after a short time, I suppose, just as much as he did before his mishap.

Now in making these incisions, you are not or other cause, the urine is extravasated,

- 4 6114 114 great difficunt in catching the of the canal. It on cut upon an in able stricture, you . w that the canal is greatly enlarged behind; , ou cut in the middle line, from near the apex of the prostate, the finger being placed in the bowel as a guide, directing the point of your knife upwards and forwards, you must hit the passage, and you are not interfered with by vessels. There is no hemorrhage; very little, at any rate. You can make an extensive incision, from the verge of the anus, into the perineum, and there is no difficulty in cutting into the anterior part of the passage. It is only in those cases where no water comes through the passage at all that you are warranted in cutting down, for, in general, by proper study of the parts, and by considering well the nature of the disease, and practising on all occasions the introduction of the silver catheter, you will attain such dexterity in its use, that you will have small difficulty, in almost every instance, whatever the case may be, in getting an instrument into the bladder.

Rupture of the Bladder from Retention.

In retention of urine there are very considerable peculiarities as regards the state of the bladder and the state of the urethra. In strictures the bladder is generally diminished in capacity, as I have before said. It contains but a very small quantity of urine; it can bear distention to a very slight extent, without occasioning unpleasant or uneasy feelings, and without great risk occurring if the viscus be not relieved; but this is not the case in all instances of retention. In some, the bladder is capable of containing two or three pints of water, and it rises up into the cavity of the abdomen exactly as the gravid uterus does, forming a large oval tumour in the "lower part of the stomach, as the ladies and their doctors call it. The belly is swelled, if I may use that phrase. There is a large oval swelling in the lower part of the abdomen. Now in some of those cases there is a much greater chance of the parts giving way, and an infiltration of urine taking place into the cellular tissue, than there is in others. In retention from stricture, more especially where an abscess has been in progress beforehand, there is a greater chance of the cavity of the abscess communicating with the urethra, the parietes of the urethra bursting, and the urine escaping into the cellular tissue, than of the urethr behind the stricture yielding. The ri k in such cases is very great indeed, but the risk of infiltration from retention of urine is greater. In retention from obstruction at the nock of the bladder, from enlargement of the prostate gland, impactment of stone.

ply mentioning the fact. In one case we and the patient observed an absence of the middle and post-lesion of moyar to instrument in, you terior lobes of moyar to the patient of the patie danger is great, yet recoveries often are made, even after the loss of much integument and cellular tissue, the covering of the testicles &c. In cases of

Retention from Injury of the Perineum,

you will in the first instance endeavour to pass an instrument into the bladder, so as to empty it for a time, until the parts have recovered in some measure from the effects of the injury. At a later period, when there is great swelling and some effusion of blood, more especially if the patient have strained to make water, you will have to make a free incision into the perineum, in order to allow the escape of the blood and water, mixed up together. At the same time it is sometimes though rarely necessary to pass an instrument through the lacerated urethra into the bladder. You may in some of these cases be under the necessity of puncturing the bladder. This has been called one of the regular operations of surgery, but it is such an operation as you will very seldom see performed here. Where there is no previous contraction, but where the retention arises from inflammation of the parts, you will be able to relieve the patient, without the employment of instruments at all, by warmbaths, and the exhibition of opium, with the addition of an opiate suppository. If the patient be not thus relieved, you must at all risks introduce a catheter into the bladder, and if there have been no previous contraction, there should be no difficulty in effecting your object. Again, in

Retention from Stricture,

which is the most difficult to manage of ali, there is no faith to be put in opium, the tincture of muriated iron, or anything of that kind. There is then no time to be lost. Have recourse to the catheter at once. parts are altered, and there is very great probability of the arethra suddenly giving way, not bursting, as people say in books, but sloughing, and of entravasation of urine loaded with saline matter, taking place into the cellular tissue. It is not very comoon for patients to recover from this, though frequence the catheter and retain it, because you may find a difficulty, if you withdraw the catheter, in getting it replaced, for the patient may be subject again to retention, so that you will be under the necessity of introducing and re-introducing the catheter; but if you do away with the chance sach. It is time enough to pass the cathe-

pened to come to the hospital at the time, and found that the house surgeon been been foiled in passing the catheter. The passing it is here stated, had been affected by goingrhœa three years previous to this attack and he had never been altogether free from discharge. He more than once had laboured under retention, from which he was easily relieved. However, the stricture had been getting worse and worse, and on this occasion, before his admission, his surgeon had attempted to pass an instrument, without success, and he then sent him here. He had passed no water for twenty-four hours; he had pain and tenderness in the perincum. very likely increased by the attempts which had been made to overcome the stricture. He had been put into the hot-bath, and long and continued attempts had been made to pass the catheter after he had come out of it, but without success. A false passage, it is said in this report, was discovered. He had forty drops of the muriate of morphia given to him, and the following is the report of the house surgeon :- "On Mr. Liston's coming into the hospital, he was asked to introduce the instrument, and by dint of considerable force,"-that I deny,-" and dexterity, he succeeded in passing the ca-I did not use what may be called theter." " force," though I dare say some little dexterity was required, and after the point of the instrument was lodged in the stricture, which you know by its being held firmly, steady pressure was perseveringly employed. The catheter being passed into the bladder, that viscus was emptied. The instrument was quite loose in two days. On the 6th, two days after it had been introduced, it was withdrawn, and he then made water with but little smarting. On the 14th he was discharged quite cured.

Now when abscess forms in the perineum, more especially

When Extravasation of Urine takes place,

you are called upon immediately to make a free opening into the perineum. Make an opening directly into the collection of matter and urine. As soon as this is done, the necessity for passing an instrument into the bladder has ceased, because the bladder empties itself into the perincum, and the water comes freely through the opening. Besides, if the urine be infiltrated into the cellular tissue of the scrotum or penis, you must make many good free punctures, of about half an inch in length ter into the bladder has gone off, after

and the sloughs 1 , we come away.

I have said, 'ast in almost every case it is possible t' succeed in introducing the catheter; h it may happen that you are not able to o so. You may then be under the nece ... y, as a last resource, of

· Puncturing the Bladder.

I ' ve already stated, that you will seld m see this operation performed here. I ave had a pretty extensive practice in these cases both in public and in private, but I have never punctured the bladder yet, and I hope I never shall. You will find the same opinion entertained by other surgeons. Mr. THOMAS BLIZARD, under whom I studied, and no man could be more dexterous in the use of instruments, was decidedly of this opinion. You will find it stated in Dr-SAULT'S works, that he once punctured the bladder, but that was when he had had no great experience in these matters, and when he first took charge of the Hotel Dieu; and he expresses his conviction, that if the case had occurred later in his practice, he should have succeeded with the catheter. But if you cannot manage to give succour by the catheter, why then you must puncture the bladder. You must relieve the patient from his sufferings at all hazards, and it He was in the habit of driving out parties would be better to puncture in all the three places at once-above the pubis, in the perineum, and through the rectum—than to allow the patient to suffer from extravasation and destruction of the cellular tissue.

There is only one other species of retention of urine, and that is, from disease at the muscular apparatus of the bladder-from

Enlargement of the Prostate.

in relieving the patient by the employment gan was in an excited state, and I should of a proper instrument-by a long catheter, such as this,—one at least four or five inches vanced in life—if he had been straining longer than those usually employed, the himself, or over-exerting himself in some curve being large and the heak long. There is no use in poking away with shorter catheters, because you cannot by any possibility reach the bladder with them. The urethra is elongated by the enlargement, by the hypertrophied state of the gland; the prostatic portion of the urcthra is immensely lengthened; and, besides that, the tempt was made to pass a catheter, as I bladder is generally capacious; it is enlarged have already stated, but without success. to an immense extent; after it has become so far distended and bulged for a time into the hollow of the sacrum, the fundus of it difficulty, succeeded in getting a small cabegins to yield, and then the viscus rises theter into his bladder, and drew the water into the cavity of the abdomen, and in that off. The catheter was secured in the bladway the cavity of the bladder is further re- der, under the impression that this was an moved from you than in the natural state; organic and unyielding stricture, but the you require, therefore, a much longer inpatient in his restlessness withdrew it, after strument to reach it. I have seen many it had been in for three or four hours. The

ter; anu patient's roo. instruments o. catgut bougies, castic gum catheter. silver catheters, an 'londy. The instruments have come out filled with blood, but that has been from laceration at the neck of the bladder. On introducing such a catheter as this, however, the water has come away naturally; not perfectly trans-parent, because it is mixed up with mucus of a dark colour. It contains a great quantity of saline matter, and it is in consequence of this change in the quality of the water, when it has been long retained, that such rapid mischief arises on its being discharged into the cellular tissue.

Now there is another cause of retention. and that is, the

Loss of Power in the Bladder

to expel the urine. We had a case showing this very well the other day. The retention was supposed to arise from stricture of the urethra, but my opinion, from the first, was, that it did not arise from that cause. patient stated, that for a long time he had difficulty in making water, and he attributed it to his having been prevented from time to time from emptying his bladder. of ladies into the country, and he could not very decently get off the box to empty his bladder. Upon several of these occasions he had retained his water much longer than he otherwise would have done, and at last, when he came to pass his water, he found that he did so with difficulty. On this ocneck of the viscus, and paralysis of the casion it stopped entirely, and he applied to a surgeon, who introduced a catheter, but did not succeed in getting it into the bladder. When I saw him, the glans pe-In general, in such cases, you can succeed his was swelled considerably, the whole ornot wonder—he was a man pretty well ad-vanced in life—if he had been straining venereal encounter, which it is not very safe in old men to attempt to any great extent. However, in consequence, the parts had become inflamed. He at first passed his water pretty well, although, perhaps, he could not empty his bladder entirely, but at last the water stopped altogether. An at-When the patient was admitted, Mr. WAL-LIS, my house-surgeon, with some little cases where it was supposed that the blad- consequence was that the urine reaccumu-

ply mentioning the fact. In one case we and the patient ONS. observed an absence of the middle and nos-legion of moyar teriophotes of the middle and nos-legion of moyar teriophotes of the middle and nos-legion of the mi terior lobes of mentals of the control of the There was no gonowhites, but the parts were in a state of excitement, and a slight inflammation of the lining membrane of the passage existed, probably from the cause alluded to, and from the use of the instru-

ments. I passed a catheter of a pretty large size into the bladder without any difficulty, and I found that there was no such resistance, or grasping, as is met with in cases of bad stricture. The catheter was retained, and in the course of two days a much larger instrument was passed without difficulty. He says he has had symptoms of stricture for twenty years, especially if he caught cold, and from which he had some difficulty in making water. He has had very little surgical assistance until the retention became severe. He is of very temperate habits. On Sunday last he got wet from the rain, and on Monday he passed his water with difficulty. On Wednesday he applied to a medical man, who attempted to introduce a catheter, but without success, and at about seven or eight o'clock, he was brought to the hospital." Number 3 catheter was then passed in, to about an inch from the orifice, and it was supposed that he had a stricture, though I could not find any. Indeed, I think that if there had been, the passage would not have yielded quite so readily. "He was then put into a warm bath. A little water followed the withdrawal of the catheter. Half a grain of muriate of morphia was then given to him, and fomentations were applied to the region of the bladder. When under the influence of the morphia, a small catheter was passed in, and a great quantity of water was drawn off. The catheter was tied in, but the man became restless, and it came out at 9 a.m. He passed a very good night. Number 4 catheter was put in on the next day, and four pints of water were drawn off."

Now my reason for thinking that there was no stricture, and that the disease was merely a want of power in the coats of the bladder, was that in stricture you very seldom find the bladder so capacious as it was in this case. It is generally contracted, in order to overcome the resistance arising from the stricture. There were four pints of water drawn off here, and in such cases the bladder frequently contains most likely not more than from four to twelve ounces.

I thought it was much more prudent, in is ase, to retain the catheter in the bladder. In cases of over-distended bladder, where the canal is sound, the bladder recovers its tone better when the instrument

o doing so, and it terios lobes of mental percury, 1876. Assort won to do one so, an it time. In woolen, the cash et al. that the bladder could be tent empty, and the world thus have an opportunity of recovering its tone. In a short true a full district was introduced. The bladder was amation of the lining membrane of the state of relieving itself its full and free stream. The patient was any dingly and the made of the lines of the lines are the stream. dismissed cured, after but a very residence in the hospital.

CASE IN WHICH

GOUTY CONCRETIONS WERE EXTENSIVELY DEPOSITED IN

VARIOUS PARTS OF THE BODY.

To the Editor of THE LANCET.

SIR, - I beg to transmit the following particulars of an interesting case, which I obtained on seeing the invalid during a late visit in the country, for insertion in your valuable Journal. I am, Sir, your obedient servant.

T. HERBERT BARKER. North-London Hospital, Feb. 11, 1836.

Mrs. C., ætat. 45, resides at Hemel Hempstead, Herts. She is emaciated, and of sallow complexion. She has never enjoyed very good health. She has had three children, all of which died either at birth, or in early infancy. She has never been accustomed to luxurious living. About fifteen years ago she had an attack of inflammation of the great-toe of the right foot, and of the carpo-phalangeal and phalangeal joints of the middle finger of the right hand, which lasted for some time, and left the parts a little red and swollen. She subsequently had irregular paroxysms, of a similar character, affecting the smaller joints of the hands and feet, and the ankles and heels. About seven years ago, after a severe paroxysm of heat, redness, pain, and swelling, in the joints first affected (those of the right middle finger), she perceived some "chalky matter" deposited in the parts affected, which, previous to its escape, very much aggravated the pain. hy breaking the integuments immediately covering it. Since she first perceived the concretions, their formation has been so extensive, that there is scarcely a square inch of the surface of the fingers, the hands, the toes, or the feet, in which they may not be observed, particularly at the metacarpo and metatarso phalangeal, and the phalangeal joints, which is introduced only as occasion requires, I are so extensively studded with protubcsay twice or thrice in twenty-four hours; rances of various sizes caused by the conbut here the difficulty, experienced by the cretions, as to cause great deformity. She house-surgeon in introducing the catheter, has had not less than a dozen openings in

the feet, and nearly

hands from which great quantities or misse part of 11, 126 has necconcretions have excaped. Their formation five weeks, and discharges a

duri the last six or seven years, the of about the size of a walnut, but is not reds elt ws, the shoulders, the knees, the hips, neither is it, like most of the other protut'& nose, the cheeks, and the gums, have peen the scats of similar pain, heat, red-ness, and swelling, followed by concretions in the right elbow and knee, and on the

left side of the nose.

Her grandmother was a native of Dunstable, and was terribly afflicted with a similar disease. The parents of Mrs. C. were entirely free from the diseases They had never had an attack of gout in their lives. She has been repeatedly told by her friends that the disease was caused by her use of the water of Dunstable, because it was impregnated with saline matter, in consequence of the abundant calcarcous strata in that part of the country.

She has been most egregiously neglected, never having had any medical attendance for her very painful malady. A long time ago, some friends recommended the application of Goulard's lotion, which she used once or twice, with temporary relief from the pain, but she desisted from its further employment, the danger of such applications being represented to her by some other friends as being considerable.

She says that nine or ten years ago she had a severe and long illness, with " brain fever," which was caused by insolation; and that, during the last two years, she has scarcely been free for an entire month from erysipelas of the head and face, or of the parts affected in the hands, where it has generally assumed a severe form.

At the present time, there is a protuberance of about the size of a horse-bean. situated just beneath the skin, opposite the inferior margin of the left nasal bone. It is hard and moveable, and the light-coloured concretion, similar to that which is so plentifully distributed over the hands and feet, is seen through the transparent cuticle. covering it. The fingers are exceedingly deformed, there being clusters of indurated protuberances at almost all of the phalangeal and metacarpo-phalangeal joints; several masses of similar substance are situated upon the dorsa of the hands, and about the wrist. The white saline matter may be observed underneath the disphanous epidermis, of various size and figure, in different

thas always be a preceded by most excru-ciating pain, of the pain has always been relieved by a explication of cold, and much and probably holding some person of aggravate by the application of heat.

Beside the existence of the disease in white colour. The metacarpo-phalau rulent fluid mixed w. ... the saline matter, and probably holding some portion of it in solution, imparting to the fluid a challeywhite colour. The metacarpo-phalangeal which have been enumerated joint of the little-finger of the same hand is berances, painful on pressure even, although it was the seat of excruciating pain at an earlier period of the affection.

The feet are similarly deformed, and the white masses may be seen, as in the hands, covering the toes, heels, sides, and dorsal surfaces.

There are three tubercles of similar concretion; the largest of about the size of a small pea, situated opposite the external condyle of the right humerus. And there is a small concretion deposited on the inner side of the right knee. The pulse is 78, and rather feeble; she has a slight cough, and expectoration in the mornings, in consequence of having caught cold a short time since; the skin is cool and dry, she never perspires excepting during the violent paroxysms of pain, when perspiration and cold shivering frequently come on alternately; and she generally has shiverings and finshes of heat alternate with each other for a short time previous to the attacks of erysipelatous inflammation. The tongue is dry, and covered with a whitish fur; the appetite has always been impaired: she is almost constantly distressed with urgent thirst; the bowels are generally somewhat relaxed; the urine is usually rather small in quantity, and high-coloured, depositing a heavy brown sediment; she has at no time had any difficulty in voiding it. The function of menstruction has usually been pretty regularly performed; at the present there is some little irregularity, which she attributes to the age at which she has arrived.

Remarks .- Similar cases to the above are not very frequently met with. The concretions usually occur only in one or two of the smaller joints, but here there is scarcely a small joint of the extremities that is not involved, together with one of the knees, one of the elbows, and the nose. The age of this poor woman, too, is rather early for their formation.

It presents an instance of this hereditary disease passing over a generation. A tilbugill the patient could not give me much information concerning the case of her grandsituations. The mass, situated at the joint mother, still she assured me that she was between the metacarpal hone and the first greatly afflicted with it. The parents of the phalanx of the left index-finger, is of about patient lived to a good old age, and were the size of a hen's egg,—hot, red, and very completely free from it. This passing: painful, with a small but deep ulceration of hereditary affections over alternate. ply mentioning the fact. In one case we and the patient observed an absence of the middle and pos-

teriorlobes of it in the teriorlobes of it in the teriorlobes of it in the terior time. It is popular in the chalk list which are very somerous in Bedfordire and some adjoining counties), that this lease is induced by the water of those arts, but we need not resort to such an rplaustion, since the chemical composition these concretions, explains the pathogical relation which subsists between gout nd gravel. Moreover, it would be difficult explain their peculiar composition from it imbibition of water from a calcareous oil. The only cases, however, which I have en (three), and one of which I have heard. conred in persons who belonged to such Dr. Wollaston first demoncalities. trated that the real composition of "chalk tones" was uric acid, combined with amionia, potash, or soda, generally with the ormer. It is sometimes combined with me, and phosphate of lime enters into the omposition of some of them. I brought) town with me a few grains of the concreions which have escaped from the hands nd feet of this woman; they are in light passes, of a white colour, soft, friable, and atersected abundantly with cellular tissue, asoluble in cold, but slightly soluble in oiling water. On adding to the solution a aw drops of nitric acid, and evaporating it o dryness, the beautiful purple colour of he purpurate of ammonia made its appearnce, formed by the decomposition of the iric acid, and highly characteristic of its resence. On placing a portion of the conretion upon platinum, and directing a flame y means of the blowpipe upon it, it gave ut a strong animal odour, partly dependng upon the cellular tissue entering into its prination. On continuing the flame it was pparently destroyed; not a particle renained, proving the absence of phosphate of lime; it did not entirely fly off, proving he whole of the alkaline base not to be mmonia. The surface immediately surounding the spot on which the concretion vas placed, was covered with a small quanity of a fosed substance, which was soluble n warm water, and was proved to be disinctly alkaline. It is, then, very probable hat the lithic acid in this case was in comsination with sods or potash. The woman and not been in the habit of preserving the oncrations after their escape, and the quanity that I obtained was so very small, that it was impossible to prove their exact chemical composition. An able chemist has kindly fer to make a quantitative analysis of acse concretions when I shall have obained a sufficient quantity; and probably it a future period I shall be able to publish uore satisfactory information on this point.

To the Editor of THE I WEET.

LOOD:

Sig.—A short time ago, while a perimenting on the human blood, I separate ed from it a peculiar species of petroleumin ad on referring to the analysis given by a eral eminent chemists, I found that this principle was not at all noticed by them. I therefore am led to suppose that it has not befor been separated from the blood, unless very recently, and published in some work which I have not had an opportunity of seeing.

Process.-One pound of blood was taken from a man about fifty years of age, and before separation took place, it was well mixed with one ounce, by weight, of concentrated sulphuric acid, and stood frequently for twenty-four hours. To this mixture was added two ounces of carbonate of lime, and the whole again was well stirred up till effervescence ceased. A glazed earthenware retort was then procured, having its beak lengthened with a tin tube, about three feet long, the extremity of which was introduced into a quart bottle. and the bulb of the retort into a small sand bath, which was placed in a charcoal furnace. A strong fire was gradually raised, while the heak was kept cold by means of wet cloths. Carbonic acid gas first came over, which was allowed to escape; then a most disagreeable smell was evolved, when it was found necessary to lute the receiver to the retort, to prevent its escape. At length a fluid distilled over, and with it the tar. Some floated on the surface, while some formed into globules and went to the bottom. When the distillation was complete, the tar was separated, by filling the bottle quite full of water, and taking the tar from off the surface by means of a slip of glass.

This is the process which I used for extracting tar from blood. For some time I thought it was an oil, and laid it aside as such; but the laws of chemistry do not allow us to judge of substances simply from their appearance, and further experiments proved to me that the product was decidedly tar, and not oil.

I afterwards repeated the experiment, by noting upon eight pounds of sheep's blood; and using the same proportions of acid and carbonate of lime to each pound. From this I certainly expected to obtain a large quantity of tar, but the retort not being glazed, a portion escaped through the pores. Consequently, I was unable to ascertain in what proportion it existed in the blood, but the quantity thus extracted was one fluid drachm.

Animal tar is adhesive to the touch, and lighter than water, and possesses about the same degree of consistency as common:

^{*} See Dr. Copland's invaluable "Dictionary of Practical Medicine," art. " Epilepsy," page 780.

vegetable tar, but it very materially I have, in some cases, seen inflammation of from the latter ip smell, extremely disagreable. It is soluble in alcohol, and tur a of a thick brownish white colour when axed well with water. By evaporating he spirit, the tar again floats on the sure. When ignited it burns like commor r, leaving a smell not unlike that of bur teathers. The quantity obtained bein coo small for redistillation, I was oblized to heat a little in a bulb glass to the tg uperature of chullition, when a spirit was given off which took fire when brought in contact with a lighted taper.

I hope that my experiments will be repeated, provided the result is yet otherwise unknown; not that I think it of great consequence, but we must always feel interested in seeing the secrets of nature unfolded. Transmitting this account for in-sertion in your excellent journal, I remain, Sir, your obedient humble servant,

HENRY OSBORN, Chemist. Southampton, Feb. 16th.

BROWN BREAD.

To the Editor of THE LANCET.

SIR,-Allow me, through the medium of your valuable journal, to call the attention of the profession to the uses and effects of brown bread, both as a remedy in habitual costiveness, and also as an article of diet. I am induced to make these observations, in consequence of having myself experienced both its value as a remedy in the abovementioned state of the bowels, and its iniurious effects when used for any length of time as an article of diet. Its medicinal virtues are really surprising. It scarcely ever fails to remove, in a very short time, that habitual costiveness which so generally accompanies a sedentary life. But when its use is continued for some time after the costive state of the bowels has been removed, its effects are most injurious. It then produces all the symptoms of dyspepsia, and irritation of the whole alimentary canal. The laxative effect arises from the particles of bran which it contains, acting as a mechanical stimulant, and increasing the peristaltic action of the intestines. Now the very manner of its action as a laxative, proves its unfitness as an article of diet : as it is necessary for all substances, in order that they may have any mechanical effect upon the howels, to possess the power of resisting the action of the gastric juice, and all substances that have this power (for instance the rind of vegetables, under which denomination bran comes) also posment of the alimentary canal, and I believe of action.

continued us. of bread coning bran.
Brown bread is any extensively this city, and is an ander the name.
"Constitutional bread," a second that is not deserving. I will at some future period furnish you with cases illustrative of its effects. Believe me, Sir, your obedient servant,

CHARLES WRIGHT.

Harcourt-street, Dublin, Feb. 13, 1835.

SYPHILIS.

"A gentleman who had been cured of a chancre at a distance from home, called to consult me whether he might consider himself as perfectly free from the disease. Whilst he was taking great pains to explain to me how he had been salivated, and how long he had continued the use of mercury after the chancre was healed. I interrupted him by observing, that if he had continued the use of mercury till now, I could not pretend to say whether he was free from the disease. 'How then,' said the gentleman, 'am I to ascertain my real situation?" 'If,' replied I, 'you find no symptoms in the course of three months, the probability is that you will remain well till you expose yourself to a new source of infection." about six weeks he returned, with a sore throat and copper spots. I explained to him that he should not blame his surgeon, who, even if he had known what was to happen, could not have prevented it. The patient went through a necessary course of mercury, till he was cured of every symptom; and then demanded, with some impatience, whether he was secure. 'You are secure,' replied I, 'from every return on the genitals, and on your skin and throat; but, as it is impossible for me to know whether your bones are contaminated, I cannot pretend to say whether you will have nodes in a few weeks' time.' He now began to comprehend the doctrine, and submitted to await the result. In about six weeks he actually had nodes; after the cure of which, by a severe salivation, I made no scruple to assure him, he was perfectly free from the disease."-Mr. Hunter's last conversation with Dr. Adams.

The effects of the venercal poison upon the human body, Mr. Hunter describes under the three different states of "contamis nation," "disposition," and "action." By contamination, he implied the entrance of the poison into, and its contact with, some part of the body. By disposition, the inter-mediate state between contamination and sees the power of producing great derange- the breaking out of the disease, or the state

First, of the state of contamination.

Mr. Hunter was of opinion that mercury, if given immediate the control of the con

—Page 429, recond edition, by Dr. Adams. Dr. Adams, commenting on this opinion, observes,—"This is a fair inference, but its truth can never be ascertained, because the primary diseased action, whether chancre or gonorrinea, has always commenced before

mercury is applied."-Page 433.

The experience of the military surgeons, especially of Mr. Guthrie and Mr. Rose, although of no very recent date, throws considerable light on this important point. Mr. Guthrie, in an interesting paper, in the Medico-Chirurgical Transactions, I believe, vol. viii, observes, — "During the last eighteen months, in the York Hospital, Chelsea, Mr. Dease, Dr. Arthur, Dr. Gordon, and myself, have been in the habit of treating all cases of ulcers on the penis, whatever form or appearance they might have, by simple mild means; that is, by dry lint, or ointment, or lotions, for the most part not containing mercury, in order to obviate the objections that might be made to the application of mercury in any form; and of hear one hundred cases which have been treated in this manner, all the ulcers healed without the use of mercury. The primary sores were of every description, from the superficial older of the prepuce and glans, to the raised ulcer of the prepuce, the excavated nicer of the glans, and the irritable and aloughing alcer of those parts.

"The secondary symptoms, in the cases alluded to, amounting to one-tenth of the whole, and which were treated on the anti-phlogistic plan, have hitherto been nearly confined to the first order of parts—that is, the bones have in two cases only been attacked, and they have equally been cured

without mercury."

"A gentleman, aged 27, contracted venepal sores in the month of June, 1833, and his out under a mercurial course, during which time the sores healed, but he still continued the mercury. While under the influence of that medicine, he indulged in impure connection, the consequence of which was a fresh crop of venereal sores, three or four. The mercurial course was

prolonged until the stelling of these second sores. About two me to as after this, second-side the stelling of the second-side the second-side the second-side the second-side second se

The observation of Mr. Hunter, "that not one in fifty cases of chancre would earner the lucs venerea, if cured locally," when placed in opposition with the experience of the military surgeons above stated, appears to prove one of two things, either that Mr. Hunter was mistaken, or that the poison has become much milder in its

effects

First-Was Mr. Hunter mistaken? Speaking of the acrimony of the poison, he obscrees. " Venereal matter must in all cases be the same; one quantity of matter cannot have a greater degree of poisonous quality than another; and if there be any difference, it is only in being more or less dilated, which produces no difference in its effects. One can however conceive, that it may be so far diluted as not to have the power of irritation. The variation of the symptoms in different persons depends upon the constitution and habit of the patient at the time. What happens in the inoculation of small-pox strengthens this opinion. Let the symptoms of the patient, from whom the matter is taken be good or bad, let it be from one who has had many pustules, or from one who has had but few. let it be from the confluent or the distinct kind, applied in a large quantity or a small one, it produces always the same effect.

In a small pamphlet submitted to your notice, I have stated my conviction, that the poison or poisons producing gonorrhea and chancre do vary in their acrimony, and are arising de novo daily. That the majority of venereal sores are not true syphilis, or, in other words, are not followed by secondary symptoms, and, therefore, require for their cure little or no mercury.

Now, if we can throw off the idea of the venereal poison being like small-pox, a specific, uniform, and unvering poison, and believe that it varies in acrimony, not only from the constitution, but from the habits of life of the patient, then nothing is more reasonable than the belief that the effect will also vary in severity.

It is well known that the disease is milder in France than in this country, which would appear in a great measure to be owing as

No. 651.

the necessity on the p

e very cleanliness and person ver that they may now be pr

pox or paint, three persons, having connection with one female, may have gonornection with one female, may have gonor-rhosa conancre, or bubo; and even these ware lies may vary in acrimony. Now, wille the cause which produces these disfies is one and the same, when once re-Smoved from the woman, it does not necessueffect is not necessarily the same as the cause; for, if so, the excertation from veneral gonorrhoza must be chancre, and the rily maintain its original character; the real gonorrhosa must be chancre, and the excoriation of a chancre must be chancre also, or, if the discharge of the atter comes in contact with the mucous lining of the urethrs, it should produce gonorrhosa, whereas, either of these effects is, as far as I have seen, extremely arre. While, therefore, it is possible Mr. Hunter might overrate the comparative number of cases, which, in the absence of mercury, would be followed by lues venerea, I hold it to be extremely probable that, at the time he wrote (now about fifty years since), the venereal disease or poison possessed a higher degree disease or poison possessed a higher degree cres of acrimony.

At page 274 of Mr. Abernethy's Lectures on Surgery, speaking of the vencreal dis-I had an opportunity of observing in the earlier part of my life."

that venereal bubo is a sign of the absorp-tion of the poison, or, in other words, of the contamination of the system; there is, however, I believe, little reliance to be placed into in the language of Dr. Titley), "is inthe first place, any into in the language of Dr. Titley), irrilation in the urethra or on the penis founded as there handlesis, that the cland may produce a bubo; in the next, secondary stated on sheer hypothesis, that gland-symptoms frequently follow a sore without that chargement depends upon the absorp-bubo; in the third place, bubo, or inflammation of a specific virus."—Page 119. tion of the glands in the groin, or indeed of any part of the body, frequently arises from cold or rheumatism, or any like common causes. While such explanations are at hand, why have recourse to hypothesis, for after all that has been said and done, I contend, that the opinion that the venereal poison is absorbed into the body, is not substantiated by facts or warranted by symptoms.

condary symptoms have arisen from bubo, blished, explain at once the difficulty that

that they may not the females for unaccompanied by any primary sore, I am that they may not of the semales for unaccompanied by any primary sore, I am unaccompanied b nion as hypothetical.

> For lst. I have inoculated a sound person three separate times from three distinct buboes (following venereal sores), without in either case producing contamination.

2ndly. "With respect to absorption, even

Again, as to the venereal bubo containing chancrous matter, it might as well be argued, that when supportation takes place case as described by Hunter, he observes, in any purt of the glandular system dur-"This disease has almost become extinct, ing variola, scarlatina, and rubcola, such or is so much modified as to be unlike that matter would possess the specific property which Mr. Hunter has described, and which of each disease; or, to go on with the argument, that the matter formed from suppuration of a gland, from a dissecting wound, It is an opinion very generally entertained must necessarily contain matter of the same quality as the original. The same reasoning. for aught I see, might be applied to natural poisons, the poison of the viper, &c. treatment of bubo then, in my humble opi-

2ndly. Of the state of disposition.

Mercury cures the action but not the dis-position. "Hence when a part is contaminated, and under the disposition to disease which should show itself at a certain time. mercury will protract that period, and the disease will not show itself so long as the constitution is under the influence of mercury. But all this time the disease will not I shall here take leave, I trust not un- be cured. After the mercurial irritation courteously, to express, freely and unequi has ceased, the venereal disposition, which vocally, my dissent from the views and has existed ever since the parts were contreatment of bubo as inculcated at page 205 taminated, will come into action; that is, of Mr. Judd's recent work on Urethritis and the disease will appear, and in this state will Syphilis. Unless it can be proved that seBrilly Of the state of activ

"Mercapy" cares the ve creal action." we define motive insteady what is veneral action, it at instead action, it at instead definitely of the action is mercury, since daily experience convince time, that many supported by the facts which he produces, effects imputed to the venereal poison, are neither more nor less than productions of the mercury. I conclude then, lst. That the occurrence of venereal sores

while the body is under the influence of mercury, proves that mercury does not pre-

vent contamination.

2ndly. That inercury does not prevent the disease from running a certain course. By this I mean the occurrence of lucs venerca. If this be true, it follows,

3rdly. That the continuance of the mer-cury for three weeks after the primary sores have healed, with a view to eradicate the virus, is perfectly unjustifiable both in theory and practice,

4thly. That there is no legitimate ground for believing that the venereal poison is ever

absorbed into the body.

5thly. That the majority of venereal sores are not followed by lues venerea.

6thly. That the venereal poison varies in acrimony.

7thly. That the majority of venercal sores, which are not followed by lucs venerea, are, in all probability, the production of the some poison that produces true chancre, only in a minor degree of acrimony.

It was my intention to have stated the facts on which I found the opinion, that the more properly speaking, mercurial,-a consequence of the remedy and not of the discase. As, however, these remarks have extended to a length beyond my original intention, I cannot presume to trespass farther! at present on your valuable space.

FRANCIS EAGLE.

29, Poultry, Feb. 9, 1836.

NEW RESEARCHES ON THE

MOVEMENTS OF THE HEART.

FOUNT, and MAGENDIE, each of whom has bodies. formed a different theory. The researches the newest explanation, which is always which is very remarkable, and affects at

existed, whilst attempts were made to crassomething in the vice of an hypothesis. dicate the virus." Page 333. In the mean time BRAU, one of the most intelligent internes of the school of Paris, after having made see val experiments on cold and warm bloode animals, has however contradictory some of the may detail the experiments which form basis of this long memoir, but will refer them in such a manner as will render ou description of M. BEAU's ideas intelligible.

The heart is the seat of two principal movements, which alternate with each other, and on whose existence all writers are agreed; in one, the inferior part of the heart or its apex is carried forwards; in the other it is the superior part or base of the heart which advances, while the point retires towards the dorsal parietes of the chest; we may call the sound which attends the first of these movements the inferior sound (the first or dull bruit of authors); the second gives the superior bruit (the second, or clear sound). It is also very generally admitted that the first is a movement of contraction (systole); the second, a movement of dilatation. Laying aside the manner in which other authors have endeavoured to explain the mechanism of these two movements, and particularly of disease called "venereal rheumatism" is that by which the point of the heart is carried forwards against the parietes of the chest, let us see how M. Beau renders an account of the latter phenomenon. In physiology, all reasoning should be founded on observation and experiment. This grand truth, first established by our countryman Bacon, for the natural sciences, is at the present day applied with success to the investigation of the laws that govern medicine and physiology, by two distinguished physicians, Messrs. Louis and Magendie: the necessity of abandoning hypothesis for observation is daily gaining more Tue theory of the movements and bruits ground, and the time is doubtless not far off of the heart still remains in great obscurity, when the science of life will progress in notwithstanding the labours of Messrs, proportion as we abandon idle speculation BOULLAUD, PIGBAUX, MARC D'ESPINE, for the study of the phenomena of living

The first experiments made by M. BEAU of the Dublin Commission, composed of were performed on frogs. On exposing the Drs. Corrigan, Law, Nolan, &c., ought heart of one of those animals we are struck to give birth, if not to the best, at least to with a double movement of dilatation,

these two movements, we find they depend contraction : parietes or the ventricles on the auricle and ventricle, which act in are shortened in Il directions; the appear the following hnanner, viz. : contraction of drawn up towards the base, and performs a the auricle with dilatation of the ventricle; movement from below upwards, and from contract. Tof the latter followed by dilata- before backwards: on the contrary, the tion of auricle, and the repetition of the impulse of the heart's point takes place sameoprovement. When the heart is ex- immediately before the systole, and depends amflied in the same animal, after the upon the manner in which the blood is Ascular system has been emptied by divi- driven from the auricle against the parietes Gions of the aorts, we can still follow the of the ventricle. This is a point in which movements of the organ for a few minutes: the author is completely in contradiction the auricle first contracts, then the ventricle, with the opinions commonly received; it but not immediately: thus we observe the fol- remains for future experiments to confirm lowing series; -- contraction of the suricle; or overthrow his ideas. Let us repeat them repose; contraction of the ventricle; repose, again to avoid all misunderstanding:more long than the former one: then continuation of the same series. Here there is the ventricle, without any projection foran essential difference between the move-ments of the heart when full and empty: in 2nd. In the diastole the ments of the heart when full and empty: in 2nd. In the diastole there is a general theformer we have a dilatation of the auricles expansion of the ventricle, particularly of and ventricles; in the latter case the dilataties point, which is carried forward and tion is marked by a repose, and hence we strikes against the chest. are led to the conclusion that the dilatations But the above propositions are not the of the heart are passive, and depend on the conly ones in which M. BEAU finds himself force with which the blood is driven into opposed to other writers. If we turn to them. Having thus exposed the nature of the succession of the heart's movements, the heart's movements in a state of plenitude we find a difference which is worthy of atand vacuity, the author asks " How do we tention. explain the projection forwards of the apex M. BEAU, as well as all other writers, adduring contraction of the ventricles? But mit two movements, an inferior and a suhere another question presents itself-Is the perior one; now if we analyze these two systole? M. BEAU thinks decidedly not. sent in the following order :-

apex of the heart really thrown forwards movements, we shall find each composed of against the parietes of the chest during the two other movements, which we may repre-

Inferior movement Dilatation of the ventricle; Contraction of the ventricle.

Superior movement \dots $\begin{cases} \text{Dilatation of auricle;} \\ \text{Rest;} \\ \text{Contraction of auricle.} \end{cases}$

Now if we analyze the succession of movements adopted by authors, we have.

Repore.

Here also the difference between the two systems is striking. M. Brau places the ments of M. Brau were made on animals ventricular diastole between the systoles of with a single heart. To obviate this the the auricle and that of the ventricle; while in M. Hope's explanation we have the ventricular systole placed between the systole rabbits, and birds (experiments for which ceivable.

But it may be objected that the experiauthor continued his researches on dogs, of the suricle and the dilatation of the ven- we must refer to his memoir), and found tricle, a succession which is not very con- that in animals with a double heart, the movements succeed in the following order:-

Inferior movement, compr

Superior movement ...

iorwords; (Augmentation of all the Diminution of the ventricular state. Return of the point to its natura

A beginning, coinciding with the Lilatation of the auricles; middle repose, very sensible;

A termination, coinciding with the col of the auricles.

From the above theory it is easy to deduce the difficulty of diagnosticating disease the author's explanation of the sounds of the nervous system, but surely never was shock of the heart against the thoracic pa- about to detail:rietes; the inferior movement produces the M. BEAU explains the former by the dilatation of the ventricles, and the latter by the dilatation of the auricles.

The first bruit corresponds to an elevation The second bruit is not commonly attended with a similar phenomenon; however, M. BEAU assures us that in six cases he has observed an alternate elevation between the 2nd and 3rd intercostal spaces, corresponding to the second sound of the heart.

The duration of the different sounds, and the repose, as determined by auscultation, by repose of all the parts; one-half by contraction of the ventricles; one quarter by contraction of the auricles (1st and 2nd bruit). The author's researches furnish a different result. According to M. BEAU, if a pulsation measures one second, it composes a true measure à trois temps, and the first bruit, the second bruit, and the repose, will be represented by counting 1, 2, 3.

the heart: it differs little from that given case so grossly mistaken by men of high by M. MAGENDIE: the foundation is the rank in the profession, as the one we are

In the month of April, 1814, the author first sound: the superior movement the se- (M. Bieske) was called on to attend Colonel cond: so far the author agrees with M. Count BLUCHER, son of the celebrated Magenbie; he only differs from him in the Prince of that name. The patient laboured explanation of the manner in which the was troubled with hemorrhoids. The symptwo shocks are produced. M. MAGENDIE at- toms were easily removed by blood-letting tributes one to the contraction of the ven- and purgatives, and the patient returned to tricles, the other to their dilatation: while the amusements of Paris, where he was then stationed; in a short time however he again began to complain of tightness and pain about the head, with impossibility of sleeping. The pulse was now quick and full; the skin warm and dry; the inflammaof the soft parts over the heart's point, tory symptoms were removed by mild diaphoretics and a warm regimen; however, a little confusion in the ideas seemed to remain after the recovery of the patient from this slight attack. Dr. BIESKE considered this symptom, which was soon joined by a return of anxiety, insomnia. and tightness (f the head, as depending upon hypochondria, and hoped, both by acting upon the abdominal cavity and by sulphurcous baths, mineral waters, and relief of the patient's mind, is, according to LAENNEC, as follows; in a to obtain a complete cure. He took this complete pulsation one-fourth is occupied opportunity of examinin; the state of tho wounds which Colonel BLUCHER had received some time before at the battle of Dresden. They were healed, but the cicatrices still betrayed the extent and nature of each injury. One sabre-wound existed near the junction of the occipital and right parietal boucs: it was excessively deep, and had probably penetrated through the inner table of the skull. A second sabre-cut, on the left parietal bone, seemed more superficial; a third, near the junction of the parietal with the frontal bone, on the right side, was also deep, and had probably penewas also a cicatrix on the neck from a lancewound, and a second on the right side of the chest: this latter had penetrated deeply into the substance of the lungs, as was shown by the violent hemoptysis and other lated by M. Bigske, from the last Number symptoms which accompanied and followed the wound. The patient, thus severely of the Berlin Gazette of Medicine which the wound, and taken prisoner, was brought has reached us. (No. 52, Dec. 30, 1835.) into Dresden, where he was attended and

DERANGEMENT OF INTELLECT RESULTING FROM

SABRE CUTS ON THE HEAD.

We extract the following curious case, re-Physicians in an countries are agreed on cured by Baron Labrey, Dr. Oule, &c. Colonel BLUCHER now exchanged better his amortic returned, and, faithful to for a French General, his hearts a control unity the ordenna. of Dr. Bons, he drafik every established, and he followed the allied army day a bottle of commanders! light followed the allied army figures of a winter campaign amidst all the fa from the Rhipe to the walls of Paris.

In the month of May. 1814, the patient left Paris with the intention of taking mine-ral baths, but was prevented by some in-dispositor; he also now conceived the strapes idea that he was possessed of a secree which would preserve the kingdom of Bussia from all dangers, and that his neighcours were constantly at work either to found himself much relieved; however, the force this secret from him, or to deprive him of life, and discover it in his entrails. It was impossible to convince the patient, hy any moral reasoning, of the folly of the ideas by which he was possessed; his physician, therefore, ordered some compound tinct, of bark, with tinct. of rhubarb and wine. The patient now, for a short time, thought himself cured, but his irregular ideas soon returned, and it became necessary to hold a consultation of the most eminent physicians in Berlin; their prescriptions, however, were not followed by any beneficial result, and the patient continued to regard them as fiends and persecuting denions. Dr. Bieske, who still preserved some share of the patient's confidence, hoped to obtain an amelioration, by acting on the intestinal canal, and by exercise; yet it was impossible to overcome the morbid mistrust which constantly occupied his mind; in the intervals of lucidity, he often complained of confusion in the head, vertigo, and sparks crossing the eyes.

Here we cannot help remarking on the stinacy of his medical attendants, in attributing all these symptoms to hypochondria, state of the brain, which had evidently suffered from the wounds received at the battle of Dresden. Far from pursuing an antiphlogistic treatment, the opposite method case) Dr. Bohn, one of the attending physicians, advised him to drink champaigne; under the stimulating influence of which beverage, he felt himself comfortable for a short time; but, on the following night, the patient was very uneasy and agitated, and the attacks of vertigo were excessively violent; the pulse was now full and hard; the face and eyes were much injected; the circulating system was greatly excited. Dr. Bieske ordered some blood to be drawn from the arm, but the patient obstinately refused; he was, therefore, obliged to apply cooling diet. The patient now felt muc's after a lapse of a year without any benefit.

day a bottle of c. mpaigne!!!

The baneful effects of such treatment were not long without manifesting themselves; the vertigo again appeared with excessive violence, and M. Bohn was compelled to order venesection, with a cooling diet, and the use of sulphur. After the abstruction of some blood, and the administration of a few doses of sulphur, the patient sudden change from champaigne to cold water inspired his mind with fresh distrust; he now refused every kind of medicament, determined on treating himself, and for this purpose made a journey on foot into Silicia, from which he returned in eleven days much more ill than he set out.

The patient's state now seemed very serious, and a fresh consultation of the Berlin physicians was called by Prince Blucher. On the 14th of November, 1814, the patient was examined with care, and the physiciangeneral gave it as his opinion, that the disease had no connection with the wounds received at the battle of Dresden, but consisted in an aberration of the intelligence. which would best be treated by occupation, and the effect of moral agents. These latter, however, had no influence on the disease; the patient became so nuraly and distrustful, as to endanger his own life and that of others; he often walked about at night with loaded arms, and once challenged a superior officer in duel, who, he imagined, threw some shade on the glory of his father. A medical examination of the patient again took place, in consequence of this circumstance; a decided opinion of mental deinstead of turning their attention to the rangement was given, and the duel of course prevented; this enraged him to such a degree, that he formed the resolution of insulting, or even killing, his adversary, whenever he might meet him. This design was frustrated by proper precautions, and was pursued with a fatal perseverance; the impossibility of avenging his honour had thus (to resume our author's history of the such an effect on the unfortunate patient's mind, that in the midst of a breakfast given to his friends, he fire: a pistol loaded with ball into the left side of the chest near the clavicle; the wound, although dangerous, was not mortal; the bullet did not penetrate through and through the chest, but seemed to remained lodged under the left scapula; the hemoptysis and other symp-toms evidently showed a wound of the lungs, of which however the patient the completely cured. It is unnecessary to got through the various methods of treatment by turns proposed, but all fruitlessly; confined at one time, at another allowed absolute liberty, the patient was at length sent twelve leeches, and recommend a more neighbourhood of the Rhine, but returned

He now lived without observing any regimen; aspectic goef; dept.

to enjoy excellent health. However, he geemed frequently to anter in the head; the hand was constantly carried to the forehead or head, and the patient at these times expressed his suffering by crying, "Oh, God, my head" (9 flott, mein kop?). His folly now became of an absurd kind; be believed, not only that his food and drink were poisoned, but that a portion of his strength was removed each time the hair was cut, and hence refused to be shaved or have his bair cut; he also conceived that a part of his secret was contained in his excrement, and always satisfied nature in a remote and unfrequented place, after which he carefully buried the precious deposit.

In this melancholy state the patient survived, without any remarkable change, from the year 1814 to the 10th October 1829. The author does not make any allusion to the symptoms which immediately preceded death. The body was examined on the 11th of October.

Antopsy.

External Examination .- A deep cicatrix, two inches long, on the right parietal bone; a second of similar extent near the junction of the parietal and occipital bones on the right side; a third cicatrix one inch and a half over the left parietal bone; on the body a large cicatrix adherent to the second and third ribs on the left side of the breast near the clavicles; behind, near the twelfth dorsal vertebra, two cicatrices; above the right elbow-joint, a transverse large cicatrix adherent to the os humeri; the fingers of the right hand, except the thumb and index-finger, were contracted, and united together by cicatrices; on the outer side of the left calf a round cicatrix, which seemed to have resulted from a gunshot wound, a second over the left knee-joint, from a penetrating wound. On removing the skullcap the dura mater was found to be united to the bone more closely at the points corresponding to the wounds; the anterior one had evidently penetrated into the cavity; the posterior cut on the right parietal bone had also penetrated, but not that on the left side. The whole anterior surface of the hemispheres, superiorly, was covered with a whitish firm layer, about the thickness of a knife-blade, and similar to that produced by ted nothing abnormal. On dividing the difference of the brain the white matter was found somewhat injected, and the ventricles contained a little more fluid than usual. The cerebellum healthy.

In the cavity of the chest the lungs were closely united to the costal parietes; in the small-pox has reconsists the third and fourth ribs, was found a The experience

The third and fourth ribs hard goemed frequently to a wer in the head; the been evidently fractured inwards, and were hand was constantly varried to the forehead on head, and the patient at these times ex
The examination of the other organs repressed his sugging by crying. "Oh, God, vealed nothing worthy of notices."

The cause of the leaion of interligence in this curious case, was evidently chronic inflammation of the membranes capring the cerebral hemispheres. Unfortunitely this cause was completely overlooked by physicians who attended General Bluche and a treatment was adopted which was rather calculated to aggravate than to allay the morbid irritation of the sensorium. This is the more remarkable, as the French surgeons who treated the patient in 1813, after the battle of Dresden, expressed their fears that at some future time the wounds of the head might give rise to a derangement of the intellect. The length of time (sixteen years) during which a large musket-ball remained imbedded in the substance of the lung without giving rise to any symptoms, is also another curious circumstance.

To the Editor of THE LANCET.

SMALL-POX AND VACCINATION
HOSPITAL, ST. PANCRAS.

Report of Dr. GREGORY, Physician, issued Feb. 1836. (Abridged.)

During the past year 401 persons have been treated within these walls, and so many centres of infection removed from the metropolis. Of that number 89 have died, and 312 have been restored.

4140 persons were vaccinated at the hospital in 1835; and 1767 persons, chiefly medical practitioners, were supplied with vaccine lymph, for use, at home and abroad.

The records of the hospital, during the past year, sufficiently attest that the hopes once entertained of banishing the small-pox from the earth are visionary. Thirty-six years have claused since the general diffusion of vaccination throughout this country; yet small-pox still exists, and, by the bills of mortality, may be shown to have proved fatal to 863 persons in London alone during the last year. In various parts of the country it has shown itself during the same period. Nor do other quarters of the globe enjoy an exemption from the disease. On the continents both of Europe and Asia small-pox has recently occasioned considerable devastations.

The experience of the past year shows,

in and about London and the power of vaccination has in no degree diminished. The numbers vaccinated at the hospital in 1835 exceed that of any former year, and in no instance has any doubt or distrust been manifested by the parents of the child-

The r ords of the hospital show further that t) security of vaccination, though so remy, kable in the early periods of life, is not so complete and permanent in after-life as one time might have been anticipated. 144 persons labouring under small-pox have been admitted during the year, who in early life have been vaccinated. All of them, with few exceptions, were adults, an interval, varying from ten to thirty years, having elapsed since the date of their vaccination. Two-thirds of this number had small-pox in a mild form, wholly devoid of danger. The remaining third were less fortunate, having passed through the disease with greater or less degrees of severity. Still the mortality in this class of patients was very small, hardly amounting to 5 in each 100; while the unvaccinated perished in the proportion of 33 in 100. These considerations tend to show that vaccination is still entitled to the highest praise as a means of diminishing both the quantity and the severity of small-pox; that it is an object of national importance to encourage and foster it; and, lastly, that the attention of medical men cannot be too strongly called to the necessity of carefully selecting the lymph they employ, and accurately investigating the several causes on which its diminished efficiency in the more advanced periods of life may depend.

31, Weymouth-street, Feb. 4, 1836.

THE LANCET.

London, Saturday, February 20, 1836.

ANOTHER inquest has been held upon the body of another victim of the satanic system of quackery, and another upright English jury has returned a verdict of "manslaughter" against one of the parties implicated in the abominable proceeding.

But how is it, we ask, that the chief culprit is allowed to escape in these atrocious malpractices? How is it that the principal offender is allowed to pass unscathed from

certainly, that the confidence of the public norant tool of the mercenary destroyer, is on wheel? DE ULITY PAR.

> Many computes have reached us respecting the conduct of the Coroners at these quack victim inquests. Charges of ignorance, allegations of partiality, and imnutations even of corruption, are thrown out against some of those functionaries. That non-medical Coroners must act as blockheads in their offices, is a necessary consequence of their ignorance; but we had hoped that they would so conduct themselves as at least to remain free from accusations of knavery. That many of the non-medical Coroners are most respectable men we freely admit, and hitherto we have seen no just ground for excluding Mr. BAKER from amongst that class. We must freely tell him, however, that his behaviour at the late inquest on the body of Captain MACKENZIE, at the Ratcliffe workhouse, has been viewed by many persons with suspicion, and that reports unfavourable to his official character on that occasion, are in a rapid course of circulation. If Mr. BAKER be capable of forming an opinion on such s subject, we would ask him what he would think of the moral principles of a mar who, in a sound state of mind, would advertise one medicine as a cure for all diseases If Mr. BAKER be not lost to reason, -if his mind be not divested of every portion o common sense, he must know that if there be people so devoid of understanding, se credulous as to place any belief in the in famous puff of the mercenary quack who sets forth such an advertisement, they must necessarily, in numerous instances, pay the penalty of DEATH for their folly.

Under this view of the case, the crimought to be brought home to the offender in the first degree, and whenever it i proved in such coases that the cause of deat is to be found in the poison, or in the effects of Morison's Pills, THE VERDICT OF MAN SLAUGHTER SECULD BE RETURNED AGAINST MORISON HIMSELY. This would be at the inquiry, and that the mere agent, the ig- application of the law to the source of an of the calamities which is at this moment so of Captain Maces were, which concluded, severely affecting society. There any latter several days' sittings, on Wednesday aking so redeeming in the character and last, some hours after midnight, in a verconduct of Monison, that its should be dict of " manalaughter," But we ask, made an exception to the adjusty rules of Is society to continue to endure this evil law at coroners' inquests? Ought he not without making an effort to through it of,to be treated as a Fellow of the College of a calamity almost as fatal in its results, Physicians, or a member of the College of as the plague of the cholera? Whatever is Surgeons, would be treated under similar circumstances? Take the case of either of those legally qualified practitioners, and let us see what would be done. Say that one of the parties in question imagines that he has discovered a remedy for all diseases. He prescribes it in a multitude of cases. It is proved by indubitable testimony, that death, on several occasions, has been the dreadful result of the use of the medicine. Still the practitioner persists. He puffs his own skill, extols the power of his nostrum, and directs the medicine to be again taken. A chemist supplies the drug, in conformity with the direction of his employer. The unsuspecting patient swallows the poison and dies. An inquest is held on the body. Who was guilty of the manslaughter in this case? The chemist or the doctor? The principal or the agent? There can be but one reply to such a question.

But is it manslaughter ! Is it not murder ! We repeat the deliberate and solemn inquiry,-Is not the person who kills under the circumstances we have just stated, guilty of committing the crime of murder? We believe, that some of the best-informed jurists in this kingdom will answer in the affirmative, as we are not aware that any line of distinction can be drawn between the man who, in order to make money, destroys life by poison, and the man who, with a view to enrich himself, plunges a knife into the bosom of his neighbour.

ject further, with reference to any inquests which have been recently held, but we hope was taken at the late inquest on the body was referred to in the Globe newspaper

secret in medicine is based in knavery, and we unhesitatingly state that the time ha come when the system of quackery in medicine must be put down by the arm of the law. At any rate an attempt shall be made to ascertain whether the law be powerf enough to arrest the proceedings and subvert the machinations of a few mercenary and sanguinary adventurers, who now, to the disgrace of the medical profession of England, circulate their baneful and odious trash under the sanction of a Government stamp. Cannot the members of the profession petition both Houses of Parliament for the suppression of quackery? Av. can they! and with every prospect of succes:. In order to accomplish this object, however. there must be co-operation among medical men. Unity of action and energy must be manifested in giving the proceedings proper publicity and influence. If they consider that quack medicines ought to be sold, let them remain passive. If, on the other hand, they consider that the use of quack medicines is injurious to the welfare of society, and is the cause of death to hundreds of their fellow creatures, they are called upon by every sense of duty, justice. and humanity, to take immediate measures for the suppression of this no longer supportable evil.

THE Charter of the Metropolitan Uni-We shall not at present pursue this sub- versity will be laid on the table of the House of Commons on or before the 24th instant. A letter, written by Mr. WARBURTON, on to be able to publish in the next number of the subject of the contents of this instru-THE LANCET, a report of the evidence which ment, to the Lord Provost of Edinburgh,

about a week since. In the absence accurate information on the expect, Mr. WARRURTON has merely adverted to what may probably constitute some of the conditions of the Charter, in general terms. Mibe assured, that no member of the legislature could have been consulted with greater advantage than Mr. WARBUR-Tow. At any rate, that gentleman will have he consolation of knowing, that if the new Charter should fall short of the expectation of the literary portion of the public, he will in no respect be concerned as the author of the disappointment. It is deeply to be regretted, that Ministers should feel that they are too tightly bound down by old customs to make the Parliament acquainted with the principles on which they are about to exercise the royal prerogative in founding a Metropolitan University. It is ever the case in this country, that although we see the coming evil, we have not the mower to avert it, though, to be sure, after it has arrived, we have the privilege of complaining, which must be a great consolation to the neople of a free nation.

The following is the statement which appeared in The Globe :-

" EDINBURGH TOWN COUNCIL, TUES-DAY .- A letter from Mr. Warburton, M.P., in answer to a letter from the Lord Provost, was read, in which he assures the Council that no one could be more anxious to prevent the establishment of any new monopoly of teaching, and to see instituted some uniform system of medical instruction and examination, to serve as a basis for granting to persons properly instructed and examined the enjoyment of equal professional immunities in every part of the United Kingdom. Whether such a plan could be carried into effect by means of any Crown charter, might reasonably be doubted. He thought government would scarcely be justified in delaying to constitute the proposed new University of Lon-don, for the purpose of maturing beforehand, and incorporating with the scheme of that university, a comprehensive measure of medical reform. The Government, he thought, should constitute the new University, investing it with all the privileges appertaining to such institutions, reserving to itself the power of modifying its laws and fordinances, so as to render them generally consonant to any general plan of medical

after be approved of. in points, he was not int that he was aware of bets of specifical schools het no medical achool whatev entioned in the charter by er of importance for which the Landon University was contouding was the Landon University was that no teacher of any medical school, and that no teacher of any hospital shall be a member of the Board of Examiners. The Council directed copies of this letter to be communicated to the Secretary of the University for the information of the Senatus, to the Royal College of Physicians, and the College of Surgeons.

A BODY of young gentlemen having admission to the halls of the University of Lundon, have, after the lapse of a month, come forward in aid of the plea that public examinations should form an imperative feature in the constitution of our governing medical bodies. These gentlemen formed no part of the meeting of medical students who were assembled at the Crown-and-Anchor Tavern on the 18th lustant, for on that occasion the resolution for a petition to the House of Commons in favour of public medical examinations was carried unanimously, and the Chairman was directed to sign the document on behalf of the meeting, without ten hands being raised against the proposition. There is this difference, however, between the proceedings of the thousand and some hundred students who were assembled in the Strand, and the party of students who have since done something else in support of the demand for public examinations. The prayer of the one must be regarded by all as the emanation of a noble courage; the protest of the other is the result of what too many will . ascribe to youthful fear. The demand of the one is addressed to the House of Commons; the decimation of the other to the House of Apothecaries. The car of "marked men" has been raised at the University of London, and the timid and the apprehensive have fallen at the feet of the Examiners at Blackfriars-bridge, with

ESCHEUL LE

College.

this assurance: "We aided not to the con"demantion of your secret "Seconds in
general, or of your put an existing of
"our fellow student Ms. Second in par"ticular."

In speaking of the document, just submitted to the view of the Apotheraries' Company as an aid of the prayer,—and a most valuable aid it is,—of the great meeting of students, we do so from regarding it as an important proof of the iniquitous power and influence possessed by those secret tribunals which can, by exciting the terror of some candidates for examination, extort such a declaration from one third in number of the intelligent students of the most liberal public seminary for instruction in the kinedom.

WHEN a black man encounters a lion, or meets with a bull, he lies down on his back, and pretends to be dead, believing that the giant animal will then only smell and pass on. In the College of Physicians,-to go from a great topic to a little one,-Sir HENRY HALFORD enacts the trembling man. and medical reform the lion, and whenever the lion wags his tail, the cunning President pretends to sleep. But the lion will eat him up notwithstanding. The last occasion on which Sir HENRY " slept " in the chair, was during the late motion "that " Licentiates of five years' standing should " be eligible to be balloted for as Fellows." The mover and seconder having enforced the proposition as a measure of reform which was particularly appropriate at a moment when it was desirable to convince the Government that the disposition of the College was decidedly liberal, arguments in support or reply were awaited, or a tacit assent at once to the motion. However, it had been arranged beforehand by Sir HENRY, that nobody should reply, that the President should prelend to sleep, that every refractory fellow should be borne down with a cry of "question," and that even this trumpery motion for reform should be premptly rejected by the ballot. True to the word of command, mercesolution was acquired by a majority of nearly three to one. The result was

The majority was partly composed of the following members of the Halford faction, samongst others:—Drs. Latham, Wayersteld, Watson, Hue, Fanny, Madmickael, Tunnen, and George Major Bracket, Tunnen, and George Major Bracket, whose name deserves to be written in dail,—while The, Cuarisans, Sarmous, M. Garcon, Horney, and even Dr. Paris, having begun to see the signs of the thung, purposely staid gwey. Drs. Latham and Watson were particularly consulcations in

their outcries against any discussion of so

contemptible a subject as reform in the

Ur to the present hour, we have received no denial from Dr. W. Cummin, of the "Aldersgate School," of the correctness of the allegation, that he is the official colleague of Dr. Macleon in editing a journal which has been systematically devoted, from the first moment of its existence, to slandering the general practitioners in medicine in this empire, and, latterly, especially, to calumniating and vilifying, and fabricating falsehoods directed against, the characters of the students of medicine assembled in the motropolis.

LATE ELECTION

AT THE

RICHMOND HOSPITAL, DUBLIN.

We had not room last week for any part of the letter of our correspondent Observafor in reply to the letters of Messys. CrampTon, Colles, and Carmichael. We now, however, insert an analysis of its contents:—

Observator says that he felt it to be a matter of duty to publish the account which appeared under his signature.—not designing to inflict obloquy on the gentlemen concerned, but to describe facts with fidelity, desiring at the same time to afford the implicated parties an opportanty of publicly rebutting, if possible, the statements which prevailed against them in Dublin. He says that he believed and still believes that his description of the former proceedings as regards hospital elections, of two of the Commissioners, Messrs. Crampton and Colles, were such as should have prevented their nomination on

this occasion, and he alleges that those press like a sentiments on political subjects, two Commissioners in their reprinted to Observation with the whatever Mr. Adams, relieved themselves from the column of the may have expressed, he always voted in allegation that they are "jobbers in public Dublin for anti-referent randicates. Observations of the column of the allegation that they are "jobbers in public medical offices." For instance, he says that at the Meath Hospital, Mr. CRAMPTON and three of his apprentices (one c nephew) fill four of the six medical offices. Observator argues that the appointment of the "Commissioners," though denied, is proved by their admission that they carried on an " official " correspondence with the governtent on the subject of Mr. Adams's fitness for the vacant office. He adds, "I beg also most distinctly to state that Mr. ADAMS was not a candidate until after the Commissioners were appointed," Mr. ADAMS himself declaring to his friends that it would be useless to annoy himself by any application on the subject, as he would have no chance of success with the present Government; and Observator says that he has reason to believe that Mr. ADAMS became a candidate solely in consequence of receiving a communication from one of the Commissioners immediately after their appointment. must, however, be perfectly plain to Observator, that some of the statements in his letter form no reply to the third paragraph of the letter at page 680 of THE LANCET.

Observator stated in his former letter that the commissioners wrote to the government, recommending Mr. Adams's appointment on the grounds that, it was necessary for the support of "the Medical School of Dublin." He says, "I now reassert that they did do. This official letter was in Dublin." Mr. Adams's own possession for some days, and he took great pains to exhibit it, as a trophy, to his friends, more especially to his pupils, as evidence in favour of his capability as a lecturer."

With regard to Mr. Carmichael, Obser-

vator thinks that the following passage in Mr. C.'s letter justifies a considerable portion of the remarks made on the resignation of Mr. CARMICHAEL: I resigned my situation of attending, for that of consulting surgeon; because, by doing so I secured the appointment of two gentlemen, whose long connection with the hospital, and well-tried competency and worth, had been fully established; while, by the arrangements that have been subsequently made, I shall continue my visits to the hospital, &c.

With respect to the remark of Mr. CAR-MICHAEL on the long connection of Messrs. Adams and M'Donnell with the Hospital, Observator says, " I am well aware that those gentlemen have been attached for some time to a school in the neighbourhood of the hospital; but it is a perfectly distinct establishment, and not even situated in the same street with it; nor did they ever hold in it

pater was not the author of the letter in the Freeman's Journal, not was he aware of its existence until he read it as a note to Mr. CARNICHARL'S letter.

Observator concludes by saying,-"You have mentioned in a late number that the authenticity of the petition presented to the Government, purporting to come from the Sisters of Charity, in favour of Mr. FER-RALL, has been denied. I believed the petition was genuine.

We have here reduced into a comparatively brief space, those points in the letter of our correspondent, which we deem it fair, apart from the authority of his name, to publish in reply to authenticated documents, adding that while we know our correspondent to be a gentleman of the highest respectability in one of the professional circles of Dublin, there can be no doubt that he was misinformed on some points discussed in his former communication. With regard to Mr. CARMICHARL, we feel bound to say that we have never before heard even a charge of jobbing in medical elections brought against him, and we are perfectly sure that no surgeon in these kingdoms will hail with greater pleasure the adjustment of medical law and hospital appointments on a just and honourable basis, with greater delight than that gentleman. At the same time we express a belief, founded on pretty good grounds, that no very long period will elapse before the task of exposing errors of medical migovernment under the present system, will no longer need to be one of the duties of the medical reformers of Dublin.

PRESENT TO SIR CHARLES CLARKE.

To the Editor .- Sir, You have been uncessing in your endeavours to elevate the medical profession in public estimation, by fearlessly exposing, on the one hand, its corruption and majoractice to ridicule and contempt, ask as the after, materially por moting its interests by showing a prosper worthy liberality in commending good coduct, and i, therefore, am convinced that you will derive a satisfaction in communicating to your numerous readers the followeven the offices of assistant surgeon." Re- ing event, so honourable to the eminent inpecting the testimony of Mr. CARMICHARL dividual who forms the chief object in it, that he has always heard Mr. Adams ex- which has lately taken place in this county.

Sir Charles Clarke, ever since he became i felt much at a loss to elucidate the mystery, one of our land-holders here here resided as my patient said that Mr. Evans Riadore amongst us during the green prison of war sound unknown to him, and that he each year, and it is not surprising that his wigh professional character should have prompted not only the medical practitioners in his neighbourhood to seek his advice in all cases of difficulty and danger, but that his council should be equally desired by our nobility and gentry. His active disposition made him always ready to attend to the calls of distress, and, to his credit be it told, he has been in the constant habit of lending his valuable services to all those who have sought his advice, without even excepting a fee. In consideration of this liberal conduct, the great bulk of the ladies of Norfolk unanimously agreed to present Sir Charles with a piece of plate, for which a large subscription was immediately made, and an order given to Storr and Mortimer, the goldsmiths, in Bond-street, to execute the same from a design made purposely by Chantrey, the eminent sculptor. I have the honour to be, Sir, your obedient servant.

CHIRCRGUS.

--- House, Norfolk, Feb. 12, 1836.

KING'S COLLEGE, STRAND.

To the Editor .- Sin, -As your numerous readers are extremely anxious at this moment to become acquainted with every circumstance that can elucidate facts relative to the conduct of certain individuals who pretend to be liberal, you may perhaps think it worth mentioning that the Worshipful Company of Apothecaries are pro-prietors in King's College, Strand. This simple fact may of itself be sufficient to account for the King's College students having come forward on the late occasion to land the disinterestedness of the Rhubarb Hall examiners.

I have also heard it rumoured, that in consequence of the want of money at the institution, Sir Henry Halford has been making an indirect application to the proprietors of the Drug Shop' in Blackfriars, to get them to purchase some more King's College shares. I am, Sir, yours, &c.

AUSCULTATOR. Ficcadilly, Peb. 16th.

PROFESSIONAL ADVERTISEMENTS.

To the Editor .- SIR,-While paying s professional visit this morning to an elderly gentleman of fortune, a very small publi-cation, showily bound and gilt, containing three "Introductory Lectures," by Mr. Evans Rindore, was placed in my hands.

could in no way account for the present. I thought at first that there must be a mistake, but in the title page it was plainly enough addressed

"To - Esq., F. A. S. From the Author."

I then suggested that there might be another F. A. S. of the same name as my patient, or that Mr. Evans Riadore, being an F. A. S. himself, he had sent his brockure (a scarcely allowable proceeding, however) to the rest of the fellows; but, on examining the list, neither of these surmises was found to be correct. Upon a cursory examination of these lectures, I observed that they were composed with a considerable regard for effect, and that the author's address was duly given. Now, Sir, I beg to inquire the meaning of all this; and whether Mr. Evans Riadore has presented his introductory lectures to any other gentlemen who are totally unknown to him; and, in fine, whether it is becoming in a member of a liberal profession to follow in the track of the circularcirculating wine-merchants and merchanttailors of the metropolis? - I am, Sir. yours INVESTIGATOR.

London, Feb. 16, 1836.

METROPOLITAN MEDICAL UNION.

To the Editor of THE LANCET.

Sir,-In my address on the state and wants of the medical profession, delivered in the Council Room of the Town Hall, lpswich, in the year 1834. I most earnestly recommended that a provincial association, similar to that already existing in the western division of the kingdom, should be formed. This, with me a very favourite and important object, has been most happily accomplished; but it seems that something yet remains to be effected. The western and eastern associations require a point or bond of union; and where could this be so completely established as in the metropolis? I do most sincerely hope that some leading members of the profession in London will immediately set about the formation of a Metropolitan Association, similar in principle to the Eastern and Western associations. For general and literary purposes we might unite, while we may hold our annual meetings in our own provinces, with the exception of every third or fourth year, when we might meet our metropolitan brethren in London.

Favour me by allowing a space in the pages of THE LANCET for the insertion of this suggestion, and if it should be so fortunate as to meet with your approbation, I trust that you will support it with your

EULOGISTS OF RHUBARB HALL.

674

To the Editor of THE LANCET.

SIR,-In Roderick's journal of last week and is between war,—or they might perhaps, it wosers any processional injury, not to ere this, have been enabled, with the aid of point out the system as one which is degradal little favour at court, to pass the ordeal at high to the profession, and injurious to the Rhubarb Hall,—have got up this document poor. I am, Sir, your obedient servant, expressly to court that very favour. I am sorry that their abilities and diligence need Frampton-upon-Severn, it. In that document they term the 94 who have signed it, a "large majority" of the students of Guy's, but to say the least of it. this is untrue. They also call the proceedings of that meeting "ill judged and riolent," and state that they were "characterized throughout by party violence, which is notoriously false. Now, Sir, from which is notoriously false. which is notoriously taise. Now, our non-the admission of two individuals whose I beg to state that the Coroner for hames are attached to that document. I can assert that neither of them was present at the meeting; consequently they rely on the reports of others in making the allegations of a leagth of time. I am, Sir, yours, to which they have attached their names; obediently, and I believe that very many more, if not the majority of those who signed that paper, were not present at that meeting; and I can positively say that not a few repent having signed it; I have learnt this from their own lips. In addition to this, I may remark, that Messrs. Muggand and Bent induced several javenile pupils (fresh from the country) to sign the paper in question, solely on the ground that they could not do wrong by following in the footsteps of their seniors. These young gentlemen will learn wisdom from experience. I refrain from saying any thing more on the subject of this "protest," than that we are greatly surprised in the Borough that any medical students, of whatever party, should be found

and puttouthe manner in which the worshipped extra mer at Apothecaries' Hall acted when he adestioned god rejected Mr. Smith. I am, Sir, your very beaucafully.

A Gre's Agents A Student.

Guy's Hospital, Pob. 1994, 1836.

NOTE FROM MR. WATER To the Billor. -Sir,-On reading over my litter in your is printed a document headed "Protest of excellent publication, I beg to say that I the Students of Guy's Hospital against the committed a quite unintentional mistake, late proceedings at the Crown-and-Anchor" when I stated that I had attended nine said by Roderick to have attached to it the parishes for eighteen years. Several of them signatures of 94 of the students of that I have so attended, and others in intermehospital: now Sir, I think it right that diate spaces of time. This was what I deyou should be acquainted with the hole-and corner manner in which this "protest" to assure you and my professional brethren has been got up by its promoters, Messieurs that my object in giving publicity to the H. C. Muggand and J. Bent. These buzzing Wheatenburst Poor-Law-Union proceeding. busy bodies, who attend to every person's was not with the slightest intention of doing affairs but their own, - or they might perhaps, Mr. Moseley any professional injury, but to

A STUDENT OF MEDICINE.

MEDICAL WITNESSES BILL.

To the Editor .- Sir, I enclose you a copy of a Petition to the House of Commons, prepared at a meeting of the committee of the "Backs Medical Association," lately is id at Aylesbury. It is now in course of signature, and will shortly be ready for presentation. The support of its prayer will be carnestly requested of the command borough members. I have the honour to be, Sir, your obedient fervant,

ROBERT CERLY, Hon. Sec.

Aylesbury, Feb. 15, 1836.

"." The petitioners draw the attention of quently, a source of useless expense, and

^{* 94} does not form a fourth part of the number of 400, which Guy's Hospital used the House to the fact that a coroner's into boast that it fostered per session. No quest, without efficient medical evidence, wonder that medical reform is a repugnant, can be but an empty form, and is, consetopic in some nooks in that quarter.

The prompiness and spirit with which this petition has been framed, deserve untversal imitation in the profession.

HOUSE OF COMMONS.

Thursday, Feb. 18th, 1836 .- Mr. WAKLEY this day gave notice of a motion for the 17th of March, for leave to bring in a bill for suppressing the sale of secret medicines, commonly called " quack medicines.'

NEW METROPOLITAN UNIVERSITY.

Mr. WAKLEY .- Sir, the petition which I those institutions, and I, for one, never hear.) will consent to the throwing of power into the hands of those who are hostile to the assure the House that the people of Scot-Institutions. (Hear, hear, hear.) But I laboured, should be removed as soon as would ask, in establishing a new university possible. in this metropolis, are we to have another

"in common with the medical profession, they consider it a great hardship ferred must be considered as a monopoly, that the law describe for the following for their important services. They considered as a monopoly, that the law describes of their important services. They are the chancellar of the Exchanged in the specifically, but the present the profession of the control of the Exchanged in the chancellar of the Exchanged is not here, as the promised me that are his intentions tail relief from the restaure, as the Honourable from the restaure in the Chancellar of the Exchanged is the restaure in the restaure should be framed in secret, and that the members of the House are to know nothing of its conditions until the charter has received the sign manual? If that be the case, the abuse of the Royal prerogative cannot too soon be corrected. (Hear, hear.) Indeed I hope the House will now interfere in this matter, and call for a draft of the charter to be laid before it previous to its receiving the sign manual, for such a legal and authoritative instrument should not be promulgated until at least the legislature has been made aware of its express terms. (Hear, hear, hear.) In the constitution of the new university, there can be no law that will compel the students to reside under the immediate observation of the professors, a regulation so essential to their correct hold in my hand is from the Rev. JAMES government and moral conduct; and yet, if ALEXANDER EMERSON, of the Hanwell in charter be one of exclusion, the students Schools, in the county of Middlesex. And at the private schools, where the dormitories he petitioner states, that he has heard with are under the direct control of the masters, surprise and regret that it is intended to will be excluded from the honours of the limit the terms of the proposed Metropoli- university, while those who are under no tan University Charter to two institutions personal restraint or moral management on in London. He therefore prays, that the little part of the professors will receive all House will take into consideration the injustice to other scholastic institutions, of only add that I trust Ministers will cangranting such exclusive privileges to those didly and honourably state to the House two. Sir, I will take the liberty of saying what are the conditions of the Charter, hea word or two on this subject. It is very cause although it is easy enough to say that well known that, in April last, it was resolved by this House that an Address should responsible should it contain any improper be presented to the Crown, praying that clauses, yet I do not know how they are to his Majesty would be pleased to grant a be made so, either to this House or to the Charter to the London University. On public, when the document is completed. I that occasion, a very large majority of the beg to observe, in conclusion, that the genmembers of this House voted in favour of tleman from whom this petition comes, representing that address; and solicitations quests me to state that he forwards it withcame from all parts of the United Kingdom out entertaining any political feeling whatfor the establishment of such an Universever on the subject. He has none. He is sity, in consequence of the manner in which sincerely attached to the Universities of the Dissenters had been excluded from the Oxford and Cambridge, and he desires only privileges of the universities of Oxford and that the public good may be consulted in Cambridge. Sir, I do not complain of the measures that may be adopted. (Hear,

Sir George said, that he could poper authorities of the Universities of land were extremely urgent that the disabi-based and Cambridge or adverse to those lities under which the Dissenters at present

Mr. Tooks said, he apprehended that the scholastic monopoly set up in this king-petitioner had put an erroneous construc-dom? And if a Charter is to be granted, tion on the intended Charter, the petitioner which is only to embrace two or three believing that because two schools only would

be neminated in the Charter, vis., the London University and King's College, that there fore the privileges of the Charter would be confined solely to those schools. The fact was that power would be served to the Examiners of the Mistropolitan University to mane, from time to time, such other schools as should be considered, from their standing and reputation, fit to be added to the number of privileged schools, and which should be entitled to participate in the benefits and honours to be derived from the Charter.

The petition was then ordered to lie upon the table.

THE NEW QUACKERY.—Westminster Medical Society, Feb. 13.—HAHNEMANISM.—We have room this week only for the following:—

Dr. Johnson having moved the adjournment of the debate on this subject last week, he was now requested to take it up. In doing so, he briefly said that homocopathy, he believed, was not the real subject of dehate on the last evening; but the proceed-ings then, rather formed an episode to it, something like a romance engrafted on history. He should leave others to hunt after the bubble, believing that it would burst in grasping. The doctrine of Hahnemanism was founded in error, and too often pursued in knavery, and he was convinced that the home-opathists treated the more urgent cases with our own remedies, and after our own fashion; yet who could expose the fact, for they took the precaution to furnish their patients not only with advice, but with the medicines. When they got old chronic or nervous cases, and not unfrequently imaginary ones, the doctrines of Hahneman were pursued. Chiefly from these reasons, he (Dr. J.) pronounced it to be a system of knavery and deception.

THE governors of the institution entitled the "Free Hospital," situated in Greville Street, Hatton Garden, will commit a gross error if they attempt to purify the air of their establishment by adopting the meathres prescribed in the motion "relating to Mr. Tweeder," to be submitted to their notice on Tuesday next. There is another way of doing that. Mr. Tweepie has in the most straight-forward, prompt, and honourable manner atoned for the exceedingly incautious act which want of experience allowed him.-in common with Mr. J. H. GREEN, Mr. BRANSSY COOPER, and some other exceedingly "orthodox" but older and therefore less excusable gentlemen,-

to commit, and it would be a most united proceeding, after that step, to inflict the supposed punishment on Mr. Tweeder. Let the point be hand distout prejudice; against the charge the cuite sure that the instigations of the surface that the instigations of the honourable-minded arbitrators. The chief parties in the affair should be advised to hesistate about pressing the matter any farther. The candour of Mr. Tweeder, in the admission of his error, and his attempt to redeem it, are, unless we be much deceive! worthy of imitation on the part of the gentlemen who may be his opponents. But why his opponents now?

The Birmingham Journal, of Feb. 13, contains a copy of a memorial presented to the King from the governors, trustees, and medical officers, of the Birmingham School of Medicine, containing a prayer, that " in " order to give additional weight and effici-" ency to the institution," his Majesty would become a patron of the school, and allow it to be styled the "Royal School of Medicine and Surgery of Birmingham." The King consented, through Earle Howe, and at a subsequent meeting of the an morialists. their "humble and grateful acknowledgments" were unanimously voted to be " laid at his Majesty's feet," for his condescension on this occasion.

From a Correspondent. It is generally rumoured at the London University and Hospital, that it is the intention of the Council of the College of Surgeons to grant to the late pupil of Mr. Liston, a public examination. Their amouncement of the fact is awaited with anxiety.

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications, and WARLEY may be addressed to him at all residence, 35, BEDFORD SQUARE.

Mr. —. Nothing could have been more

Mr. — . Nothing could have been more spirited or proper than the application to the Board of Guardians, and the refusal &c., under the circumstances stated.

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

YOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL.

Physician in Chief to the Honital de la Pitie, and Protessor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XIII.

ATROPHY OF THE BRAIN AND SPINAL MARROW.

(Continued.)

GENTLEMEN.-In our last lecture we were occupied with a consideration of drophy of the nervous centres. We described the anatomical lesions which chaacterize that lesion, and the symptoms tecompanying it, but we were not able to complete our subject in a single lecture; et us now then pass to the history of atrophy n other parts of the cerebro-spinal axis, ncluding the pons varolii, the cerebellum, and the spinal marrow.

Atrophy of the Mesocephale

(the pons) has been observed, but this is a very rare lesion; indeed we are acquainted with only one case of this kind; it has been sublished by M. CRUVEILHIER, to whom we we so many interesting facts connected with pathological anatomy. In the case 10w alluded to, M. CRUVELLHIER found the 10ns varolii considerably deformed; it was A least one-third smaller than we find it in the normal state; this diminished volume of the mesocephale coincided with a remark thle atrophy of the anterior pyramidal body m the left side. The subject of this observaility than an atrophy of the annular pro- of Nicussens, we find it has lost in two di-

tuberance. The intellectual faculties were intact; the individual seemed capable of reasoning and judging as perfectly as most men, but a remarkable phenomenon manifested itself in the functions of the organ of language; the patient was quite dumb, incapable of uttering articulate sounds to express his wants, his desires, &c.; yet M. CRUVELHIER remarks that before the first symptoms of hemiplegia had set in, this individual spoke perfectly well. In our former lectures you saw an impossibility of speaking connected with other lesions of the nervous centres; with congestion, hemorrhage, encephalitis, &c. Here the organic change was quite of a different nature, yet the symptom to which it gave rise was the same; another proof of what we have said on the frequency with which various lesions of the brain produce an identical derangement of function.

We have now touched upon the history of atrophy as it manifests itself in the cerebrum and mesocephale; but if we desire to attain an intimate knowledge of this lesion. and avoid all source of error in the manner of estimating its degree, or even sometimes its existence, we must remember that certain parts of the cerebro-spinal axis exhibit a marked difference of volume, according as we examine them at different periods of life. It is certain that the nutrition of the nervous centres is not the same in all individuals and at all ages; hence arises a difference in the

Form, Volume, and Consistence of the Nerrous Centres

with which we should be acquainted, otherwise we may mistake a normal modification for an organic lesion of the brain. You will find this subject treated in a masterly manner, in the thesis of M. CAZAUVIERL, to which we have already more than once alluded. You will there find it proved in the clearest manner that the volume of the brain differs as we examine it in the child, the adult, and the old person. In extreme old age the dimensions of the cercbrum are eviion was affected with hemiplegia; half the dently modified; if we measure the diamenody was paralytic, although no other lesion | ters of the brain, in a person far advanced misted to explain the modification of mo- in life, at the level of the centrum ovale of

rections; the transverse and longitudinal completely absent, the hemispheres of the diameters of this part are diminished by cerebrum are equally absent at the same some lines; the brain is less than that of an time; the disappearance of one sportion adult, both in its thickness and its length. seems necessarily to bring with it the ab.

This difference of volume is not confined to the portion of the brain just mentioned. We the individual is totally incapable of living find a reduction of bulk in various other im- when separated from the mother-stock; portant parts; thus the corpora striats, the malformation, carried to such a degree, adoptic thalami, the mesocephale, all these mits of fetal life and no other. The child differ as we examine them in the young perishes of necessity a few hours after it person, in the adult, and in the old man. The assertions we have just made are not mere ideas, vague and imperfect maxims, unsupported by proof; they are founded bellum has been more or less absent, alupon accurate and repeated measurements which have been made of these different developed in a normal manner; a case of portions of the brain, at different periods of this kind, which is perhaps unique in the

There is, however, one circumstance connected with this subject so remarkable that we cannot pass it over without notice. While the various parts of the cerebrum increase from childhood to adolescence, from youth to full-grown manhood, and In its place nothing was found but a quanthen diminish in advanced old age, the tity of scrous sluid contained in the memcerebellum is the only portion of the brain branes; on each side a pedancle, not larger that does not undergo any change,—that than a pea, was attached to the corpora remains the same in old age, as at any other restiformia, all the rest seemed replaced by a

period of life.

The reduction of the various diameters of tenerum was absent, and the movement the cerebrum in old age has also been estating the content was absented, and the movement the cereblished by another mode of investigation. The properties of the case of cleven years: thus you see that who had passed their seventieth year, the agenesia, or total want of the cerebellum, specific gravity of the brain is reduced by does not necessarily render existence imple to the from the average weight of the adult possible, provided the other parts of the brain. ("Anatomy of the Nervous System pervous centres be well conformed. According to him this phenomenon is constant; however, we would not undertake to render ourselves responsible for its accuracy. In page 271 of his great work on the anatomy of the brain, you will find another example of coincidence of a diminution of one of the lobes of the cerebellum, with a diminution of the testicle in the opposite side of the body; but he does not mention whether this partial atrophy of the cerebellum was attended with any modifiof circulation, and respiration, were carried cation of the intelligence, of sensibility, or of motility. Carried away by the pursuit of a ever, the child is mentioned as being weak favourite idea, he sees nothing but the reand delicate in constitution; a circumstance which is conformable to the opinion of older may present, without occupying himself physiologists, who have attributed to the with the phenomena of still more important cerebellum the power of regulating nutritive systems. Other authors mention cases of atrophy of one or both lobes of the cerebel-In what manner were the generative lum, yet they do not mention any change functions influenced? its Connection with Paralysis.

When treating of cerebral hemorrhage brum (as, for example, into the left lobe of Instead of complete absence of the cere-the cerebellum and right hemisphere of the to absorb the power of the former, and loss of motion occurs only on the side opposite the lesion in the cerebrum; on the other Sometimes this atrophy is general; all hand, when hemorrhage takes place into the substance of the cerebellum alone (the cerebrum remaining intact), we have constantly paralysis in the opposite side of the body. It is remarkable that the same phenomena occur in atrophy of the brain; thus, when the cerebollum is atrophied on the left side, and the cerebrum is, at the same time, diminished in volume on the right ternal examination of the head. The geni- side, the former does not exercise any influseems lost in that of the cerebram, and we tween the parietes of the vertebral cavity. opposite the lesion in this latter portion of the nervous centres. We have examined the archives of our science to determine how far the law now announced, which is fully true with respect to cerebral hemorrhage, may be applicable to atrophy of the cere-bellum. We have been able to discover only three cases of atrophy of one hemisphere of the cerebellum, coexisting with atrophy in the opposite hemisphere of the cerebrum, and in all these three cases only one side of the body was paralyzed-viz that opposite the diminution of the cerebrum. One of these cases is recorded in volume fourteen of the Archives Générales de Médecine; it is also described in the thesis of M. CAZAUVIERL on agenesia; here the patient, a female, was affected with hemiplegia of the left side of the body; there existed in the brain atrophy of the left hemisphere of the cerebellum, and at the same time atrophy of the right hemisphere of the cerebrum. The second case was communicated to the Anatomical Society, hy M. Bonzy, interne in the hospitals, and may be found in the annual report of the Society for the year 1830; this individual had hemiplegia on the right side, but, on the left, motion and sensation were intact; after death were found atrophy of the right lobe of the cerebellum, and, at the same time, atrophy of the cerebral hemisphere on the left side. Finally, our third case has been published by Mr. BELL, of the Saltpetriere, in the " Bulletin" of the Anatomical Society for May 1831; the subject of this observabody. On examining the body, Mr. Bell. found a considerable atrophy of the right cerebral hemisphere, and a diminution of volume, with flattening of the left hemisphere of the cerchellum. In this latter case, the individual was subject to apoplectic fits, and here let us remark the coincidence of epilepsy with a lesion quite different from that to which it is commonly attributed.

Atrophy of the Cerebellum alone, or conjoined.

Sometimes partial atrophy of the cerebellum exists alone, or is accompanied with an opposite state of another portion of the cerebro-spinal axis-viz. hypertrophy of the spinal marrow. M. Hutin has given us an example of this kind in a journal, entitled, " Nouvelle Bibliotheque Medicale," t. 1, p. 34, January, 1824. Here the atrophy occupied the medullary centre of each lobe of the cerebellum; the white substance of the corpus rhomboideum did not exist, but that body was represented by a small pyriform, hard, brown-gray mass; the whole extent of the spinal column was hypertrophied; Imperfect Development of the Spinal Marrow. the chord, instead of leaving a considerable interval, as it does in the normal state, be- spinal marrow may present merely an in-

only find paralysis on the side of the body completely filled it, and was, at the same time, indurated. What were the symptoms in this case? The chief phenomenon was an excessive sensibility of the whole sking The patient was unable to stand upright, because the soles of the feet were too tender to bear his weight. When any part of the skin was touched, he gave signs of excessive sensitiveness, and even great pain, sometimes manifested by convulsive movements. At length the external world became, at every instant, a cause of pain; the unfortunate patient was unable to stir, or place himself in relation with a single object, and he at length died, wasted, exhausted, and literally worn down by painful sensations. This fact is a very remarkable one, and although the history of the case is given by M. HUTIN, with some details, yet we find no mention whatever made of the genital organs.

These are the principal facts we know connected with atrophy of the cerebellum; we may add, that the lesion may exist alone, or in union with atrouby of some other part of the nervous centres: thus, for example, it is not uncommon to find a diminished volume of the cerebellum coincide with atrophy of the spinal marrow. In some cases it is a true agenesia of the chord that we observe, not an arrest of development. Here we do not find any trace of the cerebrospinal axis; the cerebrum, the cerebellum, and the spinal marrow, are all equally wanting; and the fixtus, like those which we have already noticed, is incapable of sustaining an extra-uterine existence. This tion was paralytic at the left side of the lesion is denominated "Amyelia," that is to say, a condition in which

The whole Spinal Merrow is Absent,

while a fluid, contained in a membrane, somewhat similar to the meninges, fills its place, and the nerves, which in a normal state are attached to the chord, seem to derive their origin from the rudimentary membrane. We find, at the same time, two different conditions of the osseous parietes which enclose the chord. In the first, the bones comprising the vertebral cavity are involved in the same lesion as that which has affected their contents, and we find the whole cavity open at its posterior part, or more or less imperfectly formed in the different regions; in the second case, the vertebral canal has attained its perfect degree of development, although the substance of the chord may be reduced to its maximum of atrophy; this is the tame thing that we have already observed for the brain, phere absence of the encephalon coincides with well-formed skull, or with various lesions of the cranial parietes.

Instead of being completely absent, the

perfect development of one or more parts; | gaged chiefly the lumbar renfirment, which the lesion is then called "atelomyclia," and was reduced to the size of a common pen. may exist with a great variety of degrees. Thus in some cases we may find a greater or less portion of the spinal marrow divided, as in the fetus, into two leteral portions, from the absence of the gray substance that unites the two distinct chords; which, at an early period, constitute the spinal marrow. These two primitive chords or lateral portions form, by their approximation, a kind of farrow, which, at a later period, is transformed into a canal; this canal is really permanent in many animals, but in the human subject it is ordinarily obliterated at birth; however, it may persist, and then we find a canal of greater or less extent occupying the centre of the spinal marrow, commencing at the upper part, and seeming to form a junction with the fourth ventricle. In several cases the white or medullary substance appears to be perfectly well develoved, and the lesion of nutrition affects exclusively the gray matter of the chord. Is it to a want of development that we should refer the presence of a canal in each lateral portion of the spinal marrow? GALL described these canals as existing in the normal state, but this is now found to be an chest becoming finally implicated, respiraerror; however this may be, M. In another case, cited by the same author, the brachial and lumbar protuberances were atrophied at the same time.

The Medulla Oblongata

(bulba rachidienne) may also be reduced to such a degree of smallness, as to seem wanting. M. CRUVEILHIER has described a case of this kind in a child, in whom the atrophy of the bulb coincided with an excessive density of this part; in fact, it presented almost a stony hardness; it was also accompanied by a conversion of nearly the whole substance into gray matter. We have already mentioned a case where atrophy of the cerebellum gave rise to loss of speech. In the case just mentioned a similar phenomenon was observed, or rather the child was affected with a great difficulty of speaking; she spoke excessively slowly; pronounced each word syllable by syllable. The power of the muscles that act on the larynx and pharynx was gradually abolished, and the child died from a difficulty of deglutition, joined to a loss of mechanical power of respiration; the muscles of the saw the lateral canals in the bodies of two and death took place in a state of true insane patients (Journal des Progres et des asphyxia. Indeed it may be laid down as Institutions Médicales); in one they existed a general rule, that atrophy of the spinal all along the two sides of the chord; in the marrow in most cases produces a greater or tion becomes gradually more extensive, more intense. The respiratory muscles are at length implicated in the general disorder; a difficulty of breathing sets in ; the patient soon loses the power of dilating his chest, and dies asphyxiated.

Ramollissement of the Brain.

We have now studied two principal leaffection, when we speak of various other diseases of the brain, as, for example, encephalitis, apoplexy, meningitis, &c. They which are attached to it. In cases of partial approach so closely in certain points, that atrophy, one or more of those protuberances we cannot trace a faithful history of the one, may be absent. Thus in a case observed by without frequently introducing the other; apart, if we desire to obtain a correct know- scertain, from either nurse or patient, the ledge of its progress, symptoms, and termination. We must examine it independently of inflammation of the brain, of abnormal injection of the nervous pulp, independently of congestion and sanguineous effusion. In a word, we must study this important lesion by itself, apart from all others, and we shall endeavour to push our investigations as far as the actual state of medicine will permit, although we may occasionally have to repeat our observations, and emptoy, again, certain illustrations which you have already heard in a former part of the course. We will commence with ramollissement of the nervous centres in our next lecture.

CLINICAL LECTURES

SURGICAL CASES,

DELIVERED IN 1836, AT THE

JERVIS-STREET HOSPITAL, DUBLIN,

RY

WILLIAM WALLACE, M.D., M.R.I.A.,

Surgeon to the Hospital, and to the Inturnary for Diseases of the Skin, Venereal Diseases, and Diseases of the Urinary and Genital Organs.

TETANIC SYMPTOMS, OR LOCKED JAW, RESULTING FROM INJURED NERI ES.

GENTLEMEN,-I will commence this day's lecture by relating to you the heads of a very rare and interesting case :-

Philip O'Neill,

A tall muscular countryman, of a sanguineous temperament, and very blue eyes, aged between thirty and forty years, was thrown down, while leading a cart-horse over Essex bridge, when the wheel of the cart traversed his left leg a little below its middle, causing a fracture of both bones, with a communicating wound. He was immediately conveyed to this hospital, and being placed in bed, was treated according to the common practice.

No remarkable symptom occurred until the morning of the seventh day, when I was much surprised to find the bandages and splints greatly deranged. I was the more surprised at this, as up to that period the position of the limb had not sensibly varied from one visit to another, nor did the patient complain, at any time, of any uneasy feelings from position or bandages. Indeed, every thing had progressed in the most favourable manner, from the day of his admission, until that on which the disbegun to granulate, and even to cicatrize. every time he attempted deglarition, a violent Although I made strict inquiry, I could not spasm took place in his threat, by which the

cause of displacement. The bandages were resulting definition and the sandage were resulting definition. The sandage were a proper section and thus the patient was left, and the relief and particular anxiety about 15 turns state.

On the fellowing morning, that is, on the cighth day lefts his admission, I found the

limb again displaced; and I was informed that he had had a very restless night; that there were frequent spasmodic twitchings in the fractured leg; and that he found it impossible to preserve it during the night in the position in which it had been placed.

Such was the commencement of a series of as untoward symptoms as any I have ever witnessed. I shall not detain you with the daily reports of the case, -suffice it to say, that this patient, who had been advancing in the most favourable manner for seven days after admission, died four days after the spasms commenced in his leg; that is, on the eleventh day after the injury was received. The spasms gradually increased, from the morning of the eighth day, and in the course of thirty-six hours arrived at a state which it is difficult either to conceive or describe. Spasm is a bad, or insufficient, term to use. The limb was convulsed, and so constantly and so much, that for scarcely a minute could it be kept either by the efforts of the patient or by the pressure of assistants, firmly in any one position. Indeed, all such attempts seemed greatly to increase the convulsion. It was not only tossed to and fro, but occasionally raised with convulsive force, even some feet, from the surface of the bed. The bandages and splints could no longer be kept on. The wound in the soft parts (which parts had now altogether lost their healthy aspect and had become pale and glassy) as well as the fractured bones, appeared to be quite disregarded, so violent were the pains which the muscular actions produced. The lower fragment of the limb was thrown during the spasms into every possible position; with regard to the upper, it was knocked about like the loose arm of a flail used by a thrasher of corn, at one time being bent forwards, at another backwards, or to one side or the other, at angles of various degrees; and the bones at these periods protruded at the wound to a great extent.

The convulsions of the limb in a short time extended upwards, and then the muscles of the thigh co-operated with those of the leg, in producing the most violent and unrestrainable tossing or dishing about of the whole limb. At the end of the second day after the spasms had commenced, his countenance acquired a tetanic aspect, and he began to complain that his jaws were rigid, and that he could not swallow. Upon placement occurred. The wound had also trying him with a little drink, I found that

violent and constant pain and spasmodic action by exhaustion from absence of all sleep, and from want of nutriment, his countenance became pale and sunken, and his pulse tremulous, rapid, and weak. But the spasms in his limb and all muscular rigidity having at the same time ceased, and the power of degluttion having returned, I could not avoid having some hope, notwithstanding the degree to which he had been worn, that a favourable change was about to take place. On the following morning, however, my expectations were dashed, by finding that the poor fellow was no more; that he had died a few minutes before I entered the hospital, that is about twenty-four hours after the muscular system had become quiet.

I examined the body on the subsequent day, and have preserved this drawing, and the following notes of the

Morbid Appearances.

"The muscular system in general is rigid. and the muscles are marked, as if in a state of contraction. His countenance still presents a tetrate aspect. The pupil of the right eye is confiderably more contracted than that of the left.

further progress of the liquid was tible is protruded one inch through the structed. The situation of the poor tible wound. This leg is some inches shorter than the other, and the state of the muscles and other parts is such, that the limb cannot be by any means devide the state of the muscles and other parts is such, that the limb cannot be brought to its natural length. Having made an incision in the skin, on the outside of the fore-part of the limb, both upwards and downwards, so as to increase the extent of the wound, and having dissected a flap on escil side, the bones are found to overlan nearly two inches. Having next removed the peronei muscles from the middle third of the fibula, the fracture of this bone is observed to correspond to the part where it is crossed by the fibular nerve, as it turns round to the front of the leg; and this nerve lies on the upper end of the lower portion of the fractured fibula, which end is remarkably sharp. The nervo in this situation, and for an inch or two above and below, is preternaturally vascular and much thickened, and the surrounding are soft parts infiltrated with blood, and diseased from suppuration having taken place among them. It is very evident (I have observed in my note of the dissection), from the manner in which the muscles covered and crossed the nerve and the sharp end of the fibula, that every time they contracted they must have pressed the nerve firmly against the bone.

" Head and Spine .- A quantity of a serous bloody fluid exists in the cavity of the arachnoid. The vessels of the membranes of the cerebrum, cerebellum, medulla spinalis, and oblongata, are very turgid. Great effusion between the pia mater and arachnoid-particularly on the superior surface of the hemispheres. An effusion of blood on the outside of the sheath of the spinal marrow, nearly opposite to the middle of the chest. The plexus choroides livid from congestion; some reddish serum in the ventricle; the substance of the brain very firm. and over-vascular.

" Abdomen. - The gall-bladder contains much bile. The capillary vessels of some of the small intestines are in a state of congestion. The intestines are, in general, irregularly dilated and contracted, the transverse arch of the colon, and the cæcum, are much dilated, and the end of the ilium and several parts of the large intestines are irregularly contracted."

Was this a Case of genuine Tetanus or not?

In many points of view it strictly resembled tetanus, but not in others, provided we confine our views of tetanus within the bounds placed by some to the characters of this discase-or, in other words, if we deny the name of tetanus to every disease which does not present certain symptoms, in general considered pathognomonic. The period at which the spasmodic symptoms set in, viz. on the seventh day, and when the wound "Right Leg. The upper portion of the was granulating and even cicatrizing, is the period and the state of the wound at which traumatic tetanus in general commences. The permanent rigidity of the jaws, the difficulty of swallowing, and, above all, the peculiar cast of countenance, were also in a high degree characteristic of tetanus. On the other hand, the manner in which the spasms commenced-that is, in the wounded limb, their gradual extension to the head, the absence of pain in the epigastric region, and of rigidity in the muscles of the abdomen, as well as of any decided spasms of the trunk, are all phenomena unlike what we commonly observe in genuine tetanus. The ceasation of spasms, and the restoration of the power of deglutition, so long before death, are also symptoms which I have not observed in true tetanus. Nor have we any good reason for supposing that in this disease the cause of mischief is scated, as was evidently the case in the present instance, in an irritated or injured nerve, or that there exists such a state of the brain as was on dissection observed in this case. Such are the reflections which occur to me, when I compare the case of O'Neil with the numerous cases of ordinary tetanus which I have witnessed.

The case of Hagerty, noted in the hospital case-book, seems to me to have many points of analogy with the case of O'Neil, and what is important to us on the present occasion, it furnishes those symptoms which have been considered pathognomonic of tetanus, viewing this disease in the common manner, which were wanting in the case of O'Neil; while O'Neil's case affords symptoms, considered equally characteristic of tetanus, which were wanting in the case of Hagerty. I shall read you the heads of

Hayerty's Cuse.

This patient, who was a labourer, aged fifty-four years, was admitted with the soft parts covering the left great toe, much contused and torn, and with a wound of the same shin, or of the front of the leg. These injuries had been caused by the limb having been jammed between a lamp-post and a cart. He had lost a large quantity of blood, and he complained much of pain extending up the leg. On the ninth day, when the wounds were suppurating and granulating healthily, the nitrate of silver was applied, by my directions, to some exuberant granulations on the skin. This application seemed to cause great pain, evinced by loud and repeated cries.

Tenth day. He still complained of pain, and he described it as shooting from the front of the foot and leg along the calf, ham, thigh, and back, up to the neck.

Eleventh day. He had several spasmodic twitches in the limb, which extended up the trunk.

Twelfth day. The spasms in the limb be-

Fourteenth day. The jaws were much more fixed, and the muscles of the neek and abdomen were very rigid. On this day he had frequent general spasms, commencing in the limb.

Fifteenth day. He was as on the 14th, with the addition of pain in scrobiculo

cordis.

Sixteenth day. Stiffness of jaws was increased, but the spasms were milder since yesterday. Slight drooping of the upper evelid; pain in scrobiculo cordis less, Salivation commencing, from the calomel and Dover's powder, which he had been taking since the twelfth day.

Seventeenth day. Rigidity of neck diminished. Rigi-lity of abdomen nearly the same. Had four mild spasmodic paroxysms

since yesterday.

Nineteenth day. Spasms much milder and less frequent; scarcely any rigidity of the muscular system; copious perspirations. Complains of sickness of stomach, or of what he calls a water-brash.

Twentieth day. Occasional, but very mild spasms. Rigidity of jaws, neck, and abdo-

men, diminished.

Twenty-fifth day. No spasms; no muscular rigidity. Suffers much from profuse salivation. Was discharged cured on the 16th of May, about six weeks after admission.

The Symptoms, if combined, in the foregoing Cases, are those of Genuine Telanus.

You may observe, that this case presented, as I have said certain characteristics of tetanus, which were wanting in the case of O'Neil. Thus, there existed in Hagerty's case, abdominal rigidity, pain in scrobiculo cordis, and convulsions of the trunk, during which the body was bent backwards; while certain symptoms were wanting which were found in the case of O'Neil, and which are considered equally pathognomonic as those which did exist. Of these, the most remarkwhich the absence of the tetanic countenant, which was prongly marked in O'Neil, and was partially in Hagerty simply by a drooping of the syelid, and this observable only on the strength day, and perhaps not deserving of the considered expressive of a tetanic countenance.

When the case of Hagerty was passing under my observation, the impression was made on me, that the symptoms originated in an inflammation or morbid state of the peroneal nerve, as in the case of O'Neil; that this inflammation had a limitenced in the nerve so low as in the dorsum of the came more frequent and severe, and he great-toe; that some of its branches, which

passed shrough the wound on the share had two violent paroxysms. One which he had heen irritated by the application to the nitrate of silver; the adaptive of the case-book. His body is so violently bent tritation had sub-relative extended along the scientic persist through the replication of the case-book. His body is so violently bent backwards, that his occiput and heels the scientic persist through the replication to the hed, his trunk and lower space, and up the high to the said-marrow; and that thence resulted the more general muscular affections.

Now it is evident, that if we combine the symptoms of the cases of O'Neil and Hagerty, we shall have all those that occur in the most genuine forms of tetanus. shall, however, have also

One most important Symptom present, which does not exist in ordinary Tetanus,

so far as I have had an opportunity of witnessing the disease for more than fifteen years in this hospital, so famed for accidents. I allude to a spasmodic affection of the muscles of the part injured, and it was with this symptom that the general spasms commenced in the cases of O'Neil and Hagerty; whereas rigidity of the muscles of the jaws. or of the back of the neck, without any pain or convulsion of the limb, however severe or trifling the wound may have been, is the almost uniform mode of commencement of what is called genuine tetanus. In support of this fact, let me recall to you from the case book of the hospital the heads of two or

Three Cases of Genuine Telanus.

Case 1 -Gannon, a strong and healthy child, aged three years, was admitted with a wound four inches long, which penetrated through the integuments, on the outer side of the kner-joint. The joint was not injured. A quantity of dirt and gravel was imbedded in the wound. There did not exist any apparent constitutional disturbance.

Third day. Suppuration commencing. Seventh day. Wound granulating at its upper angle, slongby at its inferior end.

The child looks pale and sickly.

Eighth and ninth days. Restless and pec-

Tenth day. Unable to open his mouth, and when he attempts to take a drink, a slight convulsion ensues, with a tetanic expression of countenance. The power of moving his lips, however, continues perfect, and when he is at rest, his countenance has not any tetanic appearance. No rightity of muscles of either right or abdomen. Evening. His countenance has, even when at rest, the tetania aspect. There exists a Pridity of the souscles of his neck and ab-Monen: and when a convulsion is excited by any attempt to drink, the head is drawn back, and, even when quiet, he is unable to bend it forwards.

Eleventh day. He had several convulsions during the night, when attempting to drink, but was quiet then not excited. His parox-ysms became mine frequent and more sovere during the day. Evening. He has had tion. Pulse 120.

his neck, back, upper and lower limbs, are hard and rigid. All the features of his face are violently contorted. His eyes are turned upwards and inwards. Subsequently, his breathing became laboured and stertorous, and afterwards so faint, that, joined with a state of insensibility, it was supposed he was dead. After a minute or two, however, he recovered, turned on his side, and called to his mother for drink.

These violent paroxysms recurred with an interval of an hour, until about three o'clock in the morning, when he expired.

Case 2 .- Scully, aged eleven years, received a deep punctured wound in the hollow of the sole of his right foot, caused by leaping from a height on a thick blunt hook. He leaped from an ass-cart on the pavement to fasten the trace, which had become loose by the hook falling out on the ground, and it was on this hook he leaped.

Second, third, and fourth days. Accelerated pulse, restlessness, pain in the head, perspirations, foul tongue, sick stomach.

Fifth, sixth, and seventh days. Seemed to be progressing to recovery.

Eighth day. Frequent yawning, of which he himself complained.

Ninth day.-In the morning complained of stiffness in the back of his neck, and difficulty of deglutition. No inflammation in his throat to be observed. No pain in fauces. -Mid-day. Muscles of jaws rigid. Considerable difficulty of opening his mouth; pain felt in the epigastrium, when he attempts to sit up. Muscles of abdomen slightly rigid. The tetanic aspect exhibited in his countenance by a wrinkling of his cycbrows and forehead, and by a divarication of his nostrils .- Evening. Irritability of stomach. Rejects his drink. Very frequent convulsive paroxysms; each lasts, however, only a few seconds; during these, the muscles of the back are contracted suddenly, and, by a quick jerk, throw forward the abdomen. Each paroxysm is attended also by a quick expiration, and an increase of pain, which he refers to the epigastric region, and which elicits a groan. During the intervals of the paroxysms, the rigidity of the muscles of his abdomen and neck continues. He frequently asks to be placed sitting up in bed, and when the attempt to raise him is made, he becomes from head to foot as rigid as a board. When he wishes to take drink, which he can do only while sitting, he is unable to bend his head forward, and asks impatiently his father to bend it. His skin in general is moist, and his face and breast are in a state of perspiraTenth day.—He had a paroxysm every five or six minutes during the night, and, on one of these occasions, the opisthotonos was so violent, as to raise him almost entirely out of the bed. The least exertion he makes, on turning him, or asking him a question, or even any sudden noise, produces a pa-roxysm; and, independently of any excitement, he has one every three or four minntes, but each lasts only a very few seconds. He complains of baving bitten his tongne, and often cries out with pain, which he refers to his loins. He seems occasionally to drop for a minute into a doze-his eyes half closed, but, in an instant, he awakes with a sudden jerk. His stomach is very irritable, and occasionally rejects its contents .- Evening. Paroxysms more frequent-during five minutes he had no less than ten; his pulse during the paroxysm is 138, in the interval 108. Bowels confined; makes no mention whatever of his foot. The wound is nearly healed.

Eleventh day .- Is extremely weak; paroxysms have been very frequent during the night, but they were not so violent, nor did he cry out with them so much, as before. his neck. Has a strong desire to drink, but says there is a stoppage in his throat. Com-plains of itching in his face. His fingers are not engaged during the paroxysms, nor are they rigid in the intervals.

Not to detain you longer with particulars, this child died in a convulsion, on the fifth day from the commencement of the tetanic symptoms, and some time previous to death, great dyspnæa, with delirium, set in.

Case 3 .- Sadleir, aged 30, a strong and healthy labourer, had his right hand jammed between two beams of timber, in such a manner, as to cause the phalanges of the three fore-fingers to be over-extended or flexed backwards, so as to produce a comnound dislocation of their articulation with flexor tendons were torn across, where they cover the joints, and the cartilaginous sur faces of the bones were visible. The metacarpal ends of the phalanges were thrown on the palmar aspect of the metacarpal bones. There was a wound between the thumb and fore-finger, about half an inch long, through which a mass of muscular flesh was protruded in such a manner, that it seemed to be girt by the orifice of the wound. The bleeding was trifling. He complained much of a sense of numbress, but of no pain. The parts were easily restored to their natural position, and the injury appeared then so trifling to him, that when the propriety of removing the fingers was hinted at, he expressed himself so strongly against an operation, that it was not further spoken of.

Third day, Suppuration with much tume-

faction.

Fourth day. Increase of discharge, which is rather thin. The skin of his hand and forearm presents a slight blush of red as far as the elbow.

Fifth day. Matter formed on the dorsum of the hand, in the course of the tendens, and discharged by an incision

Eighth day. Complained of soreness and stiffness of the jaws and throat. His tonsils seemed inflamed and enlarged. In the evening he complained of pain in the epigastrium.

Night day Stiffness and rigidity of his jaws, and leadility to open his month increased. Profuse and general perspirations. Has had two convulsive paroxysms; pulse 102; complains of no pain.

Tenth day. He expired this morning, immediately after a spasmodic paroxysm. It was reported that he had had a spasm, almost every hour, from the evening of the ninth day, until the morning of the tenth: that they became more and more severe; that during the paroxysms his face became almost black; that all night the muscles of the back of the neck and of the abdomen had been in a state of great and constant Complains of pain in his belly, and back of rigidity; that at first the spasms had lasted about one minute, but subsequently not less than a minute and a half.

En passant, I wish to observe, that this was one of the most rapid cases of tetanus which I have ever witnessed, and the violence of the symptoms was by no means proportioned to the rapidity with which the disease ran its course. The patient was kept under the influence of tartar emetic from the first appearance of the disease, until his death, and from what I observed in this case, I would never again think of trying that remedy.

In none of these cases, and if necessary I might detail to you many others, did the wounded limb attract attention, either by pain or spasm. Were there no other circumstance than this, to distinguish them the corresponding metacarpal bones. The from such cases as those of O'Neil and Hagerty, this alone would be quite sufficient; and if the latter cases are to be viewed as examples, they should be considered to form a variety distinct from the former.

There has been much discussion respecting what is

The Wounded Time which is the immediate Cause of Telanus. 2.00 475

You are all aware that the opinion prevails that this disease is produced by wounds we tendinous parts. Are not such cases as those of O'Nell and Hagerly highly suited to cast light on this obscure point in pathology? For example, if the irritation or indammation of a large nerve in capable of influencing the centres of the nervous sys-tem in such a manual and cause a series of symptoms almost dendeal, if not entirely

the state of the s

n some such way that ordinary tetanus is produced. Nor does our incapability of liscovering in this disease organic lesions in he nerves of the injured parts, authorize is to conclude, in our still imperfect knowedge of minute structure, that no organic esion exists. And if the immediate cause of tetanus be seated in the spinal portion of he nervous system, as the inquiries of my riend Dr. Ruin of this city, and, subsequently, of others, go to prove, an additional erring that it is an injury of the pervous issue that gives erigin to tecanic disease, and not of either the tendinous, or, as some suppose, for example the late Dr. PARRY, of the muscular.

It is remarkable that the effects which we know to arise from an irritated nerve, are always more severe a few days after the injury has been inflicted, than immediately on its receipt. This corresponds with the phcnonicia presented by tetaniis. For the symptoms of this disease rarely indeed commence for some days after the infliction of the injury which causes it. In the cases of O'Neil and Hayerty, the nervous symptoms began, as I have already observed, about the same time, and in the same state of the wound, as we would have expected tetanus. Thus in O'Neil, the first symptom of nervous mischief was on the eighth day, and in Hagerty, on the tenth day, while in the cases of Scully and Sadleir, they commenced on the eighth day; and in the case of Gannon on the tenth day. This points out a close relationship among these affections.

In the memoirs of Baron LARREY, you will find many facts, which, in my mind, demonstrate the probability that a local injury of nerves is the immediate source of mischief in tetunus. He often noticed, for example, a remarkable connection between the character of the tetanic symptoms and the situation of the wound which caused them. He observed, both in Egypt and Germany, that when the wound involved nerves in the front of the body, the symptoms were emprosthotonic, and when those on the posterior part, opisthotonic; but that when both classes of nerves were injured, complete tetanus ensued. It was also a course of the larger nerves were very often followed in the climate of Egypt by tetanus. But; what is still more to the purpose, you will find on record some cases which are re-

gical Journal, where of tetanus in which he subject.

imilar, with those of genuine tetanus, we [performed amputation with temporary reare prompted by analogy to infer that it is lief, and when he examined the amputated limb, he found that the branch of the median nerve going to the thumb was torn two-thirds across, and its extremity inflamed and thickened for nearly an inch. He also, subsequent to the death of the patient, found about two inches of the same nerve at the bend of the arm, very vascular, but without effusion or thickening of the envelope.

Dr. HENNAN has, in his Military Surgery, mentioned that he found the radial nerve thickened, and a small splinter of bone sticking in it, in a man who died of tetanus.

Baron LARREY has recorded the case of the son of a general officer who died of tetanus, consequent on amputation; and upon examining the stump, the median nerve was found included in the ligature with the artery. He also mentions a case in which he suspected that tetanus was caused by a ligature on the crural nerve. He removed the ligature, cauterized the nerve, and the man recovered.

You will also find, in the first volume of LALLEMAND'S Researches on the Brain and its Appendages, the case of a soldier, aged about 38 years, whose subclavian artery was tied for aneurysm. When the ligature was drawn tight on the vessel, the patient experienced great pain in the neck. This pain diminished the next day, but on the fourth and fifth days it became very severe. On the seventh night, there was "perte de connaisance," particularly of the inferior limbs. (LALLEMAND conceived that the convulsions of the upper limbs had been prevented by the bandaging) Immoveable pupils, short and frequent respiration, small and irregular pulse. On the eighth day the head was drawn back hy spasms, and death took place in the evening. On dissection, it was found that the ligature on the subclavian artery had included the branch of the brachial plexus, which comes from the third pair. An abscess was found in the posterior lobe of the left hemisphere. The vessels of the cerebral substance, and those of the pia mater, were preternaturally developed, and the ventricles contained some reddish serosity.

There are probably other cases of an analogous kind on record, which I have remark made by him, that wounds in the either not read, or which may have escaped my memory. Those which I have mentioned are, however, quite sufficient, in connection with the two which we have ourselves witnessed, to authorize us to conclude The as cases of telanus, in which there that there does exist a form of tetanic dis-was an injury of same more or less similar ease, which is in very close relation with, to that which occurred in the case of it not entirely dependent on, an injury of a O'Neil, and probably also in that of Hagerty. nerve. May we not, as I have already said, Mr. Liston, one of the able professors of consider such cases as forming a peculiar surgery in the University of London, has variety of tetanus? This seems to me to given us, in the Military Medical and Sur- be the more correct way of considering this

When we reflect on the different results situated, and in the third, they were accomwhich have followed the same kind of treat- canied by a triding and rather agreeable ment in different cases of tetanus, I think we are compelled to believe that authors have included under this term many forms of disease which differ so essentially from each other, as to require dissimilar modes of treatment. This would certainly be a natural way of accounting for the discrepancy which exists among reported cases.

Of the various Modes of Treatment .

adopted, there are few that have afforded more discordant results than that by smputation. It is, in general, now never thought of; yet LARREY seems to have obtained advantage from the practice, and even from the division of the nerve leading from the injured part. I confess, that when I reflect on the facts connected with this subject, I am disposed to conjecture that the cases of tetanus in which this mode of treatment will be beneficial, are such as those we have been considering; and I have scarcely a doubt on my mind, that, if amputation had been performed at a sufficiently early period, or the irritating extremity of the fibula removed, or even if the injured nerve had been divided in some part of its course, between the spine and the seat of injury, the life of O'Neil might have been saved.

Should further investigations lead to the conclusion that there is a peculiar form of tetanic disease, which has for its cause an injury of a large nerve, and that these are the cases in which an early amputation, or the division of the nerve between the injured part and the brain, is likely to be useful, our attention will be directed to distinguish such cases from others; and I am induced to believe, from what I have seen, and for the reasons already advanced, that the situation or part in which the spasms commence will be a powerful assistance, as a

Means of Diagnosis,

if not of itself sufficient. It is to be regretted that in the recorded cases I have mentioned, and in which the symptoms were connected with an injured nerve, no notice has been taken as to the exact manner or situation in which the spasms commenced. They do not, therefore, afford us the assistance on this subject which we might otherwise obtain from them. RICHERAND says, that he has sometimes noticed in wounds which threaten tetanus, that a persevering extension of the lumb during sleep often manifested itself before other symptoms were observed. Do such cases belong to the class of tetanic affections which arise from injured nerves of large size? To the same class most probably belong also three cases of tetanus recorded by Sir GILBERT BLANE. in two of which the symptoms affected the side of the body in which the wound was

sensation in the part.

If there are the second of tetanus depend-at on the second of such an experience of the second rm calls as putation of the division of form calls? the injured nerve or the removal of the irritating cause, it must be clear, from the facts unfolded by the case of O'Neil and by the cases recorded by LALLEMAND, that such cases will not be benefited by such operations, unlimitately be executed early, or hefore the disease has extende I so far as to cause inflammation of the central portions of the nervous system. This precisely corresponds with the rule of practice given by LARREY: he advises that they be performed before inflammation commences.

Mercurial treatment has often been supnosed to be useful in tetanus; and in the case of Hagerly there could be little doubt, from the close connection observed between the improvement of his symptoms and the commencement of salivation, that material service was obtained from the action of the mercury. Will further experience sanction the conclusion, that it has been in cases of tetanic disease arising from the injury of a nerve, that mercurial treatment has been serviceable?

In conclusion, and as my only analogy for having occupied so much of your time with this lecture. I have to observe, that should it turn out, that it is in cases of tetanus from injury of a large nerve, that advantage is to be expected from mercury, or from amputation, or from the division of a nerve, cr the removal of causes of irritation; and that the diagnostic symptoms, which I have laid down, are sufficient to distinguish these varietics of tetanus from others; it will thus be admitted, that a step has been achieved in the study of the symptoms and in the treatment of a disease, respecting which every thing seems to be, as yet, in confusion. The facts which I have witnessed those which are on record, and the reflections which both have created in my mind encourage me greatly to endeavour on ever opportunity to ascertific the distinguished peculiarities of each care which may present itself to me. In sheet, I feel convinced that one cause of fallure in the treatment of this disease, has arisen from our great neglect of its varieties. 12. 118

ST. GEORGE'S HOSPITAL

CLINICAL LEG

Delivered in the Session 1835-6. BY MR. WALKER.

GENTLEMEN,-It is my intention to bring under your notice this marring the par-ticulars of a very interesting case which presented itself a short time since amongst the out-patients under my carc. It was one of ruhlingual tumour, occupying the usual situation, but differing in some points from that form of disease which is known and described to you under the name of " Ranula."

The patient, Elizabeth Holloway, an inabout two years ago, that a small tumour was growing under her tongue. At this time it was no cause of pain or inconvenience, either in swallowing or speaking, nor would she even have been aware of its existence had not her attention been drawn; to it by a female relative who had herself a few years previously suffered from a tumour in the speech of the patient. A few mouths since, the tumour, from having remained quiescent, began gradually to increase in size, and materially to interfere with the functions of the parts in the vicinity of which it was situated. Swallowing caused her inconvenience rather than pain, and her voice, from its natural soft tone, changed into a note much resembling that of a frog's croak. It is, in fact, from this peculiarity that the disease has obtained its name of ranula. Her voice was thick and reedy from the pressure caused by the timour (which had now attained the size of a pullet's egg), upon the superior portion of the laryux. The living mucous membrane of the mouth moved easily over the surface of the tumour, and there appeared to be no impediment whatever to the natural flow of saliva. You may remember that at about this time I introduced a blunt probe into the ductus Whartoniensis. "It did not this title the tumour, but passed downwards to his lander surface, a circumthe tumour will structed in the cellular structure under the tongue, and altogether unconnected with and unattached to the sublingual ducts.

tumour removed, and I accordingly operated verified .- Rep. L.

in the following manner: - She was placed in a window fronting the light; the head was thrown backwards and supported; the motions of the tongue were checked, and commanded, by its apex being pressed against the bony palate of the roof of the mouth. Whilst in this position, the mucous lining of the mouth, which was kept on the stretch over the tumour, was divided in that situation by the laucet, and the cyst of the tumour was exposed. That was next divided, and a considerable quantity of thick atheromatous matter immediately escaped. On examination I found the cyst to be much firmer and denser in structure than is usually attained in these cases, and of sufficient tenacity to bear some firm manipulation. I secured it by a pair of common dissecting forceps at the opening previously made through the mucous membrane, and dissected it out with a flat aneurysmal probe. At its inferior position it was attached to the mucous membrane by a small peduncle, of about the size of a crowquill, which was divided by the scissors. teresting healthy-looking girl, about 19 The operation proved troublesome, from the years of age, perceived for the first time, escape of the contents of the cyst. and the escape of the contents of the cyst, and the inconvenient and awkward situation which it occupied, as the cellular structure at this part is loose, and but little force is required to detach or separate it from a tumour of this kind, and I should therefore always advise you to effect this by an instrument similar to the one which you saw me useviz., a flatened ancurysmal probe. The use occupying the same situation, and who was, of a knife in operating on these parts is therefore, more sensible of a slight lisping dangerous, from the chance you run of wounding any of the sublingual vessels, which are of a large size, and the little control which you can have over the movements of your patient, for I can safely promise you that you will find few so quiet and tractable as this patient was. After the tumour was removed, the situation it occupied was carefully examined, and finding that the whole of the cyst had been removed, and that there was no hemorrhage from the part, I ordered her to rinse her mouth out frequently with warm water, and to take a pill of calonicl and autimony at night, and a senna draught on the following morning, and at her very urgent request I allowed her to return home to her friends in the neighbourhood of Coldbath-fields.

Thus much of this case, gentlemen, you were most of you enabled to witness, and I regret the more that I could not prevail upon the patient to remain for a few days in the house, as it is during that period that the most important part of the treatment in such a case as this is called for.

^{*} On examining the tumour previous to its being placed in the Museum in Grosvenor-She was extremely anxious to have the place, we found the above remarks fully

Twelve hours after the operation she was completely relieved; and, as I before told you attacked with great difficulty of breathing; if your patient he young, vigorous, and pleand deglutition, which continued unabated until I saw her on the following day, about the take a large quantity of blood in a texenty-flour hours after the operation. It is to from the arm, and afterwards found her tongue enormously swollen, readering it impossible for me to examine the throat. Extra attempts which she made to with the approaching the property of a terminal expansion which she made to with the approaching the property of the and turgid; skin hot and school; pulse 120, rapid and thready; and an expensive nance expressive of the grant anxiety. Now, with symptoms such arxives it may frequently be requisite, in full, strong, and plethoric persons, to abstract blood largely from the system, and produce a decided impression at once, but in more delicate subjects topical bleeding will be found quite sufficient to answer this purpose; but even this you must do effectually, and check the inflammatory action at once. Twentyfour leeches were ordered to be applied to the throat, followed by a linsced meal cataplasm; six grains of calomel and five grains of James's powder were administered immediately, and were followed in four hours by a strong senna draught. The leeches were re-applied on the following morning, for although the painful sensation of suffocation about the throat was materially relieved, there still remained sufficient difficulty in deglutition and respiration to render their re-application a matter of prudence-She took the infusion of roses with sulphate of magnesia and diluted sulphuric acid every six hours, for a few days, when she continued to go on without any further let or hindrance to her perfect recovery.

The Symptoms which sometimes follow an Operation on Parts near the Throat,

where there is required any force or violence to separate the morbid from the healthy structures, are frequently of a distressing, and sometimes of an alarming character, and the consequent restorative inflammation, if I may use the term, which is naturally set up in the part for the reparation of the injury, frequently affects the surrounding important organs of respiration and deglutition, in the manner which I have already described to you occurred in this case; the same symptoms occurred in the patient M Donald, after I had removed the tumour, situated externally, near the region of the parotid gland, and dipping downwards and forwards under the angle of the jaw; but they were speedily and effectually relieved by the same means being employed as above detailed. In the treatment of these cases you must be active at the onset, and attack them vigorously; you must not be satisfied with putting on six or eight lecches, but you must apply a couple of dozen, and peat the application of them very soon, if course, Nature, and Transman you do not find the symptoms speedily and that disease I mean which the symptoms speedily and

action.

The Disease in the present Case

(Holloway's) did not partake of the ordinary character which is usually obtained by the sublingual tumour denominated ranula, but came more properly and particularly under that class of tumours which is denominated encysted. It was unconnected with the sublingual duct, and was situated in the toose versity states beneath the tongue. It is not very said man so meet with en-cysted samours earlying this situation, the cyst. however, at mountly found to be very thin and attenuated, and the contents are most commonly of an albuminous glairy character, resembling the white of an egg. Encysted tumours of this nature are frequently met with in other parts of the body; I have removed them from the labium pudendi, and from the inner surface of the lips; they seem to occur and form under surfaces covered by mucous membrane, and where glandular apparatus abounds, more frequently than in other parts. They seldom admit of removal by dissection, from the extreme delicacy of their texture, this circumstance rendering it very difficult, and almost impossible, to separate them from the surrounding parts without leaving some portion of the cyst behind; and when this happens, you may be pretty sure and certain that the disease will return again. The method of proceeding where extirpation is impracticable is the following; you must proceed in the first steps of the operation as I have already explained to you ;-freely divide the mucous membrane of the mouth and the cyst itself, empty the envity of all its contents, and allow all bleeding to cease. Then wipe out the cavity with a piece of lint, and rub over the whole of its inner cavity with a piece of caustic potash, so as completely and entirely to destroy the whole cyst. After this is done, you may if you please wash out the patient's mouth with some vinegar, which, by decomposing the caustic, will check its further action on the surrounding parts. The stigs of the cyst will separate in a few says, granulation will spring up from the option of the carly, cicarrization will take the care, and the cure will be thus effected. will be thus effected.

I will now details you a few minutes by explaining to you the

denominated "ranula." This, like the end shouphate of lime, are often met with; they cysted tumour, generally occupies some saidon produce any inconvenience, nor do part of the cyclic terminates and the said of the lower of the lower of the lower of the said a consequent accumulation in the duct, the secretion becomes inspissated, and mixed with the mucus poured out by the lining membrane of the canal, and in this way a tumour, sometimes of considerable magnitude, is produced. When it is practicable, some authors have recommended the introduction of a small probe that the mouth of the duct, and treat the constricted orifice by gradual dilatation, as in the cases of strictures of other macous canals. this way I have known the distended cavity to have become emptied, and a free exit established for the subsequent secretion of mucus to escape. When the orifice of the duct cannot, however, be re-established in this manner, the treatment of it by caustic potash is the best; or, if the tumour he a very large one, the excision of a portion of the mucous membrane, with the parietes of the cyst, may be substituted for simple incisiou. This is the method which I should advise you to adopt, but other plans besides these have been recommended. The nitrate of silver has been proposed, and will, I have no doubt, often succeed; its object is precisely the same as that of the caustic potash, that of destroying the cyst, but in this respect I rather believe that it is less to be depended upon than the kali purum. There is another mode of treatment which is sometimes adopted in these cases; it is one, however, which I feel it to be my duty strongly to caution you against -it is the introduction of a seton. A skein of silk, or part of one, is drawn through the substance of the tumour, and tied in a knot closely under the tongue. The object of this method of treatment is manifest; it is that of producing inflammation and consequent obliteration of the cyst. This is a very nasty mode of proceeding, independent of its being a very dangerous and inefficient one; I have seen it productive of great inflammation in all the surrounding parts, and attended with the severe treatment, would prevent my ever having recourse to it.

Besides the accumulation of saliva.

Earthy Deposits in the Salivary Ducts under the temperature pally formed of the

swence in the mouth. I have removed several, and one a short time since from a girl who presented herself among the out-patients. This was of a larger size than any which has previously fallen under my motion it was about the size of a horse-bean. There is of course no reason why they should not attain a much greater size than this. They may be removed by a very simple process. You have nothing to do but to divide the membrane of the duct with but to divide the membrane of the duct with the point of a lancet, and you can then easily dislodge the calculus by means of the edged extremity of a probe; it will generally escape without any assistance, after the division of the parts. It, however, sometimes happens that the presence of a calculus in the ductus Whartoniensis is productive of considerable inconvenience to the patient, and escapes from the duct without operation. This occurred in a case (the preparation of which I now show you) which was given me by a friend some short time since with the following history. The patient had suffered for several years from pain and uneasiness at the inferior surface of the tongue, and from a painful spasmodic affection of the miglo-hyoideus muscle, the stone was discharged during the night from the duct, and all her former painful sensations immediately left her.

ON THE

LAWS OF SICKNESS. ACCORDING TO AGE.

EXHIBITING A DOUBLE COINCIDENCE BE-TWEEN THE LAWS OF SICKNESS AND THE LAWS OF MORTALITY.

By T. R. Edmonds, Esq., late of Trinity College, Cambridge.

THE law of mortality of any population, consists in the expression, for successive ages of life, of the number dying out of a symptoms which I enumerated to you in a given number living. Similarly, the law of former part of this lecture as occurring in the face of the law of sickness will express the number constantly the face of feverish excitement at that age. The law of sickness, as will express the number living the face of the whole system at that age. The law of sickness, as will express the number living the face of the whole system at that age. The law of sickness, as will express the number constantly increased the second at the second control of the second c ately inform us how many individuals at a given age are yearly attacked by sickness. This law has regard to the duration, and not to the number of cases of sickness suffered by a given number of individuals.

There have been published only two

observations on the law of sickness, was According to this new theory, the mortality from returns collected by the Highlast Later by year of age, exceeds that of the Society of Scotland, the other from returns by the large year by 5(2.991) per conta which recently collected and just published by the large as saying that the mortality "Society for the Diffusion of Useful Know-ledge." In the former, 85,000 years of life, the training of the have been one-the observed. The period of life observed, extended from the age of 20 to the age of 80 years; but for ages above 60, the results absolute sickness at each age, as experienced are not deserving of much confidence. In in the Scottish and English benefit societies, are not deserving of muce considered. In in the scottiss and larging nemoticenes, both observations, the quantity of sickness together with the relative results according suffered by a given number living increases to theory. The absolute numbers for Engwith the age according to the samp gate. In the British Medical Abmanck for 1836, from of increase in the mortality according to age; the pen of the editor of that valuable work. and is expressible by the number or "con-stant" which I have used in the construc-tion of all my theoretical tables of mortality, between the ages of 15 and 55 years.

in in interval of acc, exceed a ding delimination of the state of the

	Relative Sickness and Death.					Absolute number constantly Sick, & dying annually, out of 100 living.			
Between Ages	20-30	30-40	40-50	50-60	Common Multiplier	20.30	30-40	40-50	50-60
Sickness Scotland	.57	.67	1.00	1.83	1.97	1.13	1.32	1.97	3.60
1 England	.60	.71	1.00	1.69	2.56	1.54	1.83	2.56	4.32
Deaths England	.51	.78	1.00	1.61	1.85	.95	1.45	1.85	2.98
Theory	.55	.74	1.00	1.43	-	-	-	_	

On inspection of the above table of exists a fixed proportion at every age relative sickness and death, it will be perceived that for the three decennial intervals number of deaths. If there are two years of age from 20 to 50, the coincidence of sickness to every death at any one age, between the theory and the observed facts the same proportion holds good for every is nearly perfect. Between the ages of 50 age; at least between the observed limits and 60 years there is an apparent, but no of 20 and 60 years. According to the real opposition. For according to the theory of mortality, a new rate of increase begins, or a new constant comes into operation at some variable age between 50 and 60 years. The above theoretical numbers are founded upon the assumption that the new constant comes into operation at the age of 55 complete years. If an earlier age (say 53) had been adopted, the theoretical numbers would have agreed with the facts for England. In the case of Scotland, we have no information respecting the contemporaneous rate of mortality. In England, the elevated ratio of sickness between 50 and 60 years, coincides with the clevated ratio of mortality at the same age. The establishment of this coincidence between the law of sickness and the law of mortality is the main object of the present remarks.

The fact being acknowledged, that the sickness suffered by a given number living, increases with the age, according to the

observation just made on English benefit societies, the constant proportion is that of one year and a half of sickness to each death at every age. From my own experience, I am inclined to the opinion, that two years of sickness to each death, is the proportion most generally prevalent. In the present inquiry, the exact amount of this proportion is a question of no importance; it is sufficient to know, that all observations (including a third unpublished extensive observation of mine) agree in showing this proportion to be constant at all ages.

Adopting as the the simple proportion of two years of sickness to the simple proportion of two years of sickness to the simple proportion of two years of sickness to the six obtain the following interesting come quences. If out of 100 living at anything at anything at anything at anything at anything at anything at the samuel as a fact, that the annual deaths will be two in numbers and reversely. If at any age, the proportion of sickness to each individual, amounts to the 25th part of same law which regulates the increase of a year, the mortality in one ray all amount mortality, it necessarily follows—that there to one in fify. If at any the mortality

The observation confidence might be reposed on the correctness of the relative results obtained from Under the age of 55, for every ten years this observation, more especially as they increase of age, the "Premiums for one mortality. But I entertained strong suspicions as to the correctness of the absolute results; and I felt persuaded, that the ON THE MORTALITY AT BACH AGE OUT OF absolute sickness therein expressed, was very much less than that generally prevalent in England. In my published health tables, English and Scottish observations, or rather Dr. Southwood Smith, Physician to the is that of the theory with which they so London Fever Hospital, which brings the nearly coincide. But I have adopted for the new theory of mortality, and the chief of its base of my tables, a number which is more three constants, in close apposition with than 50 per cent greater than that of the therapeutics and the practice of medicine. table of the "Highland Society," and 20 By means of this theory, whon the number per cent greater than that indicated by the lengthsh observation just published. The additional experience which I have since The reader may learn with some suracquired, has served to confirm the opinion prise that this new theory of mortality which I first hazarded respecting the ab- has been already extensively applied to solute sickness most generally suffered by practice, and has served as the basis of the English population. The results of my pecuniary engagements of great magnitude, theoretical tables do not substantially differ. For more than six years this theory has from the results of Dr. Price's tables of sick- | been the regulator of all the published lists ness, which have been in universal use for of prices offered by a London Life Insurance fifty years. But every two successive num- Company, as may be seen by the annexed bers in my tables, bear the exact same comparative table. The numbers in the relation to each other, which is not the case first and second columns are in the exact in Dr. Price's tables.

All my tables of life and health insurance in the third and fourth columns :-

charge other agreen by the constant of contacting together any two successive questions. For example, at page 28 of my "Life Tables," I have given the values at every age, of a life insurance of £100 for one year, deduced from the table of "Villes and the state of the contact of £100 for one year, deduced from the table of "Villes" the state of the contact of £100 for one year, deduced from the table of "Village Mortality," which is a theoretical table founded on Dr. Heysham's observation principles above explained. The observation at Carlisle. At the ages of 20 and 21, the of the "Highland Society" was at that values are .6529 and .6724 respectively; at time the only one extant, on which the the ages of 30 and 31, the values are 8757, graduation of sickness according to age and 9018 respectively. The reader will could be founded. I considered that great easily perceive that the excess in each case is measured by the constant 2.99 per cent. were in harmony with the theory of year" increase one third part, very nearly.

> A GIVEN NUMBER OF CASES OF SICK-NESS.

Within the last few days, I have met with the scale of relation is that exhibited by the an extensive observation lately published by

at any one age, the mortality at every age of life is also known. By means of the same theory, as I have proved above, the relative quantity of sickness suffered at each age of life is also known. The constant of mortality is identical with the constant of sickness: the same number which measures the increase of mortality according to age, measures also the increase in the quantity of sickness suffered by a given number of individuals. The new observation proves that the same constant, in the case of fever, measures the increase of deaths according to age, out of a given number attacked. It appears in the highest degree improbable that this number, of all others, should regulate the mortality in fevers, without being at the same time applicable to other extensive classes of disease. The materials for the decision of this question abound or ought to abound in all public hospitals.

The observation of Dr. Smith is founded upon 6000 cases of fever occurring during the ten years ending in January, 1834. subjoin the results in the form in which they have been published. I have added for comparison a column containing the numbers resulting from the theory, or from an increase of one third part (34.3 per cent) for every ten years increase of age.

Between Ages.	Out of 100 attacked by Fever, there die according to			
Delween Ages.	Fact.	Theory.

45-56	30.5	30.3		
5566	40.7	40.7		
Above 65	44.6	- 1		
		!		

The coincidence between the facts and the theory is sufficiently close to prove all coincidence had been perfect at intervals of five years of age. The theoretical numbers are founded on the assumption that the cases were equably distributed over each decennial interval of age, of which no evidence is presented. Dr. Smith has omitted to state the absolute numbers at each age on which his results are founded. The facts were probably very deficient in number at the beginning and at the end of his table; so that the results here are entitled to little confidence. The information would have been complete if he had given his materials distributed in quinquennial gradations of age. In the column of rges Dr. Smith has adopted an erroneous form of expression;

instead of " between the ages of 15 and 26." he evidently intended to say, between the ages of 15 and 25 complete years, which is the form generally adopted.

If it admitted that the aggregate of several distributions of the several distribution applicable between the limits of 13 and 60 years of age. That a given number living at every year of age suffer the same number of attacks of sickness; and that the duration of each case of sickness at any age, is proportional to the mortality at that age. The deaths out of a given number living, vary with the age, in precisely the same degree as the deaths out of a given number attacked; consequently, the proportion between the number living and the number attacked is constant. The proportion of sickness (in duration) to the number of deaths has been proved to be constant at every age. And since the number of cases of sickness (out of a given number living) at each age is constant, the average duration of each case must be proportional to the number of deaths out of a given number living, that is, to the mortality. Assuming that one tenth part of the living at every age are yearly attacked by sickness, the tacts above announced may be thus illustrated. If 1000 living at the age of 20 suffer 100 attacks of sickness, 10 deaths and 1000 weeks of sickness; then 1000 living at the age of 43, will suffer 100 attacks of sickness, 20 deaths, and 2000 weeks of sickness.

If it be confirmed by future observation, that diseases in general are subject to the same law as fevers, the knowledge of the new theory of mortality will form an indisthat is required. The small existing varia- pensable branch of medical education. (This tions might have appeared, even if the theory has been explained and applied in Nos. 605, 614, 640, 641, and 548 of THE LANCET.) Without this knowledge it will be impossible for a medical man to form any correct idea of the value of different remedies, when his patients differ in age. This theory will inform him that if he loses by death double the propertion of patients atthe age of 43 than at the age of 20, the et of his remedies in each rate is the same.

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY

TYPHUS FEVER IN THE YOUNG.

THE disease which French physicians are in the habit of describing under the various names of "typhus fever," "follicular enteritis," "dothinenteritis," "intestinal exanthema," has hitherto been observed with care in the adult subject only. The facts on which the works of ANDRAL, Louis, Chomes, and others, on this affection, are founded, were exclusively collected in bospitals dedicated to the reception of adults. For many years, however, M. Guersent, during the course of his lectures, has been accustomed to point out the existence of this disease amongst children, and the researches which we have ourselves made, leave no doubt on our minds but that typhus fever occurs very frequently after the age of ten years. It may, we know, even occur so early as at tour years of age, but we have never observed an example below the latter nee, although we have examined more than 200 subjects, aged from twelve months to three years old.

The symptoms which characterize typhus fever in children, are nearly the same as those which are observed in adults. There are, however, in the former some peculiarities which depend on the age of the subject, and which we propose to illustrate in the following cases. We would also call attention to the points of resemblance which this disease is supposed to have with certain anomalous cases of hydrocephalus. our own part, with all due respect to the opinion of some distinguished writers and practitioners, we must confess that we have never seen a case of typhus fever, however were which could be confounded with the "Yentoms of mante meningitie, or hydrocephalus. The distinctive characters of the two lust-montioned affections have always been so clearly marked as not to give rise to the least embarrassment or hesitation in

my a boy labouring under inflammation of the brain, in its most acute form. The physician diagnosticated typhus fever, and the error was not discovered before two or three days had elapsed, but here Mons. G. was led astray by a false history of the case, which he did not examine or in any way regard. The slightest examination of the patient would have been sufficient to reveal the true nature of a disease which was so little obscure as to be diagnosticated by the nurse.

The treatment pursued by the physicians of the hospital Des Enfans varies. Mossicurs Guersent and Japelot still continue BROUSSAIS' method, and employ sanguineous emissions. M. BAUDELOCQUE prefers the purgative method, by Seltzer water in particular. Blisters to the legs and thighs are very frequently had recourse to, and bark is occasionally given, either by the mouth or in lavement, in the adynamic form. In cases of ataxic fever, baths, with cold effusion on the head, are a favourite remedy in the hospital.

Case 1 .- Louis Haquelle, 9 years of age, of a lymphatic temperament, hair light-coloured, skin white, &c., generally enjoys good health. He has been in Paris only tive months, and lives with his mother and brother in a small chamber, ill ventilated, and unwholesome. On the 1st of September, without any known cause, he experienced a sensation of uncomfortableness. with loss of appetite and headache. These symptoms persist during the four days that follow: however, the child continues to go to school, but on the 5th he is seized with continued fever, excessive headache, accompanied by ringing in the ears, complete anorexia. The child was now confined to bed, and placed upon diet. On the 6th an abundant epistaxis. On the 8th the patient was received into the hospital.

On the 9th we examined the boy for the first time, and observed the following circumstances :- Position of the child is relaxed, he lies on his back; great prostration of force; immobility of the countenance; face pale; answers slowly, but correcty, if the attention of the patient be fixed by any particular question; frontal headache; ringing in the cars very troublesome; the lips are dry, and covered with a crust; the tongue red, smooth, and dry; thirst very great; no vomiting or nausea; the abdomen is sonorous on percussion, and tender when pressed upon, especially about the umpilical region; no stools since his reception into the hosthe mind of the physician. Once indeed skin warm and dry; pulse 108; inspirations (and we shall expost the case at length) we 36; cough pratty frequent; the sonority of the cheet is normal. We he rale on both sides.—Asidulates is mal) 2 jugs; 8 lecches round the emollient cataplasm to the leach ment ; diet.

In the evening, exacerbation of the febrile movement; deligium, which continues dur-

ing the night.

10. The agitation of the night previous has been followed by a deep prostration; somnolence; stupor; eyelids closed; the force and frequency of the pulse have fallen; pulse 96. The leeches have drawn a great quantity of blood; no active treatment is employed.

11. The evening and night have been found in a still higher degree of agitation; October (the day of the patient's death), the patient left his bed several times, and it gangrenous eschars were formed on both was necessary to employ the strait-waistings, and on the cibox, as also at the coat; in the morning, alternations of agitation and prostration; the child cries when plied. The leach bites have become the ever the hand is applied to the abdomen, or seat of deep ulcerntion. The tunefaction any other point of the skin; two stools, one of the left parotid has subsided, but a purvery liquid; we now perceive some lenticulant fluid is discharged from the cars; the lar rose-spots on the abdomen; the cough pulse remains feeble and compressible; the dies the same as before, except leeches.

notice.

13. During the night a very abundant involuntary. epistaxis, followed by excessive prostration. The wounds are dressed with a pommade On the 14th, we find the patient still deli-containing bank; the ether draught is conrious at the morning visit; he is exces-tinued: a lavement of quinine given, and a sively agitated, and cries out constantly; it few spoonfuls of claret wine by the mouth. is with difficulty that we can count the The patient died on the 2nd of October, pulse, which is 132; venesoction was imme-in the most extreme degree of marasmus diately practised at the arm, and about five &c. ounces of blood taken away; the clot is soft; no trace of inflammatory crust.

15 and 16 The ataxo-adynamic symptoms are more prominent; the patient does parchment; pulse excessively feeble, varies from 112 to 120; temperature of the skin not much elevated; one liquid stool a day; the abdomen is tympanitic. Tepid bath, with cold affusion on the head; four ounces of an emollient draught; sinapisms to the legs.

17 and 18. The same remedies are continued. The patient is pretty calm; he

quent; the child has no diarrheea.

20. The patient lies nearly in a state of coma; the eye is fixed and dull; the cyclids half open; the papils dilated, but contractile; he does not answer when spoken to; emission of arine involuntary. The tongue and teeth covered with a dark crust; deglutition difficult; sensibility of the skin is now obtuse; pulse 118, small, irregular, to the disphragm by a pseudo-membranous A blister to each leg.

uty immoveable. A levement of id: two blisters to the last. efaction of the left parotid , somore; prostration the same;

24. The 2.05

complete loss Conscion utters a few feeble cries when he in bed; exceriations on both thighs, on the sacrum, and over the right elbow; the arms are raised up from time to time; the extremities are cold; pulse weak and very compressible, 112. Ether Draught; Lavement of Bark.

From the 28th of September to the 2nd of persists; pulse 112; respiration 36. Reme- skin almost cold. The patient remains in a state of absolute silence, though on the 12. No remarkable change worthy of 29th he seemed to recognise his mother. The diarrhoea is abundant, and the stools

Examination of the Body Eighteen Hours after Death.

The body is extremely emaciated; large not answer a single question, and is unable superficial ulcerations occupy the right to recognise his mother. The lips are elbow and both thighs. There are a few cracked, and furnish a sanguineous exudation; the tongue is dry, like a bit of the chest; cadaveric rigidity very well marked.

Skull .- Dura mater normal. The occipital fossa contains about two spoonfuls of fluid and clear serum. The arachnoid every where presents its normal colour, and is easily separated from the subjacent parts. The pia mater offers no other change than a slight scrous infiltration; the substance of answers some few questions, and does not the cerebral hemisphere is moderately inseem to suffer any pain. Still the tongue jected; when divided into three slices, we continues dry and dirty, and the pulse fre- find no trace of ramollissement or other morbid change. The central parts offer their normal colour and continuity. The cerebellum is more pair and more far the cerebrum. The point will normal the cerebrum. The point will normal their normal than the colour trades, and broach.

are pale, and lined with mucus; the bronchial glands normal; the two lungs are pale anteriorly. The base of the right lung is united blister to each leg.

21. The stupor persists; the pupils are we find a portion, about the lung of an apple, which has passed to a state of partial patiention; the two other lobes are bridged they contain but little blood; and let they rior lobe, in partially "like they be stated they be been partially "like they be said faccid, of a march of the heart a pleasant faccid, of a march of themses of this sorts does not present any change of colors."

Abdomen .- The anterior wall of the stomach (internally) offers a patchy injection: the remainder of the mucous membrane is pale, and of normal consistency; the dnodenum is tinged with bile; the jejunum and two upper thirds of the ileum are pale; in the inferior third of the latter intestine we observe no less than twentyseven ulcerations, occupying indistinctively the glandulas agminate and segregate; these ulcerations are superficial, and merely involve the mucous tissue, which is soft and injected for the extent of about twelve inches near the cacum; the ileo-cacal valve is riddled with ulcerations: the mucous lining of the cacum presents a livid colour, and is remarkably thickened; the glandula regregatar of the colon are very apparent, and marked in the centre by a dark point; n the intervals the mucous membrane is sale and of good consistency; the mesenæric ganglia are not more developed than n the normal state; two or three are of 1 livid colour, and rather hardened than oftened; the spleen, which offers its ordisary volume, is a little less firm than natural.

CASE 2.—François Chevalier, 4 years of age, was carried to the hospital Des Enfans Malades, on the 5th of November: he persons by whom he was conducted noton us that the child, who was convalescent from the hooping-cough only a few lays, while on the route from St. Omer to 'aris, was seized with vomiting, diarrhora, and fever; these two latter symptoms peristed for five days following the attack, and on the evening of the fifth day were accompanied by prostration and some convalsive movements.

7th. Position variable; alternations of rostration and of agitation; stupor; low ries now and then; the child does not unswer; the cyclide are half open, and the mylle are normally dilated; the sensibility of the skin is not changed; the lips are dry not cracked; the tongue dry and red; the hirst employe; the abdomen tender and yis parties; the abdomen tender and yis parties; the first employe; the abdomen tender normalised by the state of the leuticular rosepots; the state of the country; kin warm and thy; pulse very quick, about 40; cough rare, accompanied with a râle ibiliant at both sides of the chest. Game

braught; singuious to the leys; diet.
The same graptoms persist during the lays of the hand sth; we cannot observe my convolute movement, or change in the

The same of the state of the state of

citameous smalbility; the child does not recognise his parents who come to see him, and continues to atter low cries from time to time; the sense of hearing is obtuse, and that of sight seems perverted. The evacuations are still frequent and involuntary. The pulse varies between 136 and 140. On the night of the 8th the child fell from his bed in an access of delirium; in the morning we find the right check blue and excessively tumefied; the lips and gums furnish a sanguineous exudation; the tongue is very foul and dark; the pulse is every foul and dark; the pulse is every foul and dark; the pulse is every foul and the state of support the persist. The little patient sank in the evening of the 9th in a state of stuper.

Post-mortem Examination.

Ekull.—The versels which run along the surface of the brain are evidently injected. The arachnoid membrane retains its normal transparency, and is easily detached from the convolutions, the sub-arachnoid cellular tissue is very slightly infiltrated with serum; the pia mater does not contain any granulations or purulent secretion. Three ounces of serum at the base of the skull; one ounce in the ventricles; the cerebral substance itself is quite free from injection. No trace of tubercles or ramollissement.

Neck and Chest.—Larynx and trachea normal. The bronchial tubes are gorged with mucus. The right lung adheres to the parietes of the chest for an extent of about two square inches. We observe a few gray demi-transparent granulations underneath the pleura covering the lungs. Both these latter organs are congested in the posterior part: the bronchial glands contain tubercular matter.

Abdomen .- The mesenteric glands are a little augmented in volume, of a rosy colour. The spleen is enlarged, but its consistence is normal. Liver healthy. The interior of the stomach is marked by numerous folds, whose edges are red. The mucous membrane, however, is free from softening; the membrane lining the interior of the duodenum is remarkably pale; the same decolorstion exists in the jejunum and in two-thirds of the ilcum; the glandulæ segregatæ are here very much developed. In the inferior third of the ilcum, we count about twenty groups of an oval form, injected and prominent; three, placed near the ileo-cæcal valve, aro ulcerated partially. The membrane lining the great intestines is furnished with a great number of follicles not ulcerated, but presenting a moderate degree of injection and slight diminution of consistence.

We will add some other cases, and attach to them some remarks in our next number.

CABE OF

ANEURYSMAL TUMOUR IN THE

SUPERVENING INJURY OF THE READ, AND TREATED BY

LIGATURE OF THE COMMON CAROTID.

To the Editor of THE LANCES

Sin,—I should feel obliged by the institution of the following case in your publishin. If not too long, I think you will consider it sufficiently interesting. Having omitted all details of treatment, which was that usually pursued in similar cases, and having confined myself to an account of the principal occurrences, I am not aware that the history could be advantageously curtailed. I have the honour to be, Sir, your obedient servant,

George Busk, Surgeon to the Seaman's Hospital. H.M.S. Dreadnought, Feb. 19, 1836.

Richard Simmons, aged 20, a seaman, was admitted, July 13, 1835, labouring under the usual symptoms of concussion of the brain, with very considerable hemorrhage from the right ear, and a small wound behind the left. It was stated that he had received a very severe blow on the right side of the head, from the gaff of the vessel to which he belonged, by which he was rendered immediately insensible, and he was nearly so on admission, and could with difficulty be roused. At first he was very pale and cold, but in an hour or two he ral-lied. The hemorrhage from the right ear continued all night. On the following day he was quite sensible, but appeared dull, not complaining of any pain; pupils natural. On the 15th he was still dull, and completely deaf in the right car. The cyclids, and the integuments around the left orbit. were swollen, apparently from serous effusion; they were not discoloured or painful. The pupil of the left eye was dilated and fixed, vision however was unimpaired, but he was unable to move the globe of the eye in any direction, and had slight paralysis of the facial muscles on the left side.

On the 18th some increase of inflammatory symptoms required attention, but was readily subdued. The pupil was observed to have become irregular, the irregularity, consisting in an elongation downwards, and vision was not quite clear; there was seen-sionally a very partial rotatory motion of the globe, as if caused by the apparently involutary motion of the superior oblique muscle. He had some headache, confined principally to the left side.

On the 21st his mouth became slightly

affected, by mercury. On the 24th the heating was very triding, but the left side of the state o

able purulent districtings from the conOn the 25th the integuments of the first side of the face and head, extending to the vertex, were extremely tender to the tench, but without any morbid appearance. The continued unaltered on the 28th, the transported and the 18th the continued unaltered on the 28th, the transported from cedematons effunction, and on the 31st purulent matter was the posited between the lamine of the correct state of the cor

He term spot to complain of curious noises in the feet car, from which the discharge continued, and he was very deaf. The eye was not painful but the onyx was increased. In the beginning of September the paralysis and loss of sensibility were complete. The anterior lamina of the cornea had given way, and a deep ulcer occupied the site of the abscess, of a healthy character. No change of importance took place until about the 20th of November, when he became affected with small-pox, and was sent to the Small-Pox Hospital,

whence he returned on the 1st of December. On his readmission the state of the face unaltered; the eye generally was prominent and much inflamed, the ulcer on the cornea was large and in a very irritable state. The severity of these symptoms was soon pretty well subdued, and attempts were made by counter-irritation in every form, and other means, to remove the palsy of the face, without effect. Sensibility in some measure returned, preceded by anomalous painful feelings in the affected integuments. He continued in this state without any change in symptoms or appearance, except that the eye seemed to pro-trude rather more from the orbit than had been previously observed. The ulcer on the cornea filled up

His general health being quite restered, and medical treatment not appearing to have any effect, set file local complaint, he was desired effects of the local complaint, he was desired effects of the country and trust treatment of the country and trust treatment of a state. However, on the lated force of acture. However, on the lated force of acture. However, on the lated force of acture. However, on the lated force of the country on the late of the country of the co

of the loose conjunctive.

The substitution of the sumour panied by a very defined Pating could also be felt on the last the part in its immediate moighbourists. Through the stellar and the part in the stellar and th alse be heard in applying the instrument over the inner canthus of the other eye, and on the left side of the frontal bone, a large the roots of the hair, and nearly in the on the left side of the mount as the roots of the bair, and nearly the said the said to be a sai back as the ear. He has very har collect in the head in the right ear, resembling the sound of church bells, and in the left like the breaking of waves on the sea shore. He complains more of these incessant noises than of anything else.

Operation.—As pressure on the fall com-mon carotid put a stop to the paysation and sound of the aneurysus, and to the noises in the head, it appeared to me that the placing of a ligature on that vessel presented ground for hope, and perhaps the only hope, of affording him relief or even permanent cure. As a preparatory step, he being very well able to afford the loss, twenty ounces of blood were taken in the evening, and, on the next day, February 2nd, the left common carotid was tied. Immediately on tightening the ligature, the pulsation and sound of anenrysm ceased, as also did the internal noises.

In the evening, four hours after the operation, obscure pulsation could be felt in the tumour, which, however, was not so large. The whizzing sound could also be plainly heard with the stethoscope, and over as large an extent. There was no pulsation in the temporal artery. The internal noises were at intervals nearly as loud as before the artery was tied, and at others nearly absent. He felt great pain on swallowing; pulse 110. He took 5ss of Liquor. Opic Sedatir., and a wetted cloth was applied to the forehead and eye.

Feb. 3. In the morning, the pulsation was very obscure, and the sounds much di-minished. The internal noises were also much less. He had had no sleep, and complained much of pain on deglutition, and on coughing, and of severe pain in the left hypochordrigum. He has also a very trouble-some cough, which he has had for some time. Pulse 120, sharing lie was blocked for a with immediate will and in the

the stethostopy. The internal notes and in the evening was much easier in all respects.

It is not the property of the tumour could be could, nor spirit new sound be heard with the stethostopy. The internal noises are quite absent, and his hearing it somewhat improved. Pulse 100, soft, skin moist, and tongue clean. The pain had left the left slight hemorrhage isning from the mouth. hypochondriam, but he felt some he the In the beginning the saliva was only tinged right whereant ting. The wound was dress-with blood, but, soon afterwards, pure blood ed, and the left were removed; adion ran out uninterruptedly. Common renedles

cyclid was raised, it caused some projection had taken place to a great extent. In the evening the cough was occasionally severe. with mucous expectoration, and and rolerreu to the disphragm. Pulse 129, soft, skin moist; bowels not opened. He had some calomel and compound was of colocynth, and a mixture with sulphate of magness and tincture of digitalis, and a linctus for the cough.

5. Be felt very comfortable; has had seless prominent.

or Foots weak, but is quite free from pain; could acarly gone. The conjunctiva is much less vascular than before the operation, and the cornea is clearer. Some grumous blood was discharged from the left nostril during the night. Pulse 90.

7. Pulse 80. The lips of the wound are opened, but it is filled with healthy granulations; sleeps well; appetite too good.

Il. He sat up several hours, and on the

15th, the ligature came away. 18. The wound is all but cicatrized; he is quite free from pain or uneasiness; feels only hungry and weak; he is not yet allowed meat; pulse 70, soft. No remains of the ancurysm can be detected; the eye is returned wholly to its natural level; the upper half of the cornea is quite clear, the lower is occupied by a dense leucoma, to the centre of which runs a large red vessel from the conjunctiva. That membrane is hardly vascular, and vision is good through the clear part of the cornea when the lid is elevated ; the pupil natural. The left side of the face is paralyzed, but sensibility is perfect except on the left side of the nose, where he feels pricking pains when touched. He has no power of motion whatever over the globe of the eye, and is still very deaf, and more so in the left car than in the right, but has no noise in the head. His intellects have never been affected. Pulsation is very distinct behind the lower portion of the sternocleido-mastoid muscle, probably in the subclavian.

If any change of consequence takes place. while the man is under my care, I will take the liberty of communicating the particulars through the medium of this journal.

CASE OF

HEMORRHAGE FROM THE MOUTH. By Julius Wolff, M.D., Liverpool.

D., the commander of a vessel, twentyfive years of age. of robust constitution, being in good health, was attacked with a

were applied, without success. He then stopped for thirty-six hours, and then began sent for his physician, who ordered astria- again with renewed violence. During this gent gargies, and the second of the second safterwards another physician was consulted, began into a recovered a little, but who ordered venesection, astringents to be in the chef, and immess of state. In the chef, and the continued of patient went on for a fortnight.

blood ran uninterruptedly out of his mouth, tea, with eggs, which was poured with teaand I could not discover the source. The spoons between the lips, and was swallowed patient did not complain of any uneasiness besides, but was much alarmed at the great and constant loss of blood, and durst not any cause. The patient was of a plethoric habit, and had frequently had bleeding at the nose, which was always difficult to be checked. I ordered a venesection, and a warm foot bath, and during the bleeding the hemorrhage ceased, the astringent remedies being continued. About an hour afterwards it began again.

I now saw distinctly that the blood came from the roof of the mouth, and from a small spot of the gingiva, near the third lower molar tooth. I proposed to touch the part with nitrate of silver, and to extract the third molar tooth. The former proposal my colleagues accepted, but the latter they objected to. After the application of the nitrate of silver, the bleeding stopped, but a quarter of an hour afterwards it began again. The patient's face was pale, and the pulse small. Other complaints, which generally attend such great losses of blood, were not present.

I was now determined to extract the tooth; but on account of the blood which gathered so rapidly, I could not see the lower set of teeth. I caught a tooth in the region where I suspected the blood to come from, and after I had extracted it, the bleeding stopped. I filled the socket with wax, applied mustard plasters to the soles of the feet, and the before-mentioned medicine was continued.

The patient slept for a few hours, and recovered a little. Eleven hours afterwards Hahnemanist. What an effect would the the hemorrhage began again. My colleagues 24th dilution of a grain of aconit napel have had by this time forsaken me, and the case being now left to my sole care, I had him placed in an arm-chair, and applied uninterruptedly every two minutes fresh ice to his cheeks, and let ice melt in his mouth, and soon afterwards the bleeding was checked. The room was kept as cool as possible, and the half-sitting position in the arm-chair and the application of ice were continued. From time to time the warm warm that the was put on low diet, and I gave him decoct, crystal tartar, c. syrup, rib., for a drink. The hemorrhage had by this time forsaken me, and the case produced here? or the quintillionth or the

mouth with wax in such a manner that the January the 20th, 1835, at nine o'clock in air could only go through the nose, and by the evening, I was sent for. I found the means of a bandage which I applied, nest patient sitting in bed, his face flushed, and the pulse full, but not very frequent. The The nourishment of the patient was beefvery well.

After ceasing for ninety hours, during which time the patient recovered a little, move. I could not trace the hemorrhage to the bleeding began again very severely. I now had recourse to the actual cautery, touching the socket of the tooth, and the whole roof of the mouth, until the bleeding stopped. In twelve hours it began again, but the cautery being repeated thirteen times, it was finally checked. The scab caused by the iron came off after the roof had obtained a new integument.

Mr. D. bore all this with admirable pationce, though the frequent return of the hemorrhage dejected him sometimes. It had lasted now, with the interruptions stated, for more than five weeks, the shortest intervals occurring in the first fortnight. The patient was kept during more than six weeks in the half-sitting position in an armchair in a cold room, where uninterruptedly the application of the ice and the astrin-

gent medicine were continued. After these six weeks, I allowed him to sleep in his bed again, but in a very cold room, I gave him acid. sulphur. dilut., and, afterwards, serum lactis alumin. (consisting of lactis vaccini, libram unam, ebulliat in vaso figulino; dein adde aluminis drachmam unam; colatura D. S., for a drink); ordered proper diet and rest; afterwards, proper exercise in the open air, and on the eighth week of my treatment Mr. D. visited his friends again, after having been reported frequently to be dead. A few months after he recovered the red bloom of his face.

In such a case I should like to consult a

and the last and the second of the

subject the following remarks:—The mether oil of rock, and was so called because it was of Mr. D., 62 years of age, of robust con- distilled from a mineral. Mr. Osborn, howstituton, experienced the cessation of men-ses 6 years ago, but was natil that seriod always regular, and the opinion. When young the discussive under from hemor-rhage. The nose. In the month of February are suffered from a very severe inflammation in her throat. I ordered leeches, but the surgeon refused to apply them. (There is in Germany a lower class of surgeons, who apply leeches, bleed, etc.) When I asked him the reason, he told me that he was " afraid that he might not be able to check the bleeding, because be knew from experience that it was not an easy matter to check a bleeding in this lady But he did not object to a venesection. He opened a vein, and I applied two leeches on the sternum, in order to convince myself of what the surgeon had stated. The wound of the vein bled for many hours after a bandage was applied, and I was obliged to make a strong compression before the desired effect could be produced. To the leech-bites constant compression, and many other remedies, were applied, yet eight days afterwards a little blood was now and then yielded.

Mr. D.'s sister, about 30 years of age, tall and stout, had had three children, and suffered, when young, frequently from bleeding at the nose. Her menses were regular, and not copious. When brought to bed, her loss of blood was not uncommonly great. She assured me, that a few years ago she cut her finger, and lost such a quantity of blood, that she fainted several times, and the hemorrhage was stopped only with very great difficulty.

Mr. D.'s younger brother, who frequently suffers from hemorrhages of the nose, had a molar tooth extracted. The bleeding was not stopped until the third day arrived, and repeated application of the actual cautery had been made.

Neither Mr. D.'s father, nor his elder brother, was liable to hemorrhages, but this tendency existed in the family of his mother, several of them having suffered from it, one of them a few years ago really dying from hemorrhage. The disposition is therefore inherited from the mother.

94, Duke Street, Feb. 1st, 1836.

MES ON ME. OSBORN'S LITALS OF BLOOD.

Sin, In THE LANCET for Feb. 20th there is a paper by Mr. Osborn, chemist, of The above, or "Petroleum in the Blood." introduced into a quart bottle the bulk of The above, detection somewhat surprised the retort into a sand-bath, which was me, as sentition really means a spirit or placed in a charcoal furnace." When ana-

ever, calls it a peculiar kind of petroleum, but fails, I think, to show that it in the least resembles petroleum in its character and properties. The first test which he made use of was that of touch, the second that of smell; the one was disagreeable, the other adhesive. If this he precision, then indeed chemistry is a superficial science. He next says, "it is soluble in alcohol, and turns of a THICK brownish white colour, when well mixed with water. By evaporating the spirit, the tar again floats on the surface." Of what? He does not say, neither does he tell us, whether it is the alcoholic solution of the tar or the tar itself which turns of this strange colour. He says very little else about its chemical and physical properties, except that "it burns like common tar (not like petroleum), leaving a smell not unlike that of burnt feathers." The smell of burning animal matter is much alike in all cases. He then ("the quantity obtained being too small for redistillation) heats a little in a bulb glass, to the temperature of ebullition, when a spirit was given off, which took fire when brought in contact with a lighted taper." What the temperature of "ebullition" is he leaves us in the dark, and how he can call that a "spirit" which might have been a gas (for he never condensed it. even if it were the vapour of a spirit). I am at a loss to determine.

The process made use of is most incompatible with any correct mode of searching for a minute quantity of matter in any body, and at the same time shows a want of knowledge of chemical equivalents which is quite at variance with his title of "chemist." begins, without any visible object in view, by adding "an ounce of concentrated suf-phuric acid to each pound of blood (of which he takes eight pounds) before separation;" which he allows to stand four-andtwenty hours, being frequently stirred; to this he adds for each ounce of sulphuric acid, two ounces of carbonate of lime, but why he was so liberal of chalk does not anpear, as equal weights, or at any rate a very slight quantity more in weight of chalk than of acid, would have formed a perfectly neutral salt, forty-nine parts by weight of oil of vitriol uniting with fifty of carbonate of lime, they being as nearly as possible equal weights.

Now as Mr. Osborn was working for proportions, as he afterwards states he was, he appears to me to have gone in a very clumsy way to attain his object: he makes use of "an earthenware retort" (capable, of course, of holding eight pounds of blood) having its beak lengthened with "a tin tube three feet long, the extremity of which was lysing for proportions, it is customery to with an important medification, which modi-use apparatus of glass to prevent conta- fluiding Dr. Williams asserts, in the paper use apparatus of glass to prevent contamination or loss. That Mr. Osborn cannot have had sufficient practice to entitle him to make and publish an analysis of the him to make and publish an analysis of the statements, is a think, from these statements, apparent; and as far as I am capable of his denoter view, that they will be much judging, he appears to have obtained were muscular sounds. Do, William Balan, nothing but the well-known animal oil of Dippel, as the substance, so far as can be gathered from his description, appears to resemble it in its characters and in matter.

I should not have intruded invself on the notice of your readers, but that I have observed lately a great number of persons, attempting an analysis of the blood, who have no pretensions to a scientific or practical knowledge of chemistry. Hoping that this analysis of Mr. Osborn's paper will obtain a place in your valuable and equitable journal, I remain, Sir, your obedient ser-W. C.

Brompton Square: February 22nd, 1836.

REMARKS

ON

DR. WILLIAMS'S RECLAMATION

RELATIVE TO DR. HOPE'S LATE EXPOSITION

OF THE

SOUNDS OF THE HEART.

To the Editor of THE LANCET.

SIR,-The perusal of some remarks by Dr. Williams on the newly-adopted opinions of Dr. Hope, in the Medical Gazette of September 12, 1835, to which my attention has just been directed, has induced me again to request of you the favour of a place in THE LANCET for a few observations on the heart's sounds.

In 1832 I forwarded to THE LANCET a paper containing an explanation of the heart's normal sounds, the correctness of which has been partially, and, I have little doubt, will, sooner or later, be generally adopted. Very similar views had, I have since found, a short time before been advanced by M. Rouanet, at Paris, in an inaugural thesis, and, previously to this, brought forward by Dr. Billing, when President of the Hunterian Society, in a paper rend at the annual meeting of that Society in 1832.

These views were then new, and opposed to the opinious of all other writers on this subject. The views of M. Rouanet and myself with regard to the heart's second sound, have been quoted and adopted by Drs. Hope and Williams. The explanation of the first sound, however, as given by M. Rouanet, has been adopted by Dr. Hope of the resistance, trings a

mentioned, is nothing more for less the plane or had explanation, first pub-lies of the property of the cheet in amongst others, the following remarks

"Dr. Hope, in his work published in 1832, ascribed both the first and the second sounds of the heart to the collision of the particles of fluid; and, until the publication of the "Appendix" in April last, he had not, in his several writings on the subject. expressed any distrust or qualification of his original opinion."—(These views, be it remembered, were, at one time, adopted by Dr. Williams, but they met with a complete and unanswered refutation by me, in a paper and examered refutation by me, in a paper in The Lavors of Sept. 22rd, 1833.)—Dr. Williams continues.—"Here, however, he comes to the signature of the signoid valves, and single first is compound, consisting, first, positive cleare of the signoid valves, and single first is compound, consisting, first, positive of a loud smart sound; secondly, of a loud smart sound, produced by the abstract act of sudden jerking extension of the muscular walls, in the same way that such a sound is produced by similar extension of the leather of a pair of bellows; to avoid circumfocution, he calls this the sound of extension; thirdly, a prolongation, and, possibly, an augmentation of this sound, by the sonorous vibrations peculiar to muscular fibre."

The same experiments which led Dr. Hope to adopt and modify the opinion of M. Rouanet as above, led Dr. Williams to the following conclusions: - "That the first sound is not dependent on the closing of auriculo ventricular valves is evident, from five observations in which the closure of these valves was partially or completely prevented, yet the first sound continued.

I have here to remark that the experiments referred to, as detailed by Dr. Williams, were not conclusive in favour of his view, but the contrary; for we have it on the authority of Dr. Hope, that the partial impediment to the action of the valves produced an equivalent alteration in the intensity and clearness of the heart's sounds.

These remarks are also at variance, with the following, which occur in the next

"If some of these circumstances be re-moved, as in my experiment, there the resistance of the colors for the property was taken away, the something that the be heard in the dollar, and a subdured character of common muscular sound. Probably, in common pulsations, the ventricles sonorus until the closing of the application that is valve; this closing of the application of the resistance, brings and the resistance, brings are the contraction of the resistance, brings are the contraction of the resistance.

te muscular tension, which continues us if contained in any of Dr. Williams's previous te contents of the ventricles are sufficiently contained of the heart's sounds, nor that typelled. This accounts for the heart's sounds, nor that typelled. This accounts for the heart's sounds, the content of the heart's sounds, but I think the reader of suggests flow the day of the will perceive that all the above explanatives contributes to its clearness. The strictles will perceive that all the above explanatives contributes to its clearness. The strictles of the contributes in the contribute of the contributes of the contrib apping commencement of the bridges, apping commencement of the bridges, apping commencement of the bridges, and alves contributes the distribute of the aricular values, the chorder bridges, and re insecting above of the ventricles; if shoy ie income, abres of the ventricles, if they sterior of the ventricles, may have an equal hare in the production of the first sound; ut I am disposed to think that what we car proceeds chiefly from the contracting enseness of the external walls of the heart. oth because they are nearer to the car, and ecause, in one observation, the contraction f the left ventricle upon my finger within ; was by no means so abrupt or strong as hat of the exterior, as felt by the other and, and still heard through the stethecope.

I cannot conceive how Dr. Williams can uestion, whether or not the littless attain degree of tension equal in the of the mus-ular substance of the periodic late. In a pa-ser, in The Larger of Jan. 12, 1832, I have h monstrated that the valves must attain a me abrupt and a greater tension than the ubstance of the ventricles, and I feel confibut that Dr. Williams's acquaintance with thysics would, after a short consideration on he point, lead him to the same conclusions. ir. Williams should remember, that his lager trammelled the action of the very alve whose degree of tension he assumes t to have measured. The ingenious argumats, in the latter part of the above quoation, appear to me to involve a petitio wincipit; they certainly do, if Dr. Williams vould wish to infer that the first sound is 10t of valvalar origin, because the sound read by the ear, is that occurring in the 'xternal fibres of the ventricles; for, the prestion is not, Where are the vibrations? out, What is the cause of those vibrations?

Again: "The cause of sound is resisted notion; and the strongest and quickest moion, most abruptly and forcibly resisted, will give the loudest sound. Hence the entricles, rapidly contracting from their laceld state, give most sound when their notion is first resisted by the mass and weight of the blood within them, which is confined within the auricular valves.

And when I would ask, is the motion art; resisted." Why, when the valves does And when is the blood "first conbust." Why when the valves does. And when is the blood "first conbust." Why want the valves close. Ergo, r. William is the blood of the blood pears to me to he a decided non sequilur. Dr. Williams further argues, that the above

The same of the same of the same of the same of

per to which Drs. Williams and Hope have referred, and from which the following quotation is taken:

"And fissible solid, suddenly brought from state of relaxation to a state of tension, vibrates, and its vibrations are sonorous or not-i. e. audible or not, according to its physical structure. At the commencement of the systole of the ventricles, their auricular valves are flapped into play, and, at the instant of their closure, the whole substance of the ventricles and the valves are suddenly brought to a state of tension, and then, consequently, they vibrate. I leave it to the reader to determine whether the vibrations of the valves, or of the muscular substance of the ventricles, would most contribute to the formation of the first sound.

The objections advanced by Drs. Hope, Williams, Bouillaud, and other writers, may be valid, and may apply to the theory of M. Rouanct, but they do not apply to mine. I remain, Sir, your obedient servant,

E. L. BRYAN. Stowmarket, Feb. 23, 1836.

GERMAN JOURNALS.

Press of matter prevents us from passing in review all the articles contained in the last numbers of the German journals which we have received; we shall, therefore, content ourselves with an enumeration of their contents, and a brief notice of the most important papers to be found amongst them.

Hecker's Annalen, Vol. II. Nos. 3 and 4; and Vol. III. No. 1.

1. On the Influence of Trades and Professions on the Health and Mortality of a Population. Part 1. By Dr. Fuchs. shall wait until the second part is published before giving an account of this interesting memoir.

2. On Gastro-enteritis. By Dr. KORLER of La Charité.

3. ON SCARLATINA.

By Professor LICHTENSTADE of Berlin. St. Petersburgh.

This is a long memoir, containing an ac-Drew Missons further argues, that the above three eightenesters to have a tong memors, containing an action table three eighteness actions are allowed in the columnic scarlatina which present a construction of the columnic scarlatina which presents a constaining and the columnic scarlatina which presents a constaining and disease which the columnic scarlatina as a disease which is eminently contagious; he cites several ance, especially for the diagnosis of scarle-cases, where it was transmitted from house that: We have almost invariably observed to house through the medium of visitors, who themselves remained unaffected; however, by using proper precautions, he was always fortunate enough to avoid the danger. The period of contagion is often protracted to a very considerable length of time; the professor was accustomed to consider six weeks as the maximum, but during this epidemic the disease was evidently transmitted from one individual to another, at the distance of eight weeks from the commencement of the attack; a long-continued exfoliation of the epidermis seems to favour the prolongation of the contagious period. The only method of checking the disease, is to avoid as much as possible all circumstances by which its contagious property may be propagated. Dr. Lichten-stadt has experimented with belladonnaa remedy much praised latterly as a preventive, but without any good effect.

The march of scarlatina may be divided into three periods; that of invasion, that of eruption, and, finally, the period of desquamation. The first rarely lasts beyond twentyfour hours; as a general rule, it may be laid down that the disease is dangerous in proportion to the shortness of the first period; however, this admits of several exceptions.

The second period, or that of eruption, lasts usually from seven to nine days, unless it is cut short by the child's death. In the latter case it may terminate in eighteen hours (one example of which kind the author observed), or in thirty-six hours after the commencement of the period. The colour and extent of the eruption are very various. Some writers advance that a deep red colour, uniformly spread over the whole body, is a favourable sign; on the contrary, the author thinks the danger is always increased in proportion to the intensity of the cruption.

The pulse, as is usual in this disease, was always quick, and not reduced by the appearance of the cruption; at 100, it was not an unfavourable symptom; the pulse often rose to 120, and this also without indicating any great danger; but the disease was always the more grave and fatal, in proportion as the pulse exceeded this latter degree

of frequency.

Bloody evacuations were sometimes observed during the course of this period, but they did not seem toexercise any remarkable influence in its march or termination; several children were seized with epistaxis, some recovered; others died. One patient, who died on the fourth day after copious loss of blood from the nose, was seized thirty-six hours later with violent hemorrhage from the vagina. The indications rhage from the vagina. The indications of the variety of the variety of the united of the united of the Administration of the united of the Administration of the variety exercition, do not present anything remarkable. The state of the tongue of the tongue of the variety of th

shee, depocially for the diagnosts or sense-tion. We have almost invariably observed the red, developed papille, at a very early single, horizing, the author, says, in the present spinishme, for the fight few days after the appendix of the semption, the tongue was covered with a whitten the re-white far, by no means characteristic of acartatina, and not differing from that observed in common fevers; however the anterior portion and edges of the tongue gradually assumed a reddish colour, which soon acquired the true scarlatina tint.

Some cases of gangrene of the fauces were observed, but the author saw hardly any example of the diphtheritic inflammation.described by BRETONNEAU as extending to the pharynx and larynx. In one case this gangrenous inflammation was complicated with croup. In several cases also, especially towards the end of the epidemic, the author observed a ringing cough excessively like croup, but all these terminated favourably. The duration of the desquamating period is various. In some cases the desquamation was not completed six weeks after the commencement of the disease; in others it was still more protracted. The complication of this period was, as usual, anasarca; general anasarca and abdominal dropsy often occurred, but never in a fatal form: one case of fatal thoracic effusion presented itself in the case of a child four years old; the cavity of the chest contained two pounds of clear fluid. No case of acute effusion into the cavity of the skull was obscrved.

The treatment pursued by the author seems very rational, and does not differ in any remarkable manner from that which would be adopted in this country. He justly condemns the antiphlogistic method, when pushed to too great an extent, preferring mild cooling regimen, and a moderate use of blood-letting when absolutely necessary. The experiments which he made with cold affusion do not seem to have given very favourable results, and he prefers rubbing the skin with warm oil. The inflammation of the throat did not appear to be alleviated in the least degree by leeches, and purgatives with emetics had not a much better effect. In a word, the result of the author's observations on the treatment of the second period is, "that medicine is only of negative value, and that when a cine does take place, we are indebted to assure for the fortunate result.

Frome, Somerset, Feb. 12, 1836.

THE LANCET.

London, Saturday, February 27, 1836.

THE public mind has once more received a terrific shock in consequence of the fatal catastrophe which has just followed another infliction by the cat-o'-nine-tails, on the back of a marine in the barrack of Woolwich.

But was the flogging the cause of death? The medical witnesses who were examined at the inquest think that it was not. Eight of the jurymen were, in the first instance, of a contrary opinion, but a majority of that body ultimately decided, that "the unfor-"tunate man died by the visitation of God, " and not by the hands of any person or " persons whatsoever." This is the verdict. But whom will it satisfy? None but the advocates of human torture. None but the admirers of a brutal system of treating the soldiers and sailors of this country.

Some of the facts of this case we can state from personal observation. When it was stated in the Weekly Dispatch of Sunday the 21st instant, that another unfortunate criminal had been flogged at Woolwich under very distressing circumstances, and when we further saw, on Monday last, that the victim of cruelty had ceased to exist, and that an inquest was to be held on the body on that day, the Editor of this journal conaidered that as a member of the medical profession, and as the occupier of a seat in the Legislature, it was his duty to see the body of the deceased, and to inquire per- be incidented, and the inquest and affours sonally into the circumstances of the case. Accordingly he proceeded to Woolwich,

a bis arrival at two o'clock. he was mished to hear that the inary had been sitting f and a fall, bed tellimen g morning, to be again reman at nine o'clock. On repairing from the Ship Tavers, where the coroner and love had met, to the Infirmary of the barracks. we were at once admitted to a view of the body. No attempt was made at concealment, no desire was manifested to misrepresent the details, - none to withhold the knowledge of a single fact from any inquirer. The conduct of Mr. PARKIN, the chiefsurgeon of the barracks, was not characterized by the slightest reserve, and his conduct clearly manifested that he had in all respects discharged his duty to the sufferer. The advocates of the flogging system cannot, in this instance, cover the disgrace of the fatal event by accusing the surgeon of neglect, or the absence of a knowledge of his profession, or of unkindness of heart; and both the relatives of the unfortunate soldier and the public may be assured. that all was done in the Infirmary of the harracks, that could be accomplished by medical skill and humane attention, to divert the catastrophe which followed the flogging.

As the young man had died only on the previous morning, the body was perfectly fresh, and no sign of disease appeared upon it, from head to foot, except in the remains of the cruel blood-red wounds (which were situated immediately over the spinous proceases of the dorsal vertebrae), and in the inflamed surface by which those wounds were surrounded. So far, therefore, asternal appearances were concurred in a ing the body, the only se was observed whent ture had been a determined, therefore, by the jary, that examination of the internal organs sho s short time before we reach for the purpose of having

It was agreed, we understood, this memination was to be conducted by the parrack surgeons, by Mr. Bpggan (1) in surgeoul, and Mr. Ga Roll-Bireel Belgel of Ann santely, we'vere prevented free re the more surprised at this circumstance, rithin a very short distance from the baracks. We ask, then, was Mr. GRAINGER nd if so, why he was not questioned in reference to the comparatively inexperinced and unknown Mr. SAMUEL SOLLY? and who were the medical witnesses on arracks; Mr. James Lawrence, a naval urgeon, who was sent down by the head of he Navy Board ; Mr. BUTLER, the parishurgeon, of whom we have heard it said hat he is not unfavourable to the punishtent of flogging; and Mr. SAMUEL SOLLY. young person employed in the dissectingoom of St. Thomas's Hospital, whose eputation as a pathologist has yet to be reated.

After the medical testimony had been were of original that the death was roduced by the flogging, but the other set the verdic there above writ-IN was recorded.

we shall not freest any partion of it on the present ecossion; but shall west the can procure an afficial copy of the tiony, through the instrumentality of a insten in the House of Commons, and an tunder from the Crown. As the report, ar the adjourned inquest, but a brief re- however, in the Times agrees throughout in sert of the proceedings was published to stating that the medical witnesses all conhe Times of Wednesday. As no contra- curred in declaring positively, that the liction of any portion of that report has flogging was not the cause of death, but ince appeared in the journal in question, that the man died from the effects of a ve may, we suppose, take it for granted fever, and that the fever was the product of hat the abridgment of the testimony has some foulness of the air, or of the earth, or een correctly given. On looking at the of the waters under the earth, we cannot st of medical witnesses, however, we find refrain from saying a few words on this part o mention made of Mr. GRAINGER. We of the subject. We must tell these gentlemen, therefore, at once, that their opinions ecause, on returning from Woolwich, we met | are unsound and unphilosophical, and ut-Ir. Grainger travelling in the direction of terly at variance with those of every eshat place, and his private residence is situated | teemed writer on morbid anatomy, and if such evidence-if such nonsense can be termed evidence-were generally received in resent at the post-mortem examination, our courts of judicature, the science of medicine, and even medical practitioners themselves, would be converted into objects of scorn, derision, and disgrace.

Observe. The only apparent cause of the he occasion? Mr. PARKIN, surgeon of the fatal calamity,-the only cause which was subjected to the operation of the senses,-is discarded by these acute practitioners and witnesses, in order that, like so many ghosts, they may spirit themselves into the air, carth, and water, to discover, in absurd conjectures and wanton hypotheses, a reality which they have not the sagacity to detect in a plain matter of fact. What was the state of the health of the man when he was flogged? It was sound and excellent. Nay, it was alleged by all who knew him, that he wen, sight of the jurymen declared that was in rude and robust health. He was in this state on the 8th of February, the day on which his back was lacerated. On the going a verdict 20th he was a corpse. Now mark. The dence, and at medical witnesses are not content with merely saying that they cannot discover the cause of death on inspecting the body, but As the medical witnesses may allege that they take upon themselves to say that the Ann not been correctly re- florging was nor the cause of ceath! Absurdity can go no farther. If in such a respect them that their investigation was case they be incapable of maintaining the Forge than useless. It was only calculated affirmative proposition, how can they prove in standa. Do these gentlemen believe that the negative? We will not say that such the shine covering the spinal marrow may conduct is dishonest, but we cannot refrain be city in from alleging that it is most mischievous. Ah, had there been a medical Coroner in this case, we will undertake to say that the public mind would not have been shocked by such a verdict as has been recorded by the non-medical Coroner for Sarrey.

On the 8th of February, then, the day of the flogging, WILLIAM SAUNDRY WAS in a sound state of body, and when we saw the corpse, on the 20th instant, the day after his death, the blush of health was still apparent on his cheeks, and, as we before stated, there was no emaciation, no sign of disease or injury, except upon the back where the horrid punishment had been inflicted. The cat, as is well known, consists of nine strings of cord, with knots in each string, and a hundred strokes from this infernal machine, would necessarily produce nine hundred cuts on the skin. And on what part of the body was this dreadful nunishment inflicted? Why within a few inches of the brain, the great centre of the nervous system, and directly over the spinal marrow, whence so many nerves essential to the existence of life originate. Good God! The shock which the whole system must receive from the infliction of such torture would be enough to kill the hardiest, the least sensible, of the brute creation. Now. did the medical witnesses cut down through the skin at that part? Did they cut through the bodies of the vertebræ and examine the spinal chord and the membranes immediately under the wounds in the back? If they did make such an examination, how is it that the report in the Times makes no mention of it? And if they did not, how can they dare to allege, in the face of the sholition of the brain system of flogging, profession and the public, that the flogging as it is practised in the British army and was nor the cause of death? If they did navy not examine the state of the spinal mastow.

be cit, personed, and lacerated, with perfect, imputed a Do they think that there is an sympathy between the skin and the nervous system under such torture? Impossible! Their own every-day treatment of affections of the spinal marrow proves directly the reverse. They cup, blister, leech, and canterize the skin immediately where the scourge was applied in the instance before us, to relieve inflammation and other affections of the spinal marrow, and the membranes of that important structure. The bite of a leech, or a bit of blistering fly, can operate on the spinal marrow, but nine hundred cuts and jags in the same situation cannot produce trembling in a single fibre of the nervous system! Oh this monstrous mockery of the unerring principles of the science of medicine! Will these medical practitioners deny that the prick of a pin in the finger, that a fibre of wood in the same part, will often so affect the nervous system as to produce locked-jaw and death? But there is a case, of recent occurrence, quite to the point. What was the cause of death in the case of the unfortunate Miss CASHIN? The application of a stimulant lotion to the skin in the very situation in which this poor soldier was flogged. There was no wound in the back of that young lady. Yet she was literally stung to death by the caustic lotion, and the stings which the soldier received were scarcely less poisonous or severe.

When we are placed in possession of an official copy of the evidence taken at the inquest on the body of William Saunder, shall return to this painful subject but in the meantime, we nation will call,

DETECTION OF ARSENIC.

CONTRARY to the expectation Ministers themselves, the charter for & if the Metropolitan University completed by the 24th inst. ments, halleyer, are sufficiently almit of the choice of a CHAMORISON, and Lord BURLINGTON, who was a senior wrangler at one of the English Universities, and is distinguished for his literary and scientific attainments, will be the first individual appointed to fill that high and distinguished office.

SINGULAR CASE OF DOUBLE VISION. At the London Medical Society on the 22nd inst., Mr. Figur related a remarkable case of double vision, which in some particulars differs from the usual symptoms of such affections. The patient is a young man. aged 22, of abstemious habits, and so studious in playing and writing music, as frequently to lose a great portion of his night's rest. He first began to see objects double about two years ago, but he did not pay any attention to the circumstance. Since then the affection has continued to increase, and he now sees two distinct objects, one a few inches above the other; that which he takes to be the real object, appearing rather the brighter of the two. It is only at a certain distance that he experiences this phenomenon. When near, objects are not doubled. There are no symptoms of disease of the brain. The eye is dark, and the pupil does not contract to the usual extent of healthy What is most remarkable in the case is, the fact of both eyes being similarly affected; so that if the patient closes either, the same result follows as when they are both open. Various opinions were expressed in the Society with regard to the cause. Mr. KINGDON thought that the habit which the eye had acquired of looking at two bars of music at once, together with the absteconsiderable infinence in the production of the disease. Mr. Piccure considered it either to be diseased of incipient amaurosis, that the case of the ball of the free that the case of the that the case of the that the that of the that the case of the case humours. It was the general opinion of the Society, that the great application to music lately addressed by the Inspector of Austomy should be at once dispensed with by the in Dublin, to the Right Hon. Lord Monrats, patient.

After an operation at the Westminster exhibited to the students a new process designed for detecting arsenic in "the smallest possible quantity." The fluid supposed to contain the poison is put into a phial containing a small quantity of metallic zinc. Some diluted sulphuric acid is added, and hydrogen, with the arsenic, should any be present, is evolved. A small glass tube, in-serted into the cork of the phial, gives exit to the gas which is ignited, and a glass receiver is held over the flame. The hydrogen mixes with the oxygen of the atmosphere, and forms water, while the arsenic is deposited in its metallic state on the sides of the receiving vessel.

[Might not this test in many instancesh a fallacious, from the fact of zinc frequently

containing arsenic?-Rer. L.]

ANTIDOTE FOR THE POISON OF MORIson's Pills .- At the close of an eloquent and excellent expostulation on the folly of yielding credence to the falsehoods promulgated by the dealers in quack medicines. for which, however, we are unable to find room, a correspondent adds the following statement:-" I wish to make known generally, for the use of those who are guilty of the folly of habitually taking the Morison's pills, that the best means to be adopted to relieve the distressing vomiting and purging which frequently follow their employment, consist simply in taking copious draughts of lukewarm water (in the case of sickness) to assist the stomach in its attempts to dislodge the poison, and mucilaginous and gelatinous drinks, such as barleywater, linsced-tea, mutton and chicken-broth, will mitigate the severity of the purging, and afford some protection to the internal coat of the intestines from the acrid and irritating effects of the gamboge, aloes, and colocynth, which are found in the pills. Our correspondent most justly remarks that until the practices of quack doctors and the use of patent medicines are interdicted by Parliament, medical science can only be a by-word with the public, as astronomy for-merly was disgraced by the connection of astrological conjuration with its observations and study.

ANATOMY IN IRELAND.

Secretary for Ireland :-

Office of the Inspector of Ameterny, Dublin, Feb. 1st, 1836.

My Lond,—As Impector of Anapony I have the honour to sate the wound had report for the quarter ending the large During the last three months the number of subjects sent to the schools, succeeds that and during the spairs of the year beliefs last.

An attempt was lately and to revive the revolting practice of exhausting two of the party were sent to New and thought it prudent to permit them to join the Queen of Spain's troops, with their ringleader Malone (whom I had formestly convicted). Thus has this gang of desperadoes been transported with their own consent.

I am happy to sequaint your Lordship that the advantages presented to the Students of Anatomy in Dublin, are now equal to those of any other part of the world. The supply of subjects is regular without conflict, and abundant without outrage to public feeling, as formerly. The gratifying testimony to that effect of the Professors of the eight schools of Dublin was published in The Lakert of March 14, 1835.

The approbation expressed by the Dublin Professors has been further confirmed by the annexed testimonial from a very influential public body. The Inspector has only endeavoured to carry into effect the enlightened intentions of our liberal Government. I have the honour to be, my Lord, your obedient servant,

our obedient servant,

JAMES MUBRAY, M.D.,

Physician to the Lord Lieut, of Ireland.

ROYAL BELFAST ACADEMICAL INSTITU-TION; Joint Boards of Managers and Visitors, Feb, 2, 1836; Extract from the Minutes.

Resolved Unanimously,—"That the thanks of the Joint Boards are due to Sir James Murray, Inspector of the Schools of Annatomy, for his uniform attention to the interests of the Anatomical class of this Institution.

JOSEPH STEVINSON, Secretary."

Medical Compress in Irrland.—To the Editor.—Sir.—In compliance with a desire expressed in a late number of The Lander, I herewith send you a list of the Irish medical corners, with their places of residence, taken from Pettigrew and Oulton's "Dublin Directory" for this year. I am, Sit, your obediends servant,

Joun Browns, M.D. 25, Helles-st., Merrion-sq., Dublin; 30th Feb. 1836.

Manufactor, Robert Murray, M., Beech.

Watters, James Hamilton, M.D. (and two others), Gorey.

MR. MORGAN OF GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,-I shall feel obliged, as will the rest of Mr. Morgan's bearers, by your giving insertion to the following statement, though it is with extreme reluctance that I make any complaint on the subject. I do, how-ever, most justly find fault. The apathy, disrespect, and apparent indolence, of Mr. Morgan towards his pupils, compel me to adopt this mode of troubling you for a small space in your valuable publication. Mr. Morgan announced at the beginning of the session that his lectures on ophthalmic surgery would be delivered on every Thursday evening, but after the first three lectures Mr. M. seldom has appeared for any two weeks consecutively. Consequently, he lately had to announce that, unless he lectured three evenings a week, it would be totally impossible for him to complete the course ere the middle of June, but if the pupils would listen to three lectures per week he could terminate the course by the end of March, and, as he did not feel particularly anxious to lecture to empty benches, he hoped that some gentleman present would take the sense of the meeting and communicate it to him in the museum, where he would await the proceeding, which ended by a great show of hands in favour of three lectures being given a week. Yet Mr. Morgan bas not given a lecture on a Thursday evening since, which will be three weeks up to Thursday, February the 4th. Mr. M. cannot have had the interest of his pupils in view by this neglect; he evidently has thought that he might neglect them at his pleasure. I shall forbear saying more at this time, awaiting some suclosis is M. at his next lecture, or ance of the three as are must be well aware th to arrange their thunds and most likely and most in ordered new arrabi

Contraction of the second

COLLEGE OF PHYSICIA

Ga Monday evening oduced at a visitor at the the season, of the College of Parele as I am but little accustomed to such proceedings—at all events have not been made insensible to their impropricties by habit and being, moreover, personally uninterested, and, therefore, it may be presumed, as impartial observer, you will perhaps favour me with an opportunity of stating what impression was made upon me by the scene. In doing this, if any one should think me an uncourteous guest, I would simply say, that I make no scruple in sacrificing courtesy to justice and professional usefulness, when both happen to be incompatible. There were present, as I am told is generally the case at their first meeting, a number of distinguished individuals, -the two archbishops, several bishops, the premier, and some other leading political characters. Two things, above all others, awakened my reflection, viz:-the conduct of the President as an individual, and that of the College as a body. The president delivered an oration on the death of some individuals who were distinguished for their attainments in science, Bacon, Boyle, Newton, Locke, Addison, Johnson, and Sir W. Jones. It contained a brief account of the circumstances attending the death of those eminent men, and a more particular description of their moral and religious characters. They were held up as examples to stimulate our virtue. and to strengthen our confidence in the faith we have adopted. Prom this account the discourse would appear to be sufficiently appropriate, - for I think on such an occasion it should not be wholly unprofessional, nor on the other hand so technical as to be uninteresting to the non-medical guests. But the mode of its execution removed from my mind every favourable impression made by the plan, and substituted in its place a feeling, deep and unmingled, of disgust and abhorrence. My object, Sir, is simply to express my feeling, not to prove It to be het, for that could not be done to one who did not witness the exhibition, and the those who did I am sure it need not. This discourse then convinced president did not care the same the same to was determined to the mine the same to the same the same to the same

the same

most discreligious character of this age and again, what any man should dare to deliver such; a discourse in the presence of the legiting man of characters, and of a liberal if learned profession. Yet all this is done by the homital, head of the medical profession is England, the obief official medical attendant of the monarch. Can it be true also that he has acquired this station more by this and interest practices than by the execution of the monarch of the profession?

the second matter which arrested my attention was the separation of the fellows from the licentiates. The upper part of the room was barred off, for the exclusive use of the president, the fellows, and the titled guests. Over the other parts wandered the licentiates and the minor attendants! To argue that the fellows were thus set apart for their merit, is to outrage truth most grossly. If a man has been at Oxford or Cambridge, though he may have spent his time in every species of hypocrisy, blackguardism, and debauchery, he may become a fellow of the College. It is useless to allude to individuals, the principle being the important thing ; but on this occasion I saw, amongst many other men equally worthy of being mentioned, the vice president of the most learned society in Europe, thrust as a licentiate among the lower ranks, like a boy in a booth, to stare at the show prepared for view in another part of the room. How can such an impudent and degrading system be tolerated even for a single moment. Finally, Sir, I am astonished that the licentiates will go to the College at all. They should stay away in a body, and thus diminish the number of gazers. I am, Sir, your very obedient servant,

OBSERVATOR. London, Feb. 23, 1836.

Dr. W. CUMMIN.-Mr. Editor, -However contemptible your opinion may be of those individuals who contribute to a journal whose main object ever has been to traduce the character of the general practitioner, and to libel the students, it is monstrous to suppose that Dr. Cummin should come forward and publicly dony that he was not the coadjutor of Dr. Rod. Macleod. Permit me to ask if it be not a fact that the papers read before the Medical and Chirurgical Society are instantly sent to Dr. Cummin for the sole and avowed purpose of enabling the said Dr. C. to make such extracts and abstracts from them as he may, in his wis-dom, think fit for insertion in the Gazette. Should you have any doubt of the truth of this statement, let me refer to Mesers. Clearespect real religion. I was simblet choked dinning and Partridge, the present Secrewith dispute at this apparent mockery of a terries of the Society, or their predecessor, sacred things, I think is an indelible stain who tas kinself become so expert in mak-

1. 自由海峡中部建筑工具

ing "Elegan Extracts," and by whom these errangements with the Gazetta were or ginated. I am, Sir, your obedient servant, A FELLOW OF THE SOCIETY

Feb. 22, 1836.

Dr. W. Cummin .- To the Editor .- Sir, Something more ought to be made known with regard to the expostulatory letter addressed by Dr. Cummin to you respecting the secret editors of the Medical Journal Notwithstanding the statements therein made and conjointly testified, I understand that the gentleman who questioned Dr. Cummin, positively declares that Dr. Cummin did deny to him in explicit terms that he had any thing to do with the editing of the Gazette. Dr. Cummin it is thought was alarmed into telling this story by the momentary fear of avowing the connection, but having gathered courage afterwards when he saw the statement in print, he denied that he had ever disavowed the connection, because his acquaintances would have thought worse of him as denying what was so notoriously true, than they even did for his hiring his time and services to Dr. Macleod. This is the report. The student, I understand, was warned not to question Dr. Cummin without having by him an independent witness, but he was too unsus-pecting to take the advice. However, he came straight out of the room and told to every one around exactly what appeared in the letter in your journal. I am, Sir, yours obediently,

St. Bartholomew's, Feb. 19, 1836.

QUACK PILL ADVERTISING.

To the Editor of THE LANCET.

SIR,-You mention that you shall speak further respecting the late murder by Morison's pills. I was induced the other evening to visit Exeter Hall for the purpose of hearing a Dr. Lynch lecture on hygeine. Morison himself, I believe, was on the platform. Between two and three hundred supporters of the system were present, and applauded to the echo the attacks of this "Doctor" on the profession. His subject was apoplexy, and he misquoted a number of great authorities to prove that they decided on condemning bleeding under any circumstances in that affection. His lecture was has been tarnished a tissue of absurdities and abuse. He spoke a few intersects persons of the late murder, and said the victim was fears of their fellow statem. of the late murder, and said the victim was doing well until the " Doctors" were called in. He afterwards left the Hall in a carriage, which had, evidently for effect, been placed at the door for a long time before

corenet upon it, and livery servants se outer coats showed much than other portions of their dress. dient de

LATE ADDRESS TO APOTHEC HALL.

To the Editor of THE LANCET.

Sin.-From the zealous and able manner in which you have uniformly advocated the rights of students, I feel it a duty to apprize you of any circumstances connected with the subject.

I see on the cover of the last week's LANCET, a number of names of students at the London University, who affirm that they were opposed to, and had nothing to do with, the meeting at the Crown-and-Anchor; at the head of the list is a Mr. LEGGATT, who is a pupit of that very courteous functionary, Mr. Secretary Watson. Doubtless this Mr. LEGGATT will be recompensed for the pains he took, during three or four weeks, in endeavouring to collect a tolerable list of names for the support of his master's interests. I need hardly say, Mr. Editor, that the greater part of these honourable and liberal minded students, in a short time, intend to present themselves for examination at the Hall in Blackfriars; and I have no doubt that this mean-spirited publication of their names, is designed to act as a demulcent on the surly growl of a WHEELER, or a Ridour, or to restrain the annoying gesticulations of a Meranman. I am informed, on the authority of a student who was present at the first meeting at Anderton's Hotel, that not a few of these celebrated gentlemen took a prominent part at that meeting, and even wished to become proposed as members of a committee for conducting the succeeding meeting at the Crown-and-Anchor. A Mr. BRIGHTMAN was very conspicuous on the occasion. So much for the firmness of the students at the London University. I consider this proceeding a most unjust one towards all those gentlemen whose names have not appeared in the list (many of whom have taken neither side of the question), inassurch as of course they will be considered at Apothecourse they will be consid carics' Hall as having approved of, or tak a part in, the meeting. I am ask such conduct in medical that the character contains Sir, your obedient servant, A STOURT OF MEDICINE AT THE

LONDON UNIVERSET. 1350 February 13, 1836.

To the Miller of The Mill SOFT.

Size is entrout you to extend your kind-east the who carnesdy desires to insise notificate that there are supposed tores of medical students to the fonders University, who have not suggraced their names by signing the cringing indirect petition to the Apothecaries' Company, allowed by you to be advertised last week. The professed object of the advertisement is perhaps without parallel in the way of excess for its appearance. The petition is said to be got up to negative a pretended report, that the students of the University organized the late meeting at the Crown-and-Anchor. But it is really designed to furnish the Apothe-:aries' Company with a list for reference in case its favour should be necessary during some future examinations. How disgraceful thus to follow the example of the agents of the Apothecaries' Company at King's College! And, worst of all, to attempt to betray those fellow students who, from motives of conscience, refused to place their names among those of the frightened memorialists. When I entered my name as a student in medicine at the London University, I did so partly in consequence of the liberal principles on which the school is founded, thinking to enjoy the society of students whose minds and actions were far above those whom I had lately quitted. I sought the companionship of independent men, men with higher characters and objects than might be cherished elsewhere. How miserably am I lisappointed on finding, in a moment, that I am among so many who profess liberal principles only as a matter of convenience! The petitioners, too, have prostrated themselves at an age when the mind is more usually moved by generous and bold impulses. The proceeding might have been excusable in weak old age, whose long experience too often brings timidity, but for men who are beginning life, it is a sad commencement. You, Sir, whose constant kindness to the London University can never be repaid, are willing to ascribe this silly act to the fears of youth, but there is an armour which students may put on that is proof against intimidation, and he who wears t next sing thin, towars.

If the statement of the London University bold epicions which are adverse to the pre-

that medical surplations, whether agreeing in not with the distinct and at the Croum-and-packer, the common than the common to other schools, the common them frankly, and not merely say, "We disclaim, do." what others merely say, "We disclaim, &c." what others have done. How poor and how feeble is

to an announcement! Change of individuals alone can change the public opinion of the students of the London University, so fouled this advertisement. Allow me, Sir, in senclusion to add, that the advertisement has completely marred the expectations of those who watched with pleasure the increase of our liberal school. The ignominious stain time alone can remove. Your obcdient scrvant.

A STUDENT IN MEDICINE AT THE LONDON UNIVERSITY. London, Feb. 22, 1836.

LATE ADDRESS TO APOTHECARIES' HALL

To the Editor of THE LANCET.

SIR,-The document published on the wrapper of the last LANCET, is remarkable from more causes than one. The first name that appears in the list is that of Mr. LEG-GATT, the late apprentice to Mr. WATSON, the secretary of the Society of Apothecaries. The fourth name, that of Mr. Aynes, is that of one who is already known to the Court of Examiners as being connected with a botanical prize, and who thus expresses his gratitude for the gift. The name of Mr. A. Tibson, a little lower down, is that of a student who received a similar honour. He, too, thus repays his gift. Several other names are those of apprentices of Examiners at the Hall, or of persons who are particularly interested in the welfare of the Company, and these gentlemen have been the indefatigable agents and promoters of the address. They have left no stone unturned to get names to prove - that it is time that the examinations for diplomas were made public! I am, Sir, your obedient servant,

AN UNIVERSITY STUDENT. Feb. 23, 1836.

To the Editor .- Sir, - Permit me through the medium of your valuable journal to respectfully recall to the recollection of Dr. Quain, an assertion contained in his prospectus, issued precedent to the publication of the first division of the series of "Anatomical Plates illustrative of the Structure of the Human Body;" viz. "The work is in such a state of forwardness, as to ensure a regular publication; a fasciculus will be ready for delivery every fortnight on the 1st and 15th of the month." Need I add that the promise has not been fulfilled? It is not the opinion of one individual, but the united the fecturation, and the more so from the opinion of many, that the future fate of the great taught of time which has clapsed, be work mainly depends on a speedier publicator that father sentiments could be forced tion, for this reason,—that numerous peropinion of many, that the future fate of the

some have relinquished the work, fearing th that the several divisions will never be con pleted, and that dependent on the per-alow publication, by hastening which Quain would confer a great obligation. pleted, and trac supplication, by haster only on the numerous class of medical dents, but on medical men generally. Sir, your obedient servant,

A MEDICAL STUDENT. London, February 23, 1836. 1778

WESTMINSTER MEDICAL SOCIETY.

Saturday, Feb. 13, 1836.

Dr. Apprson in the Chair.

THE amount of the Society's funds was announced this evening, and it appeared that they were at a low ebb compared with the funds in hand in the preceding year, the difference arising from the small number of new members this session.

Dr. Johnson detailed some further particulars of the case of affection of deglutition and articulation reported in a late Number. The patient was better to-day; the stomach can receive, without much incon-venience, double the former quantity of broth. When injections of broth were administered, although opium was mingled with them, attempts at vomiting had generally followed, but not when the broth was passed into the stomach. The system still, as before, retained the nutritious portions of food, and when vomiting took place, all but the nourishing parts were ejected. The pulse, however, gets weaker, and her strength decreases. He proposed to pass the electro-galvanic shock from above downwards, in front, along the course of the eighth pair of nerves, which he believed were implicated in the disease.

Mr. STREETER inquired whether apoplexy during pregnancy was likely to affect the child, and whether utero-gestation pro-

ceeded after an attack.

Dr. Uwins supposed that apoplexy was of rare occurrence during pregnancy. He regarded the pregnant condition as desirable to the female who was predisposed to

apoplexy.

Dr. RYAN related a case of pregnancy, accompanied with apoplectic symptoms,-the pregnancy eight months advanced; but the patient was predisposed to cerebral affection, and the attack was induced through taking twenty-five drops of laudanum, which treatment than was led him to regard it not as a genuine case of it was far where to applied the apoplery occurring during pregnancy. A on the more charged the freshment practical point, of considerable interest in a las to Hahnemanium, though it might be

Mr. STREETER said that he also thought were more interesting to the

ne apoplexy during pregnancy as three months a third of her age. ettacks in bringing on wis miscarriages and by . Notwithstanding the present ack of apoplexy, gestation was propeed-The paralysis of the left leg, which we are the paralysis of the same side remains persanently affected. Consciousnoss existed up to the time of the attack. The approach of the fit was manifest to a child, by an alteration in the voice, and a particular appearance of the eyes. The sufferer said she felt cold and faint, and experienced a deadened state of the left side. She returned home from a short distance, and ascended a few stairs, but shortly after was found by the servant in a state of insonsibility, in which she had remained from ten to fifteen minutes. When somewhat rallied she was bled, and leeches were applied, as she complained of pain over the temples. What was the proper treatment in such a case. Should delivery be encouraged?

The members preferred discussing Hahnemanism, and the question of Mr. Streeter

remained unanswered.

Dr. Johnson here made some remarks on Hahnemanism, which we reported last week.

Dr. Uwins acknowledged his total ignorance of Hahnemanism, but as some men of acquirements and good character had embraced the doctrine, he thought it ought to be examined before condemnation. No doubt, Dr. Johnson recollected when he (Dr. J.) condemned phrenology, which he now advocated.

Dr. Jounson replied that he did not ad-

vocate phrenology until he had studied it. A discussion ensued between Mr. STREET-ER, Mr. King, and Dr. Johnson, with regard to the administration of large doses of tartar eructic, which the two former gentlemen characterized as very dangerous, much mischief being ascribed to the extent to which it was often prescribed. Indeed, remedies in general (Mr. King thought) were given in much too large dages, and especially those of which was possificable pronounce the causar effects at mode of operation. Mr. King. cffects a timole of operand that in said the se was fully estimated that in said the way man and trained trained medico-legal sense, was that the delivery rafe sometimes, it was not adapted to the was accomplished during the state of basis treatment of discuss of a grave mater.

PRESENT TO MR. SERVICES

On Wednesday last the trades above school assembled in the purpose of Jacks. The purpose of the

Mr. Chaldecor having been unanimously voted into the chair, briefly and appropriately stated the object of the meeting. Two very highly-finished silver salvers were then brought into the theatre, and exhibited as the intended gifts. Upon the larger was engraved the heraldic arms of Mr. Grainger, with the following inscription:—

"RICHARDO D. GRAINGER,

Viro Humanissimo, praceptori anatomia peritissimo, hoc argentum in diuturnum, tum virtutis, tum ingenii, testimonium dono deterunt alumni

A.D. MDCCCXXXVI."

Upon the other was engraved, "Presented in the Theatre of the Webb-street School of Anatomy and Medicine, to Richard Dugard Grainger, Esq., by his pupils, as a very sincere expression of personal attachment and respect, and in especial testimony of the very high sense they entertain of his zeal and ability as a teacher. Feb. 24, 1836."

The Committee then waited upon Mr. Grainger to request his presence, which was accordingly acceded, amid the loudest shouts of applause. When the cheering had subsided, Mr. Grainger was addressed by

Mr. BICKERSTETH® as follows:—"Sir, often as you have been welcomed into this theatre, the occasion was never, perhaps, attended with such a thrill of delight on the part of the welcomers. I approach you on behalf of the purplis, to present you with a minorial of their esteem and regard; but honomials as is the wine. I have to perform, it is one which is attended to the portion of the gratificating of knowing you always as its any was attended to the property of the property

sing of our attachment and respect. I so not refrain from saying much on this occa-sion because I do not feel much, or because the move the hearts of those who have puted me to represent their sentiments. com presence prevents me from adverting Thany things which I should be anxious to my in evidence of my regard for so excellent a teacher, while amuring you of their esteem and respect. Recollecting the circumstances which this school was formed, and emembering the unparalleled difficulties it has had to encounter, we are persuaded that the undaunted resolution, indefatigable perseverance, and resplendent talents, exercised by your late lamented brother and yourself, could alone have raised it to the eminence which it enjoys, after having crushed the thraldom of monopoly and oppression. (Loud Cheers.) Long may it flourish, sir, under your skill and protection, and ever retain its character for industry and independence. It is not my intention, on the present occasion to enter upon a lengthened review of the peculiar difficulties that at one time impeded the onward progress of our profession. but I may perhaps be permitted to remark we are aware of them. - that we are sensible of the extraordinary impediments which were opposed to the exertions of the late respected Edward Grainger, before he succeeded in gathering round him a larger body of pupils than ever flocked to the prelections of any anatomical teacher in this metropolis. But not only did he found a school, which soon became marked for the acquirements of its scholars, but to him may be ascribed the credit of having raised the standard of medical education to a height which it had never before attained in this country. (Cheers.) Individually, as a scholar, I feel a debt of gratitude to-wards him. As a member of the medical profession, I feel it infinitely increased. Would that he could be present! But there is among us one who has confirmed that success which it was to be hoped would crown his labours, -- one of his earliest associates in the school,-one who now upholds its reputation with remarkable energy. (Loud cheers.) To him, on bohalf of the pupils of this school, I beg to express the fervency with which the impression is entertained, and to him,-to yourself, Sir,our warmest thanks are due. Your unremitting efforts for the welfare and advancement of your pupils demand this from them. The merits of the school do not consist in the magnificence and stateliness of its walls. (Hear, hear, hear.) To its internal arrangements are the honours which attend superiority due; and, in this respect, the school of Webb Street may proudly lift np its head as high as that of any school in the metropolis, and no title among students

This mentionen is, we believe, the sephent of the lately appointed Master of the

can rank higher than that of behits under founding of this school (and in the benefits of the instruction of a Grainger, a pupil of this school. (Loud cheers.) With the earnest where the school in the property of the success of your exertions in the growing advancement of the institution, lidly according the field of gratitities which and that it may be an important place of Languello where the success of your exercions in the growing advancement of the institution, lidly according the field of gratitities which and instruction in the new Metropolitan University, I now, on behalf of your admiring university, I now, on behalf of your admiring university, I now, on behalf of your admiring university of the school. I can hardly describe the difficulties which her

dress a public assembly, and still less an assembly in this theatre, where, at all times, I have been received with the strongest proofs of attachment from my pupils, yet, the present occasion, I assure you, finds me at a-loss to express to you the feelings of grati-fication under which I labour. But I will not, with the vanity which is so inseparable from our nature, attribute all the kindness you have this day manifested, to mere personal motive, but to higher and more distinguished objects. In this institution I have aided in the establishment of a system the reward which usually attends indefatigable industry, and to the influence which this school has consequently had in promoting the general welfare of the medical students in this metropolis, and the improvement of medical education generally, do I chiefly ascribe the possession of those bonours which have been conferred upon me to-day. This theme is to me more grateful than that of my own humble talents. Few who are now here can tell the condition of the metropolitan schools, or the condition of medical education, when this school was first established. At present it must afford us the greatest satisfaction to see that, in every school in this metropolis, the only rivalry among the teachers is who shall most efficaciously discharge their duties, but there was a day in which the medical student had to look rather to his own unaided and unguided exertions than to any benefit he could hope to receive from his instructors. (Hear, There was not then, in this great hear.) metropolis, probably more than one teacher to four hundred students, and you who are employed in the active study of your profession must be aware how utterly incapable one individual would be to afford instruction to so multitudinous an assemblage. The stuto so multitudinous an assemblage. The stu-

pupils, solicit your acceptance of these me- hardly describe the difficulties which he morials of our esteem, attachment, and re-bad to meet offered to his progress by opspect. (Great cheering.)

Mr. Graingra, amid a repetition of the in the professions and his competitors were cheering, then addressed the class.—Al no less in abuse than a Cooper and an though, gentlemen, he said, I cannot plead the excuse that I am maccustomed to adthe school, but he sequired for it in five years the highest reputation, and he had assembled around him, unaided by the slightest extrinsic agency, a larger class than had ever before attended the most celebrated teacher of this or any other metropolis. I lately had occasion to send to his Majesty's Government an account of the number of students who attended his lectures, and I confess to you, that although I was aware that their numbers were very great, yet, so many years hav-ing elapsed, upon referring to the book in which these, in some degree, sad memoin which the teachers, trusting solely to rials, were recorded, I was surprised to see their own merits for success, have met with i the immense number to which they reached. Gentlemen, my only claim upon your kind feelings arises from the circumstance that I have, in some degree, with the assistance of my able colleagues of that and subsequent periods, maintained the success and reputation of the school. (Hear, hear.) I mentioned to you, gentlemen, that when this school was first instituted, the profession of teacher was in a very few hands, and the system allowed them all to be appointed through the means rather of family connection and influence with powerful corporations, than any intrinsic merit of their own. Not that I wish in the least degree to reflect upon individuals. I speak of the system, and say, without the fear of contradiction, that the plan at one time was to adopt only those teachers who had the strongest recommendations from relations, and who could catch the car of those who had the bestowal of the bonours of the profession in their hands. (Hear, hear, hear.) Observe the contrast now. It is not from the name of an institution; it is not on the score of its employed in communicating a knowledge of wealth that success is to be found. The practical anatomy to a class of from three present age looks more to best than to proto so multitudinous an assemblage. The stu-dents were entirely thrown upon their own schools of this metrogolis, whether they resources to obtain that acquaintance with have not originated from the talents, the the human body which is so indispensable services, and the unabated exertions, that to the safe practice of their profession. You were simplyed in the founding of this actually will judge, then, what medicine owes to the Not that my brother was the creating shows.

principles which are now in operation. He was merely their representative. With regard to myself, gentlemen, at the fine when I was called upon to fill the effice which I now hold. I was in stary respects unfitted for its duties. I was necessary the start of the control of the contr for the dagles. I was unprepared by previous education but I studied unabaticable to passed use to contend against that the state on which my brother experienced is M. its virulence. I make no personal reflecof public bodies, we are justified in employing the utmost scruting the state of the constant in the const thing like personal reflection on the conduct of my competitors, but I will boldly assert that some of the corporate bodies of our profession left no efforts unturned to suppress this school, and, gentlemen, the attempt was to suppress freedom of instruction, and the independence of the medical student. Yet you, who are the junior members of our profession, have as great a right to choose who shall be your instructors as the first persons in the land. (Great cheering.) The attempt, however, was made to suppress every private medical institution in this metropolis, and so to limit the choice of the student as to where he should receive his of Surgeous of this metropolis issued a series of regulations, in which they stated that they would not receive certificates of attendance upon lectures delivered in any private school, unless that school could obtain the recognition of one of the metropolitan hospitals, thus throwing the guardianship and the rights of our profession into the hands of the hospital surgeon and physicians of this metropolis. Ought the Colpower of crushing private institutions on rival bodies in the public schools? Governing bodies should retain to themselves those discriminating powers which, when justly and honourably applied, no one could complain of. I will just state how far these regulations were aimed at myself. College of Surgeons not only would not conege in Surgeons not only would not recognize any private school, unless it had previously seedled the recognition of one of the hospitals; but they held a discussion, the state of the hospitals; but they held a discussion of the seedled of attendance on which has been received by the College of Surgeons, thus jitted days we means of this Surgeons, thus intending, by means of this ex post facto law, to put me and the school

to an individual to whom I feel deeply indebted in those transactions. I allude to a highly-distinguished surgeon, who enjoys an European reputation, who advocated my cialms when the question came to be considered at the College of Surgeons, and by which means this school was preserved in existence. I allude, gentlemen, to Sir Astley Cooper. (Loud cheers.) There was a great discussion in the Council as to the reception of my vertificates, and Sir Astley Cooper, as I have heard, strongly advocated the justice of my claims, and it was represented to me that had it not been for that advocacy, in all probability my certificates would have been rejected. This is the only allusion, gentlemen, that I shall make to any individual, and I make this public avowal of the high sense I entertain of his liberality on that occasion with the greatest pleasure. energetically made by the College of Surgeons | Fortunately the time has now gone by when against myself. Through me they wished the acts of a self-cleeted Council can suppress those principles of medical education which have since extended with such rapidity and power, not only in London, but in almost every considerable town in the kingdom. This opportunity of gaining medical instruction in the country is most valuable to the student. I conceive it to be a point of immense importance that as soon as the whole routine of compounding, and so forth, is understood, the medical student education. Within six months from the should be initiated into those principles period of my brother's death - aye, within upon which the successful practice of his three months-the Council of the College profession must rest. There is no fear of medical education again retrograding. Gentlemen, for myself, I have been enabled to take but a trifling share in the work, and the difficulties which I have had to overcome have been balanced by many pleasures. I have ever received the warm support of the students of this school in my efforts, and not only in a public point of view, but I am proud to acknowledge that some of the most valuable friendships lege of Surgeons to have bestowed the I have ever formed I owe to my connection with students as a private teacher. I am, too, most ably supported by the talents of my colleagues, and not only by that, but by the strong feeling which has existed in the profession generally, that to support this school was to maintain a great principle. These advantages were quite sufficient aid to my laudable efforts. hear.) Gentlemen, amid so much, which both retrospectively and at present is highly gratifying to me at this moment, there is one circumstance which I confess throws a shade of gloom over this occasion. I am sorry that among my excellent and worthy colleagues I do not observe one here who is as dear to you as he is to myself (Mr. Millard). I have had the opportunity of watching his rising worth, and the happiness of seeing him placed in a situadown. I am perfectly justified in alluding bappiness of scening him placed in a situa-to these acts of a public body (cheers), that tion where his excellence could be esteemed I will the company on a larger scale. And I regret that we are fluence and habits of my mind. I am not accustomed, nor do I wish, to intrude my self on the ground of my own personal value. I would rather look on this costly present as a proof that you admire the system of which I in some measure have been the representative, than as the reward of any exertions of my own. Yet if any labours of mine have in the least degree contributed towards advancing the welfare of the pupils of these schools, if in short I have deserved, as I have this day received, so ample an expression of your approbation, believe me my utmost ambition is gratified.

Mr. Grainger then withdrew amidst loud and long-continued cheering, and votes of thanks were unanimously given to the chairman, and to Mr. Davis, the Hon. Sec., for the able and satisfactory manner in which they had discharged the duties allotted to

them.

Those gentlemen having returned thanks the assembly dispersed, apparently with feelings of great gratification at the proceedings of the day.

COLLEGE OF PHYSICIANS.

THE Soirees at this medical show shop, inside of which we have once a year just such a display as is made to the gaping multitude outside of Richardson's booth at Bartlemy-fair, were resumed on Monday last, and every exertion was made at this eventful moment to produce such a display as would strike the licentiate populace with admiration of the extent of the worldly connections and influence of Sir HENRY HALFORD, and convince them what folly it was to try to reduce the professional power of a man of genius in the strong hold of a Royal College. The populace came, and we believe were fully convinced both of the absurdity and the impropriety of directing the battering-ram of reform against the walls of a citadel which contained within it such an army of archbishops, lords, lawyers, artists, and eminent fellows, as were found in array on the present occasion. The Emperor Nicholas, at Kalisch, had not more cause for, nor found better success in, exhibiting his troops to the view of his intention to come immediately to the Europe, than had Emperor Harrono in ald with an everwhelming force.

deprived by an melanoholy series of his Bell Mill in Monday night. In fact, the presence. Gentlemen, I will not treat my list the and subordinates having attended salf to speak further on this distribution, had the gomfort of acup of subject. Enough, gentlemen, has been all the list departed. Salf resolutions to myself; too much for the ordinary in subjects the single resolutions to myself; too much for the ordinary in subjects the single resolutions to myself; too much for the ordinary in subjects the single resolutions of superhuman college de accustomed, nor do I wish to intrude my light field against the Aughthaus of THER and CANTERBURY. LOS FE. LANSDOWNE, WESTWO and HARROWSY, the PRIMATE, Lord Ser-TON, SIT MARTIN ARCHER SHEE, Mr. GOD-WIN, and other such powerful medical warriors?

Some considerable time, of course, was allowed to the licentiates, and the top-apothecaries and the top-apethecaries' apprentices who were mixed with the army of licentiates, to contemplate the enemy, and that period was occupied by an oration from his little Majesty, who took the field in person, and occupied the centre of the troops. The subject was wisely and discriminately chosen. Death and immortality formed the theme. In times of war the hosts of battle need encouragement to fight to the death, unless immortality is the reward. With extreme delicacy and tact, however, the orator avoided a direct selection of illustrations from the military mausoleums of antiquity, and as the institution to be defended was one of science, he drew his inspiriting examples from the last scenes of the illustrious philosophers of the two past centuries,
—from the deathbeds of Bacon, Boyle,
Locke, Newton, Jones, Addison, Dryden, Johnson, and Pope, who all died "in the purity of the gospel, by whose light," &c. &c. The oration produced its full effect. The orator had taken the pains to learn the oration by heart, for he pronounced it with one eye on the bishops and the other on the ministers of state, wisely watching in their countenances the impressions which his theological topics and his natural eloquence were producing, as the sentences rolled in a beautiful Mosaic stream of mingled English and Latin, from his lips.

Those licentiates who deposited their helmets and coats of mail with the suttlers of the camp, while looking on in the sultry atmosphere, had better luck with them at the retreat this year than in 1835, when such a number were stolen that a great portion of the retiring troops went home almost naked. On this occasion better care was taken, and only a few suits of usper armo were lost.

It is said that the licentiates found enemy so strong, that in a street of held the same night at the meum was resolved to make specialization power for intervention in their that the famous General, Bearne Rica, of the kingdom of Westminster, has signified Tathe Editor of Two LANCES

remarks on the adverti Shal students of the Lond tweeted in your last Numb That you regarded it as an aid of the prayer of the great meeting in the Strand, and as a proof of the iniquitous power and influence possessed by those secret tribu-nals which can, by exciting the terror of some candidates for examination, exhort such a declaration from so great a number of students." But, in another part of the article, you stated that these gentlemen formed no part of the meeting at the Crownand-Anchor. This is a mistake, for a number of the students who have signed that document were present at that meeting, and voted in favour of the resolutions. I have asked some of them, why they signed a paper which stated that they had not had any connection with the meeting, its originators, or its proceedings, when the reply was, "Because I am going to the Hall.

But, Sir, the advertisement is not solely signed by the medical students of the University. In the list there are the names of gentlemen who are merely general students in the University, and also of many exmedical students who are now surgeons and apothecaries, having passed both College and admirers of the present system of examination, and they used every endeayour to obtain signatures to it, not serupling to get gentlemen to sign it, who, as I have before stated, are not medical students. - The originators of the document not wishing to pay the expenses of advertising it themselves, and wisely thinking that if they asked for a subscription at | the time of asking for the signatures, they would get very few of either, they had recourse to the following manguvre :- they said not a word about the subscription until they had got all the signatures; then they placed a paper in the headles room, stating that it was necessary for each gentleman who signed the paper to pay one shilling for advertising it. And by this method they have got a considerable number of shillings. they fatend to do with the surplus I Fremain, Sir, yours in haste, SCRUTATOR.

The which had given rice to gum-hoil. tecnous was on the increase, and being ought expedient to remove it without. delay. It filled the situation of the second temporary grinder, but in its growth had displaced two of the adjacent teeth, occupying about an inch and a half of the alveolar process on the right side, The operation was performed in the following manner:-An incision, commencing a little above the point of the chin, and being carried along the base of the jaw to the angle, in a semilupar direction, the flap was dissocted up, so as to expose the bone, and open the membrane of the mouth freely; the mylo-hyoideus and other parts connecting the tongue with the inner side of the jaw were then detached, the knife being introduced from without, and guided by the finger of the left hand, introduced into the mouth. The full extent of the tumour being then distinctly ascertained, the first temporary grinder, the permanent lateral incisor, and the first permanent molar teeth, were immediately extracted. A small saw was applied in front and behind the tumour. in the spaces from which these teeth had heen extracted, so as to divide the jaw to some extent perpendicularly. A pair of strong cross-cutting pliers were then em-Hall. The originators of the document are ployed, so as to embrace the portion of the bone to which the base of the tumour was attached. This was easily divided, and the The wound was tumour was extracted. then brought together by two or three points of interrupted suture. The whole proceed-ing occupied a very few minutes. Mr. Liston afterwards remarked that it might appear to be a severe operation; the suffering, however, was not so great as would be supposed, but all operations upon the jaws had a frightful appearance. He had made the incisions in such a way, that had the tumour been found to involve the jaw more extensively, the whole thickness of the bone, to any extent, might have been extirpated. It was impossible, before the incisions were made, to know the exact extent of the tumour, and he considered it proper to proceed in such a way, in order that, under any circumstances, the whole disease might be removed. Fortunately it was found possible to preserve the base of the jaw. Consequently there would be little or no deformity. The disease he added, was very rare in young subjects, and he never before, out of a number of cases which he had witnessed or treated, had seen it follow any decay of the temporary teeth, or disease of their sockets. The tunour scened to the man last removed an osteo-saresus touch to be composed partly of soft matter, our tunions, from the lower maxillary bone and partly of bone. It was a "veritable of a little december of the same and partly of bone are removed. sercoma."

REPORMED MUNICIPAL CORPORA AND MEDICAL COBONERS.

Mr. Greece Rossason, Surgeon, of Liverpool, acting on the hint which we lately put forth in THE LANCET, has just published " A Letter to the mayor, widermen, and councillors of the re porations, on the necessity of electrical medical coroners," in their respective

"This," says Mr. Regerson, quoting from Junius. "This is not the cause of faction, or of party, or of any individual, but the common interest of every man in Britain."

The example set by Mr. Rogerson is excellent and most timely.

GOWER-STREET. - To the Editor .- Several students in the dissecting school beg to express their regret (in a form which will perhaps lead to a remedy) that the time of the demonstrator should be so much occupled with pursuits which prevent him from giving to the instruction of the pupils all that attention which he formerly devoted so exclusively to his important duties. Our correspondents should have stated the name of the demonstrator. Complaint should be made in the quarters whence the appointment is obtained.]

SIR CHARLES CLARKE, we are happy to be able to state, is one of those distinguished individuals whose name is to be placed on the list of Metropolitan University Commissioners. His liberal principles and his being altogether unconnected with any school or intriguing faction, eminently qualify him for this distinguished honour.

(From a Correspondent.)-Dr. W. Cum-MIN. in deference to the exasperated feelings of the students and general practitioners, is about to relinquish his connection with the Aldersgate-street school.

CORRESPONDENT .

The letter respecting the meeting at St. Thomas's Hospital reached us, and it was designed to be inserted, but on receiving a copy of the following resolution, in which the students at that institution express their strong opposition to the proceedings of the Apothecaries' Company, we saw reason to doubt the correctness of some of our correspondent's inferences. The resolution says, "That this meeting regrets there does not exist a second examination for medical pupils, and that second examination a public one, to which any rejected candidate might appeal, as this would at once silence the murmars of incompetency, and destroy the possibility of private injustice. That this meeting also strongly disapproves of the principle of self-election and irresponsibility in medical corporations. "W. WEGG,

CHARLES EDWARD BLAIR, Sec."

Mr. Samuel.-It is not on Fri ay week, but on Tuesday next. There will be no speechifying on the occasion.

LECTURE XIV.

RAMOLLISSEMENT OF THE NERVOUS CENTRES.

GENTLEMEN, - The lesion now well known under the name of "ramollissement," or softening of the nervous pulp, is characterized by the following

Anatomical Appearances.

The first and essential character is a dimithe nervous pulp seems to have taken a as you can readily conceive, present itself latter, though softened, retains its accus- able, in the Archives Générales, t. 7, p. 52. tomed form and organization; the change is striate, concern will observe the medulary misrior of this portion of the and the several anatomical peculiaritite. If the optic thalami we can recognise its t although softened. s and are not confound-In a second degree of ramollissement, the consistence of the nervous substance is still more considerably dimi-

and the same of the same of the

degree, texture, hitherto unchanged, is more or less modified. The cerebral substance is broken down into a soft homogeneous mass. of the consistence of " stir-about." If water be poured upon the brain in this state. the nervous matter is easily separated from the membrane which envelops it, and forms numerous flocci that are suspended in the fluid. These fine, minutely-divided portions of the nervous pulp give a lactescent colour to the water, which might be mistaken for the effect of an admixture of pus; but it is not pus. The floating whitish flocci do not depend on the presence of purulent matter, because exactly the same appearance is produced when a portion of putrefied brain is deluged in water. Lastly, the nervous pulp may disappear altogether: we find no trace of meduliary substance, which has become altogether liquid, without the slightest consistence or texture. Of the cerebro-spinal substance, nothing remains but the vascule-cellular web, which in a normal state is masked by the nervous matter, and of which it seems to be the primary rudiment. In a few cases the softening ia carried to such a degree as to produce an actual solution of continuity: not only the nution of the normal consistence, in which nervous pulp has disappeared, but the cellular tissue just alluded to. M. Rullier has tendency to pass from its solid to a liquid described a remarkable case of this latter state. The lesion, thus characterized, may, kind, where the cervical portion of the spinal marrow was completely separated under a great variety of degrees. Some- from the dorsol, nothing being left but a few times the normal consistence of the nervous fibrous filaments suspended in a fluid. M. pulp is very slightly diminished, and the VELPRAU records a case, still more remark-Here the medulis oblongata was separated appreciable to the touch, but not to the from the pont in the most perfect manner; eye. Thus if the lesion occupy the corpora not a trace of fibre existed between them. and even the membranes themselves had disappeared.

Thus you see how the lesion whose history we now study, may present itself with various degrees of intensity, from a slight modification of consistence, where the original form and texture of the nervous substance remain unaltered, to that extreme degree in which it has returned to its primitive and liquid state-to the homogeneous and the sectioning is appreciable on faid that fills the membranes in the earlier on of the part. In a third period of fetal existence. In some cases

the change from its normal consistence is so tomore characters. These necessarily conperfect, that it would seem as if the different acts of nutrition had retrograded, and led back the nervous substance by insensible modifications to its primitive condition of liquid. Ramollissement of the nervons con tres may present itself with the simple character of loss of consistence, unaccounpanied by any other lesion; but at the same time that the nervous pulp is softened, it may be attended by various modifications of colour, which we can arrange under three distinct heads.

In the first place, rantollisement may exist with a normal coloration of the nervous substance. The softened portion is neither. more pale nor more injected than is natural.

In the second variety, we find the nervous pulp deprived of its normal colour, and of a dull white tint, and, as it were, affected with anemia. The colour sometimes resembles that of milk, or is more bright and resplendent; this is particularly the case when the lesion occupies the gray substance of the brain or spinal marrow. It is a circumstance which you should take particular sent itself, not with injection and other characters of inflammation, but with a perfect decoloration. On the other hand, if the ramollissement be confined to the medullary substance, we more frequently find it of a normal colour.

In the third variety, ramollissement is attended with an increased injection of vascularity, giving rise to various shades and tints, from a slight rose to deep red or of the head, chest, and abdomen, in the

mahogany brown.

Ramollissement is also from time to time ramollissement coexists with sanguineous at other times insignificant and disseminated from all other lesions of the nervous centhrough the altered pulp. The lesion how- tres, we shall now point out the different ever is by no means a necessary, though it may be a frequent consequence of ramollissement; it depends on an irritation of mass is no longer able to support the fiver vessels; these latter become over-distended, their parietes give way, and the blood is effused in greater or less quantity, according ment may be partial or general, the fair to the importance of the injured vessel.

Finally, we may meet with purulent matter, either infiltrated, or collected into an

same lesion, but an assemblage of lesions few acceptional cases; partial par differing widely from one another in any mentioney, as we have just said,

character everal varieties of the disease, and the disease and to open ramollisement with declaration, to the disease are the conditions less different, and as are the causes which produce tiem. Officere, there are cases, where no single organ has been found in a state softening, but where all the organs and ties sues of the body have been more or less ramollified where all the organs present a Are we to attribute this state to an universal inflammation? Are we to say here that the whole body is but one phlegmon? Absurd. Every rational physician, instead of pushing the doctrine of inflammation to this ridiculous extent, will frankly avow that there are lesions of whose nature and cause we are still completely ignorant. I call to mind. on the instant, an example which may serve as an illustration of what we have just advanced. A student of the Polytechnic School was seized with symptoms of the disease which nosologists are agreed in callcare to remember, that softening may pre- ing "typhus suraigue" (the worst form of typhus fever). The disease was very rapid in its course, and after death we found all the organs, particularly those abounding in parenchymatous tissue, reduced to a state of perfect bouillie, so soft that the least touch crushed them in pieces: the different muscles were softened in the same way. The muscular tissue was crushed down on presblood, with an exaggeration of normal sure, like a portion of brain. Are we to suppose that all the muscles, all the viscera present case were affected with acute inflammation? Are we gratuitously to adopt accompanied with certain lesions which we this latter idea, in the case now alluded to in shall briefly enumerate. Thus we sometimes order to please those who see nothing in find the softened nervous pulp more or less ramollissement but an effect of inflamma-infiltrated with scrosity. In other cases tion?

Having thus endeavoured to lay before effusions, which are sometimes very con- you a concise history of the anatomical chasiderable, in proportion to the softened mass, racters that distinguish ramollissement

Seats which this Lesion may occupy.

Ramollissement may have its seat in any the nervous substance, or sometimes on a one point of the nervous centres, either in cause purely mechanical. The softened that portion which is contained within the cavity of the cranium, or in the prolongstion, without the skull, which is denound nated the spinal marrow. The remailings lesion is much the more op softening of the comment abscess, in the centre of the softened nervous substance.

Thus you see a variety of cases presenting
to our view, not only different degrees of the lesion is rare, and presents used only is a

in the brain, or in the spinal marrow and in the first great distinction according seat of the lesion. At the critician with find any part at the convolution, that without the theory of the hemispheric, the deeper state parts of the hemispheric, the deeper state of the crebellar ; the deeper state of the crebellar ; the crebellar is the crebellar in the crebellar in the crebellar is the crebellar in the crebellar in the crebellar is the crebellar in the crebe parts in which it is most frequently observed are the same where hemorrhage also is most common; for example, in the corpora striata, the optic thalami, and meighbourhood of those two gamelton Let us first examine ramollissement when seated

In the Hemispheres of the Brain.

Here the lesion may be confined to a small point of the convolutions, attacking cither the superficial layer of the cerebral substance, or having its seat in the deeper parts, immediately beneath the convolutions; either of the two layers now mentioned may be engaged in the discuse, independently of one another. When the superficial layer alone is softened, it requires some attention not to overlook the existrace of the lesion, which may easily escape your notice; in these cases the cortical substance is raised up with the via mater, which cannot be detached from it; it is generally more injected than hatural, but sometimes the softened nervous pulp adherent to the membranes is very pale, and colourless.

Ramollissement may, on the other hand, respect the superficial substance, and attack the nervous mass situate immediately beneath the convolutions; or we may find it still deeper, in the centrum ovale, or in the nervous substance which forms the roof of the lateral ventricles; this latter mass may be softened in totality, or the ramollissement may occupy merely a few isolated points of small extent, and it is remarkable that this latter lesion, though apparently so insignificant, may sometimes give rise to symptoms just as grave as when a whole lobe is softened.

In some cases we find the softening confined to the optic thalami, the corpora striata, or one or both of the medallary protubecauses contained in the anterior borns of the lateral ventricles (cornua ammonis); the optic thatami are sometimes softened on the surface only; that white medullary layer tradica trey are enveloped, no longer exto reduced to a kind of fluid pulp, The requirement of the state of the pure of the state of

more the servous pulp which forms the pa-debie of the lateral contrictes; in many though we have found a layer of nervous ester, softened, sad quite diffuent, spread over these parietes, and at the same thes a quantity of serous fluid shed into the

The central white parts of the brain (the corpus callosum, septum lucidum, and foruix) are also the seat of ramollissement, and this not unfrequently. Here, as in the other parts we have enumerated, the softening may be either general or partial; in some the ramollissement is so extensive, and carried to such a degree, that all these central parts are reduced to a fluid state, and nothing remains in their place but a substance of a homogeneous nature, little more consistent than jelly. The septum lucidum and fornix are more frequently found softened and reduced to this "bouillic," than the white mass constituting the corpus callosum; this latter body often preserves its normal consistency when the fornix is reduced to a mere pulp, and breaks down under the slightest touch, and we may remark that the pillars of the fornix, especially the anterior, are commonly less softened than its body.

Ramollissement of the septum lucidum and fornix coincides in a very great number of cases with an effusion of scrous fluid into the cavity of the lateral ventricles; the nervous substance is then sometimes reduced to such a degree of diffluence that we find nothing but a number of flocci, floating here and there in the serum which distends the ventricles.

Behind the parts we have just mentioned there are others that occasionally are the seat of ramollissement, but not so frequently as the brain, strictly so called. Thus we have examples on record where the mesocephale (pons varolii), the pedancles of the cerebrum and cerebellum, and, lastly, the cerebellum itself, have been seen more or less softened.

The Cerebellum and Spinal Marrow.

In some cases the whole mass of the cerebellum has been found in a softened state. in others the disease is less extensive, and we observe only a partial ramollissement, occupying one or more points of its substance.

Finally, ramollissement may exist in that part of the ccrebro spinal axis which is placed out of the cranium; several cases of softening of the spinal marrow have been described: sometimes in its whole extent: at others, and much more frequently, in a limited portion. The two substances which compose the spinal marrow may be softened. either together or eparately. Thus, for ex-Again, we find, occasionally, softening of ample, it may attack the gray substance other party of the nervous centres; thin, it alone, which occupies the interior of the in not unconfident for rampilingment to occupie the alone, which occupies the interior of the in not unconfident for rampilingment to occupie the allouid pulp, and hollow

axis. The whole brain and spinal marrow are simultaneously reduced to a liquid pulp, in which all trace of organization is lost. BILLARD has described ten cases of this kind, where softening of the whole brain coincided with a similar state of the spinal marrow. Finally, in the totality of the cerebro-spinal axis we may have only a single point softened, or the lesion may affect several distinct points at the same time; it is thus single or multiple. In the hemispheres it is often double, and it may be formed, either at the same time or gradually, in the brain, properly so called, and in the other parts of the nervous centres.

What are the Causes of Ramollissement

of the spinal marrow and brain? To complete the history of any disease we must produce it, with the same care that we in- this lesion the subject of special research, vestigate its symptoms or point out its treat- we should soon have as many cases recorded ment: but the causes which give rise to of softening in the adult and the child, as softening of the cerebro-spinal axis are very we now possess of cases in the aged. Thus, little known. Indeed, the only one whose while attached to the hospital of La Charité existence we can consider as actually de- (which receives patients of all ages indismonstrated, is external violence, and in these criminately), I observed several cases of cases the ramollissement is an immediate softening of the nervous centres in indieffect of irritation or inflammation. In viduals from seventeen to twenty years of cases where we can find no trace of irritation, where the nervous pulp, far from being the disease is frequently seen, though we injected, is, on the contrary, decoloured, and have no statistical report on which we can where the whole lesion consists in a simple diminution of cohesion, in these cases we must acknowledge that the present state of shows that ramollissement may exist to a the science does not permit us to explain the cause of ramollissement.

Softening of the nervous centres exists at all

Periods of Life.

It has been observed immediately after birth, even before birth, as a disease of the fetus in utero. Cases of ramollissement in the adult are not rare; in old persons they are frequent, and hence we may conclude that this lesion attacks individuals of all ages. from infancy to extreme old age, from the child of one month to the decrepid invalid of 80 or 90.

Is ramollissement the same at all ages, does it present itself more frequently at one period than another? We have just shown that the existence of ramollissement at all ages is a fact placed beyond doubt by the observations of LALLEMAND, ROSTAN, BIL-LARD, and ourselves. However, we cannot but admit that it is a lesion more frequently found at an advanced age than at any other period of life; but if you ask on what data we establish this proposition, if you desire

out the artificial canals of which we have specific attacked, we cannot give you a spoken when treating of atrophy of the proving centres. In examining the nervous centres.

Instead of being partial, a lasion which is on ramollisenesses that they wous centress by far the most common, ramollisement you will find a great military of cases occupy the whole of the cerebro-appeal spring in old persons, but do not appelled. from this that the disease is almost sively confined to old age. The cases of ramollissement hitherto published concern principally individuals advanced in life, because their authors were attached to, or studied in the hospitals appropriated to the aged and infirm." Thus, in M. Rostan's work on samollissement, you will certainly find the majority of cases reported belonging to old people, because M. ROSTAN was attached at that time to the Salpetriere, and all his cases were taken from that hospital. Indeed, we have no extensive collection of rases observed in any other establishment. The work of M. LALLEMAND is an excellent one, but his observations and deductions are chiefly founded upon cases reported by various authors which he has assembled toplete the history of any disease we must gether. It is probable, then, that if the endeavour to ascend to the causes which physicians of other hospitals were to make age. At the hospital Des Enfans Maludes determine the proportion of cases. Finally, as we have already remarked, M. BILLARD very great extent within the first few days after birth. Let us now turn to a consideration of the

Symptoms which accompany Ramollissement of the Nervous Centres.

Here, indeed, our task is a difficult one. To convert particular signs into a general description, to follow up the connection of cause and effect through a series of accidents, succeeding each other at every instant, replacing one another, or connected without any apparent order and regularity: to separate the various modifications of fun-tion which depend upon the complexity of ramollissement, from the passages really produced by the his to seize the traits of select through a multitude of on to throw them together, and ferm of whole a faithful resemblation. These points which, however difficult, we must no

The symptoms of ramollisesment (families with a certain degree of to know in what proportion the different ence, as the lexion may

Lesions of Intelligence

do we observe in this disease? The state of the intellectual faculties is a light or being the same in all cases of ramollissement of the brain; in the first place, we observe a certain number of examples, and they are by no means rare, in which the intelligence does not suffer any trouble whatever: the reason, judgment, memory, imagination, &c., and, in a word, all the faculties of the mind, are in a perfect state of integrity. In a second series of cases the intelligence is suddenly lost at the moment of invasion of the disease; this takes place when ramollissement commences by a sudden loss of consciousness, or by coma, as in apoplexy. At the termination of a few days the intelligence is restored, either perfectly, which is rare, or imperfectly, the patient remaining more or less dull up to the moment of death.

In a third series of cases the intelligence is modified from the beginning to the end of the disease, but the mental faculties are never completely lost, as in the former cases; here the intelligence is obtuse, dull; the various acts of the mind are performed with slowness and difficulty; the patient has that oppressed and stupid air which often marks the presence of typhus fever; when spoken to, they answer slowly and uncertainly; the memory is weakened, and their ideas are somewhat unconnected, or they fall into a state of constant sleepiness, which is sometimes one of the most striking phenomena of the disease.

delirium results. according the intervening periods. In some case it makes, its appearance at the state of the makely. In other the motility, then, like the intelligence, may undergo various modifications as a result of ramollissement of the creek at the mispheres. The lesion may be gradual or mispheres. The lesion may be gradual or motion or with the first for those cases in which loss a form spitialist to constitute a true mental signstification. Some netterts are seized with a

The different conditions of intelligence now pointed out may exist by turns in the body opposite the lesion; the hand, for ex-

different portions of the cerebro-spins aris; turned in a perfect state a few hours before and hence, according to the practice to least, although it had been previously have hitherto followed in the present course, we shall follow the disease of the cerebrant's the central parts of the disease. Thus you see by wast a variety of lesions of intelligence of the cerebrant's the central parts; and in the appearance of the brain is accompanied to the sease functions of the brain; it is disease. Thus you see by wast a variety of lesions of intelligence are the great functions of the brain; it is disease. The present that they cannot in any way serve to aid as in our diagnosis of the disease. Perhaps they may depend on the seat of the lesion; they may depend on the seat of the lesion; perhaps they are modified by its intensity, or by individual dispositions of constitution; perhaps various troubles of intelligence may be caused by different degrees of congestion which coexist with ramollissement, or can only be explained by a special disposition of the nervous centres, which, though suffering under one and the same organic lesion, yet are capable of manifesting the effects of this lesion by functional modifications of the most various kinds. However. as we have already said, it is not rare to find ramollissement passing through all its periods without having once given rise to any trouble of the mental faculties. We have frequently seen examples of this kind, but, on the other hand, it is more common to find the intelligence more or less obtuse.

Lesions of Motility.

The movement is injured in a much more frequent and constant manner than the intelligence. Exceptions do, indeed, exist where we find no lesion of motility; but these cases are very rare, and we may lay it down as a general principle that modification of motility is the lesion which characterizes most specially, softening of the brain. What is this modification? In what does it consist? How does it manifest itself? Nothing would be more convenient for the practitioner, nothing would contribute in a greater degree to render medicine an easy science, and to smooth down the difficulties which now beset us, than the discovery of an Finally, in a fourth variety, the intelli- invariable and constant connection between gence is so far disordered and troubled that certain symptoms and certain lesions. Thus, This is particularly ob- some authors contend that ramollissement served when ramollissement commences as always gives rise to muscular contractions; an acute malady, or is accompanied by any of others contend that contraction ends in the symptoms that characterize encephaliparalysis. But, unfortunately, nature does tis, or acute inflammation of the cerebral not always follow the same route; if we meninges. This delirium may exist in a have contraction of the muscles in many constant manner, or only manifest itself at cases of softening of the brain, there are intervals, the intelligence remaining quite certainly a few in which this phenomenon

of motion comes on in a slow and gradual manner. Some patients are seized with a weakness of the limbs on the side of the same individual, and we have seen cases ample, has lost its accustomed force, and where the mastel faculty has suddenly re- cannot grasp an object so firmly as before. The whole arm seems heavy of the the drags along in walking. This commence ment of paralysis gradually suggested with at length the patient is complainly depriting of the power of wotten on safe side of the body. We have frequently had superfusion of witnessing this ourselves, and is cause of this kind we may distinguish this weakness of limbs produced by rampellissement of the cerebral substance, from the language time the weakness, for in effusion of hood into the substance of the brain, the paralysis is generally brusque, sudden, instantaneously produced, whereas in rampellissement we observe quite an opposite fact; we first have simple weakness, and it may take a series of years before this terminates in perfect loss of metton.

In other cases the paralysis appears sud denly, and does not pass through the different degrees we have mentioned; the patient saddenly loses the power of moving his limbs, which are completely paralyzed in a few moments after the commencement of the attack. Here ramollissement bears the greatest resemblance to cerebral hemorrhage, and it is absolutely impossible to distinguish the two diseases at first from one another. In the state just mentioned, several cases present themselves; thus, audden paralysis may seize the patient, without being accompanied by any other morbid phenomenon: the patient is simply deprived of the power of motion in one or more limbs, but no other function is deranged or modified. In other cases this simple paralysis is replaced by convulsive movements, which persist for a greater or less period of time, and then terminate in paralysis. The convulsions generally occupy the side of the body opposite the softened hemisphere: they sometimes mark the commencement of the disease, then cease, and give place to contraction or paralysis. In other cases they manifest themselves at a later period, The convulalternating with paralysis. sions, instead of being confined to one side of the body, may be general; both sides are equally affected, and in these cases you will often find the cause explained by a double lesion of the brain, both hemispheres being softened at the same time. Finally, instead of occupying the side of the body opposite to the injured hemisphere, the convulsions may affect the limbs on the same side as the legion in the brain. It is not now the place to enter into the considerations to which this latter fact is calculated to give rise: we can only observe, that in all cases where these convulsions exist, or where convulsion, alternating with paralysis, presents itself, we may have reason for thinking that another disease than simple he morrhege exists; we may be justified in attributing the lesion of metility to ramolling ment of the cerebral hemispheres.

INFLUENCE OF THE HYDRIODATE OF POTASH IN MALIGNANT PUNGOUS AND CANCEROUS DISEASES.

are your attention this morning to the case of the servant man keogh, who lately died in Ward No. 6. It is, in many points of view, full of interest. It affords a good example of one of the most malignant discases to which we are subject, of the insidious manner in which such diseases may commence, of the difficulty of distinguishing them at their origin, and of the sad consequences that may result when their nature is misunderstood; but above all, it seems to demonstrate, as far as one case can, that a remedv, the hydriodate of potash, with which we have been only of late years made acquainted, is capable of exercising on such diseases a most remarkable influence. The general power of this medicine is, in my opinion, as yet underrated, and, perhaps, because its mode of administration is not understood. I shall have many opportunities of demonstrating this to you as soon as I enter on my clinical lectures on the venereal disease, when I shall give you the result of nearly three years' clinical investigation on the power of this medicine in syphilis. Whether the remarkable change which we witnessed in the case of Keogh was owing to the influence of the hydriodate of potash, I allow, admits of a doubt. A single case is quite insufficient to establish a fact of this kind. but it is amply sufficient to induce us to investigate the subject further; and if it should turn out to be a fact, that this remedial agent possesses the power which I have reason to believe it does pomess, there open to our view a view feld of bu the period is not distant when we able to control by medicine one of the diseases, which in these within the observation of

Case of Keogh.

In all other parts, the surrounding skin presented a Kealthy appear ance, excepting between the timour on one side, and the pents and scrutnin on the other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing with an occasional darring sense-other, and there it was livid and very missing the parts, which distressed him

The fungus, or tumour on the penis, was seated on its right side and under part, and was not less than three inches in diameter: It resembled in its form and colour, in a the groin. It was, however, of a firmer consistence and paler colour. It was rounded, and its circumference overhung the edge of the skin. Its surface was irregular, presenting numerous depressions of a small the depressions were filled with a clear ichor.

There were, also, as you may remember, on the common integuments of the penis, two other diseased spots, of a smaller size, one on the right side, of the magnitude of a large pea, of a whitish pulpy appearance, considerably elevated, and the skin mounting at its side, so as to reach the level of its the penis, and of the diameter of a farthing. One portion of its surface was sloughy, or pulpy, and another was covered by apparently healthy granulations. This diseased patch was continuous, at one side, with the larger fungus on the penis, and in every other part it was surrounded by skin which had a healthy colour, but was raised into a kind of welt, which thinned down as it approached the immediate edge of the sore.

The integuments of both penis and scrotum were greatly thickened, and of a crimson colour, with a tinge of lividity. The scrotum was elongated and lax, and was kept constantly bathed with the discharge which flowed down from the fungous masses. The spermatic cord at the right or diseased side was as thick as a finger, but the same part on the left, as well as the lymphatic glands of the corresponding groin, were free from enlargement. Besides the discharge which was effused from the surfaces of the tumour, and from their circumference, there was a

days, I believe he fell under my care, and I have been informed that when he was admitted the immoure were not more than very striking manner, the larger tumour in half the size which they were when I first saw him; that the skin surrounding the one in the groin was of a livid colour, very tender, and presented anmerous small varicose veins distributed through its structure; that the surface of the tumour was insize and a larger hollow in its centre. All sensible and tubercular, or very much of the form of a hunch of hydatids. I have been also informed, that it presented (probably in consequence of the manner in which the edge of the skin was hidden by the overlapping fungus) such an appearance as to lead to the supposition that the disease was seated in the integuments rather than in the subcutaneous parts, and that it did not surface. The second was on the left side of resemble either fungus hamatodes or cancer, but was, in appearance, like the fungus which often grows from a testicle which has undergone chronic inflammation and suppuration.

It is, in general, very difficult to obtain a satisfactory account of the origin and progress of a disease which has been some time in existence; but as all the circumstances of this case were such as to make me very desirous to ascertain with accuracy its history, I took considerable trouble on the subject. I interrogated the patient and his wife separately, and made some inquiries from persons who had seen him in an early stage of the disease. From these sources of information it appeared that up to about sixteen months ago, at which time he was thirty years of age, he had a perfectly healthy constitution, that he never had contracted any venercal disease, except one about five years ago, and that was not fol-lowed by any secondary symptoms, that since then he had been manifold, there his habits had been many windled that he and from their circumference, there was a coplous puriform discharge from an opening or aft in the front of the scrotum, which led into the cellular tissue, as well as from the orifice of the swelled prepuce.

He was very rate and number or circum, which her long after the prothe orifice of the swelled prepuce. that about sixteen months ago a small vated sore, or livid spongy, wert, was served on the right side of the inner surface

He now applied at an hospit he got black wash and griped him very much, and worse. He next consulted in geon, who saw him at his own home, from whom he got pills, which he believes were mercurial, but they did not make his mouth sore. Not finding himself improved, he went into an hospital. Even at this time he could denude the glans penis, and the tumour was neither very large nor discoloured. He was now, unfortunately, put under a mercurial course, which excited much inflammation, and phymosis in consequence ensued. The tumour in his groin increased, and became red. An ulcer now formed on the outside of the inflamed prepuce, opposite to where the wart to which I have alluded was placed, and through this ulcer a fungous mass quickly protruded. The tumour in the groin soon after increased to the size of a goose-egg, and was still remarkably hard, but after a time it became irregularly soft, and of a livid or crimson colour. At this period, finding himself much worse, he solicited his discharge from the hospital, and, soon after, the skin covering the tumour in his groin gave way, and a fungus protruded. He now placed himment until he was admitted into this hos-

When I first saw this patient, I asked, "What has been done for him since he came into our hospital?" "The parts have been covered with a common poultice, and creosote has been administered internally," was the reply. That no advantage had resulted was evident, for the disease had doubled its dimensions since his admission; his hectical symptoms had rather increased; he

he spench which was about hime He still, sible, and, an the whole, experienced at the be justined in trying any time a great shock. Soon after this his affords a ray of hope; a kind of case which time a great shock. Soon after this his affords a ray of hope; a kind of case which Ettention was attracted to his right groin, demands, in fact, from every man anxious where he felt a small firm kernel. This grato extend the boundaries of his art, a trial, this proced limits, of empirical treatment; the for remedies which we know to possess the power of influencing the system to see the syste they may by their action influence the dis-east. We are often, indubitably, obliged to act in this manner. How frequently are mercury and arsenic given upon no better foundation! I had, as you know, been trying for a long period, and in various cases, with remarkable success, the hydriodate of potash. Come, said I, let us try it in this case. I ordered it, but with scarcely a ray of hope that it would in any way control or influence the morbid actions going forward. It was given to him in the dose in which I commonly administer this medicine; that is, seven grains three times a day, in an aqueous solution. He commenced on the 9th of October; on the 12th I observed, on going round the wards, a decided alteration in the style of his countenance. He looked, comparatively speaking, tranquil. He told me he had had a better night than any since he had come into the hospital, and that the pain in the parts was much diminished. Could these changes be owing to the hydriodate of potash? I reflected with myself. I could not, I confess, a fungus protruided. He now placed him-feel that they were. This medicine was, self under a country peasant, who gave him however, continued. I saw him daily, some-" herbs," and he remained under this treat- times looking at the tumour, and sometimes not, but I did not notice any remarkable change further than that which I have just mentioned, that is, in the state of his pain, until the 18th, or nine days after he had commenced the hydriodate of potash, when he complained very much of soreness of his throat. On the 20th he complained still more. I examined his throat, but could not observe anything to be the matter. Presunning that it was a state of throat analogous to that which not unfrequently occurs seemed miserable in his feelings; his nights from the employment of the hydriodate of were resteasy and his pain was great. I contained the supported him to discontinue this contained the southern and to take a mixture containing recting the southern to be pat on the part, wet with a weak solution of the chlorate of limes I also ditter the support to me to be a little smaller. usion of the chlorate of limes Lako dl they appeared to me to be a little smaller. draught, and, during the day, my fa suspicion, for the decrease was, if any, not tranger, and, during the day, my is

side to the forces. His urine on this

day was loaded with the hydriodate of On the 24th of the stants, or formers, days after he had committed the lydisolate of potash, the strengton is the state, the tumour, as you may restembly, and the greatest surprise. It was estimate the greatest surprise. It was estimate the greatest surprise. It was estimated the greatest surprise. It was estimated to each all its former magnitude, and the surprise was no pain in the part, no surrounding fandmandion; the dull heavy sensation and the shooting pains had entirely ceased; he appeared quite tranquil; his nights were spent comfortably; his appetite continued, and, on the whole, there was so remarkable a change, that I was nearly vain second to suppose it possible he might recover. I now directed the hydriodate of potash, at trace of which was will visible in its urine, to be again given, but in half deeps only; and to prevent the return of the last of throat of which he complained with the of throat of which he complained with the other of the should continue his quintee mixture, taking it before, and the hydriodate of potash after his meals.

Under this treatment his throat continued easy, the decrease in the size of the fungi progressed, their middle portion crumbled away more rapidly than the circumference. and the diseased mass in the groin now assumed strikingly the appearance of an ordinary carcinomatons sore. The comparatively happy and tranquil state which I have already remarked, persisted, and his appetite remained sufficiently good. But, notwithstanding these pleasing circumstances, his weakness increased, his pulse became more debilitated and thready. short, the disease seemed to be going off, and his strength to be, in the same proportion, declining.

On the 10th of November, at which time he was still continuing his medicine, the discased fungous mass had totally disappeared from several parts, and at these parts the surface had acquired the aspect of a phagedenic or sloughy sore, yet there was scarcely a blush of surrounding inflammation, and no pain.

The hydriodate of potash was now omitted, the sulphate of quinine was continued, and the diseased surfaces were covered with hot dressings of clemi and turpentine.

On the 22nd of November there was not a trace of the fungous masses; the penis seemed as if it had been amputated exactly between the fungus and the comparatively sound part. It, as well as the scrotum, was no longer either swelled or red. The size and inflammation of these parts had declined with the decrease of the tumour. The fungous mass in the groin had also disappeared, and a deep and dark excavation, of the size of a plate, occupied its place.

of the size of a plate, occupied its place. He was now sinking rapidly, yet he still presented an appearance of remarkable contentment, and exhibited an extremely

police sank to a pulse sank to

Astepsia.

I examined the nody six hours after death and made at the time a note of the dissection, which I shall read to you:—

"Extreme emaciation; no odema of the

"Extreme emaciation; no odema of the lower limbs; the transparency and thinness of the skin covering the arms and thorax, allows which of colour produced by the subject muscles to be observed, which gives very much the appearance, on the surface, of incipient putrefaction. The lower limbs are elightly stiff, but the muscles of the upper part of the body are quite free from rigidity

"The diseased surface, which had the groin for its centre, is fully seven inches long, and six inches broad. It is covered by a thick stratum of pulpy brown matter, which is easily scraped off with the back of a kuife. In thus clearing away the pulp, a portion of the anterior wall of the femoral vein has been removed. The internal surface of this vein, extending up and down for an inch from this part, is of a dark-brown colour, like the pulpy mass which covered the diseased surface, and is softened in its texture. At this part, and for some inches above and below, the vein is imperfectly filled with a coagulum, devoid of colouring matter, as far as the vein is discoloured; but above and below this, it presents the usual red appear-ance of such coagula. The femoral artery seems sound, yet the parts covering it are scarcely less diseased or softened than those which covered the vein. The cellular texture on the lateral and posterior aspects of these vessels, has, when divided with a knife, somewhat of a cartilaginous appearance. The femoral nerve does not appear diseased. The aponcurotic expansion of the external oblique muscle, as well as the fascia lata, are exposed, upon the removal of some soft brown matter which covered them, and their structure seems softened. This extensive diseased surface does not a pear to have any base, or, in other we the more subjacent parts do not ap eased. The extremity of the penis h removed, and the end of its the same soft or pulpy matter served in the grain. When served in the grain. Then the soft matter is rubbed off, the entire. of urwitten, the entremities of the cor-position and corpus covernogen, ap-mentaged at their ends, but without the all est aspect of thickening mas if there

drink and strict diet. In the evening the patient was select with violent delirium; the permissed all night: the child got out of Seed continually, and traversed the wards uttering loud cries; it became necessary to confine her in bed with the strait-waistcoat.

6. Dorsal decubitur; stupidity without prostration; the hearing is dull; the headsche persists; the conjunctive are injected; she answers shortly but correctly; the tongue is covered with a sort of clammy fur of a grayish colour; breath foul; deglutt-tion is easy; thirst excessive; complete loss of appetite; no nausea or vomiting; abdomen free from pain, and marked by two or three rosy spots; only one stool for the last second volume of my work on the venereal twenty-four hours; pulse regular and soft, 120 as in the ovening; the skin still warm and dry; the respiration slightly accelerated, is 36; cough; rale sibilant equally audible at both sides of the chest. The patient remained pretty calm until two o'clock, but she then commenced to sing, and disturbed the whole ward by constant cries; the de-lirium and agitation continued until the following morning.

7. The patient is now in a state of prostration; the face has an expression of stupidity, and the deafness is more evident; she answers slowly; the rose-spots are very numerous over the front of the abdomen and chest. The state of the tongue is the same as yesterday; no stool; pulse 120; respiration 30; a pain is felt under the sternum and in the abdomen; the cough CASE 3 .- Zoe Guilbert, 14 years of age of and rale sibilant are the same as before; the nature of the disease was now evident; the patient was ordered a bottle of Seidlitz water, to be taken in glassfuls every three

hours

8. The delirium has been just as violent as in the former nights; the patient has taken the whole bottle of Scidlitz water, which produced only two evacuations; the skin is now more dry than before, but not more warm; the tongue trembles when put out, and presents the same characters of

9. The evacuations have become more

of strength is now more marked; the tient can sit up in bed with speift dis pulse 124; respiration 48; cough fr rice subcrepitant on the right si chest behind, but no diminution of so Continue the Seidlitz Water, unEth with an Inflation of Marsh-mallows.

The delirium, which for the last ten days existed only at night, now broke out during the day time with great intensity. The patient left her bed, and ran about the want with a tottering gait, causing great

amongst the other children.

10. The number of evacuations is still 10. The number of asparition is at a till increased; some hars been passed involving tarily. The patient mays the abdomen is free from pain, but resolvent prossure causes a contraction of the states of the face, and evident suffering. The is new no delivium; the patient only that the head heavy. A discharge has taken added from the left ear, and the sense of hear the almost completely abolished; the rost pits still continue, but we do not observe in the sufficient in the continue. nue, but we do not observe any sudamina; the cough is less frequent; the respiration not so accelerated; pulse 120; respiration 24. Three Glasses of Beidlitz Water.

11. Less dolirium this night; the diarrhoes persists, and the stools are generally passed without conscioneness; the lips are dry and cracked; the tongue clammy, but without any crust; the abdomen is moderately sensible to pressure; the points most sensitive are in the epigastrium and right iliac regions; pulse 124. Continue the Seid-

litz Water.

From the 12th to the 17th day, on which the use of Seidlitz water was suspended, the patient became gradually better; the pulse fell from 120 to 108; the skin lost its dryness. The delirium went off, and the sleep returned insensibly. On the 14th we observe a few sudamina on the neck; the stools are no longer involuntary, and the number diminishes by degrees; the slight pain which occupied the right side of the abdomen has disappeared.

18. On making the visit, we find the patient sitting up in bed; the expression of the countenance is now natural; the intelligence perfectly clear; the hearing no longer dull. The patient sleeps quietly during the night; the muscular force is nearly recovered. The patient can walk about, and she seems nearly as fat as when admitted into the hospital. The tongue is now moist and clean; the appetite good; abdomen free from pain on pressure; no cough; pulmonary expansion good; pulse now 108. The patient complains of severe pain in the right ear. Three Lesches behind the Ear; Broths.

20. A purulent discharge from the right ear has set in. On the 24th the patient got up for the first time, and took some solid han water affection almost. The state of convalencence progressed to the 28th, when she was select been described by systems

r and general malaise, without iting. These symptoms coninvalinatednext day benign, although the restinated. On the 5th of lever, which had fallen since returned, and persisted for two days. Desiccation is general. The patient was now vaccinated, but without any result.

15th of January she left the hospital . Com-

pletely bured

Care 4.—Part Concent, 8 years of age, orting Parts of a delicate constitution, was rought to the hospital on the 18th of November in a completă state of delirium ; on the following morning we ascertained that the child had been first days ill. The night had been passed in a thate of excessive agi-tation. He made water in bed, but had no stool. The child now lies in a state of stupor. The intelligence is dull; the tongue red and smooth; thirst great; febrile movement very intense; several rose-spots on the abdomen; but pressure scems to give little or no pain; the bowels are constipated. The physician ordered a bottle of Scidlitz water to be taken during the day; this produced six stools; one vomiting; delirium during the night.

20. The fever is now more intense; in the evening the pulse was 120, it has risen today to 130. The tongue, however, is not more dry; the abdomen is but slightly tender; there is a little meteorismus. quantity of eau de Seltz is reduced to three glasses. 21st. The stools are very frequent. and the abdomen is more painful on pressure than it has hitherto been. The febrile action is very intense. Suspend the Scidlitz Water.

From the 22nd to the 27th, the fever continues, and is accompanied every evening by a paroxysm, during which the patient's intellectual faculties are completely lost. The diarrhosa persists equally; two or three liquid stools every day. No active treatment is had recourse to. The physician is content with ordering a cooling draught.

28 We observe numerous sudamina on the neck and chest. The skin is now moist, and the pulse has fallen to 104; the patient passed a quiet night. During the following days the symptoms gradually declined. patient was allowed to take some solid fo charged from the hospital bereetly we

The above cas described lest me cannot be arrange

tacking children at a very early n life. However, the more we a eases of mildren, the of the truth of t by M. Grand of the third shildren salicet at all the diseases of adults, in addition, to certain maladies which po peculiar to their tender age. Thus, in the course of November last, we had occasion to observe the case of a long sight years of age, affected with a state of fistula at the root of the scrots result of an accidental lesion, in a gradual manner, like the flately by stricture in the adult. Another case, not less rare, presented itself on the 18th of December, 1835. A boy, fourteen years of age, was brought to the hospital in a state of extreme weakness; pulse 1:0; violent pain of the abdomen; twenty to twenty-four stools in the day. The patient died in a few hours after his admission, and, on examining the body, the abdominal aorta was found to be the seat of three large false aneurysms; the superior of which, placed nearly on a level with the kidney, had given way, to the extent of a couple of inches. About the same time, a case of cancer of the abdomen was observed in the "service" of M. JABRLOT, in a child six years of age.

The four cases we have detailed are sufficient to indicate the general characters of typhus in the child; the symptoms, indeed, seem to differ very little from those which mark the disease in the adult; there is the same prostration of strength, the same derangement of the intelligence without any sign of cerebral inflammation-in a word, the same tendency to adynamic and ataxic symptoms: however, the affection is, generally speaking, a much milder one in the child than in the adult; the mortality is much less for the former than for the latter, but the march of the disease is precisely the same, and after death we find the same letions in the intestinal consis-

A laverages, with quinine, is then therein up the rectum, and a few spoonfuls of Bordeaux or Halaga wine are given every now and then.

Bayner ocque is the only physician in vogue in Regiand since the publication of the mork of HAMMEON. The medicament he administers in preference to others is Scidlitz water. The advantage of purging, however, has appared very doubtful, especially in the few months, during which a tendency. Eyentery has prevailed amongst the pass. In several cases the administration as few spoonfuls of Seidenstein and the several cases the several case the several cases the several case the several cases the several cases the several cases the seve lew months, during litz water, determined severe purging and dysenteric symptoms, which eventually carried off the patient. It is hardly necessary for us to make any farther remarks on this subject, we shall therefore merely observe, in conclusion, that, on examining the bodies of children which have been cut off by this disease, we have never yet discovered the least trace of inflammation in the cerebrospinal system. The stupor, the delicium. and the convulsive movements, are merely sympathetic phenomena, and certainly are not connected with an organic change of the brain, yet how often do we see the whole attention of the physician directed to these symptoms!

P. H. GREEN.

APHONIA

OF TWELVE MONTHS' DURATION SUCCESS-FULLY TREATED BY

TONICS AND REPRATED BLISTERING.

To the Editor of THE LANCET.

Sia.—From the following case we see the necessity and utility of a sufficient continuance in any line of practice we may deem requisite in chronic affections. At an early period of the disease, the patient had been twice blistered and had also used tonic medicines, but unfortunately they had been discontinued too soon. If, therefore, the publication of this case in your valuable Journal be in the slightest degree the means of restoring to any other similarly situated individual

that faculty which places us to each oth in the relative capacity of social belogs, it object will be fully accomplished.

I am, Sir, yours &c., JAMES INGLIS, M.D., M.R.C.S.E. Castle Douglas, Feb. 23, 1836.

Jean Gibson, set. 22, of a healthy and rather plethoric habit of body, was three years ago seized with cholers, during the rage of that epidemic. The attendant surgeon using large doses of calomel for the removal of this disease, poured into her a double portion in consequence of a relapse. Ptyalism to a considerable extent followed, and she continued extremely weak for a long time afterwards. Recovery to health gradually took place; and she continued as ervant to a family in the neighbourhood, until, being exposed to the cold night air. about the end of last February, she contracted a cold, accompanied by a considerable degree of sore throat. On Saturday (the day following the exposure) she comlained more of the throat, and got hoarser towards the afternoon, which hoarseness continued to increase till the Monday morning, when the voice entirely left her.

In consequence of this attack she left her place and returned home; but feeling herself much better at the end of a fortnight she again entered service. For several weeks the throat annoyed her, but at length, without using any means. it got quite relieved, so far at least as pain was concerned. From that time to the present she has enjoyed good health, every function of the body being normally performed, with the excep-tion of that of the organ of voice. In the month of June or July she applied to a gentleman of considerable note, who, after trying the effect of several remedies, at last dismissed her with the consolation that the voice would never again be restored. After this, several medical men saw her, and had administered tonics, expectorants, acids, sarsaparilla, iodine, &c. &c.; she had also been twice blistered, but all with a similar result, so that the conclusion was that the profuse exhibition of calomel being the cause, the disease could never be remedied.

It was under these circumstances that during some part of the month of November she first applied to me. On reviewing her case, I considered that the mercury could not have been the cause, inamuch as two years had elapsed since its exhibition, whereas had it really been so, the effect would have been much sooner apparent. My opinion was that the loss of voice arose from a thickening of the laryngeal mucous membrane, and atony of the vocal chords, the gently employed.

Anticomparison of the vocal chords, the gently employed.

Anticomparison of the vocal chords, because paralytic, become and that if that could be overcome the anticomparison of the track of the week would be restored. For this purpose rot, being relieved by the application, we also the thight, nor by applications, we consider the thight of the property of the specific to the thight, nor by applications, we consider the thight of the purpose of the thight of the purpose. brane, and atony of the vocal chords, the I recommended repeated blisters alo larynx and traches, one every fifth or

After taking these sighs in pulv xviii. powders, and blistering three times, I thought I could discover some improvement, I therefore repeated them, with the addition of 9 of chinine, and ordered a continuence of the flisters. She remained nearly in the inine, and ordered a continuence of same condition, till after having taken the thirty-sixth powder, and having blistered six times, the voice was restored, and she now speaks with all that freedom and volubility which characterize her sex.

AMENORRHOLA.

A case of amenorrhous successfully combated by the application of sinapisms to the mammæ, is related by M. Hulin-Oniger. Secretary to the Medical Society of the Indre and Loire, in France, in the Revue des Journaux de Médecine for August last. The number of analogous facts are so considerable, that so doubt can remain with regard to the suitableness of the means in numerous cases of amenorrhoes, and now that their efficacy is rendered so unquestionable, it only remains to state the description of cases in which the sinapisms may be employed with hopes of success, at the same time indicating those in which this measure is contra-indicated; for we do not expect that all obstinate cases will be so treated with equal advantage. At present we shall simply give further circulation to the new fact which we have above mentioned, in addition to those which are already known.

Case .- Josephine B., aged fifteen years, of a lymphatico-sanguine temperament, and having a good constitution, had had her catamenia only thrice since her eleventh year. In the spring of 1832 she was seized with convulsive motions of the arms and wrists, in consequence of profound grief and sudden alarm. Some days afterwards she was unable to move the left arm, which, at the same time, was affected excessive sensibility, and so conti-two months, though antispensed cines and campborated liminests w gently amployed. Three menths of he leaches to the thighs, nor by light the anemoniated liniment upon the l

April 1833 she experienced a new attack of the legs, which diminition in the same had been seized with vocal in small quantities. It is the same of the year 1825, she had a most severage fact of negative tendings, and afterwards parallelle of the seizet nerve of the right leg. She was relieved by one blood-letting, but not cured

She was in this situation upon the Mind of February, when the repersary source that he attempted to restore the flagged the catamenia by irritating the mamme in the manner proposed by Dr. Mondière. Two cataplasms, prepared with five ounces of mustard, were applied to the outer and external sides, and also to the superior portions of the mamme. The severe pain which she experienced in about fifteen or twenty minutes after the application, forced her to remove these cataplasms, which reddened the skin, and rendered it very sensible to the touch. The next day she had a considerable flow of leucorrhoes, and the third day she had an abundant catamenia, which, instead of four, continued during seven days, as in the months of August and September. On the 3rd of April this person enjoyed good health, and walked out freely. The mammie are developed, and since the return of the catumenia she has grown in a remarkable manner. We think (adds the author of the case) that this salutary revo-lution was hastened by the augmentation of the vital activity of the uterus, and is attributable to the artificial irritation of the on the table. manunæ.

HOUSE OF COMMONS.

Murch 1, 1836.

MEDICAL WITNESSES BILL.

MR. WILKES said, that before the Honourable Member for Finsbury rose to make the motion he was about to submit to the House, perhaps the House would allow him (Mr. Wilkes) to present a petition on the subject of that notion. The petition was from Mr. Baker, a surgeon and apothecary, reliefsing at Hostbo, in which document the petitioner, made the following statement. On the Estimated Linky, 1835, the petitioner was requested to distance the post-morten massination of a person who was supposed him to be a missrance. He attended before the Capitals, who postponed the examination with the following day, in order that the grashmation might take place, and on the following day, the petitioner was requested to submit the contents of the stomach beingmysation, to allow which, the

inquest was again adjourned for three or four days. The analysis occupied several lacure of several days of this professional gentleman's time, and subsequently the potitioner gave his evidence, when the Coroser and the jury felt that he was entitled to remuneration, and unanimously expressed their approbation of the intelligence and talent he had exercised on the occasion, and their gratitude to him for the assiduity he had manifested, at the same time recommending to the parochial authorities that he should be paid for his professional attendance and labour, the ordinary charge for which would have been ten guireas. However, he only applied for three gui-neas, when the answer was, that they had no power to make this any compensation what-wer, out of any this lover which they had control. Under these circumstances the etitioner felt that the Legislature ought to interpose, giving power to the Coroner to award to professional men some remuneration when their time and talents were thus drawn upon. (Hear, hear.) He (Mr. W.) knew perfectly well, that by far the greater proportion of professional gentlemen were decidedly convinced, that for the ends of justice a remuneration of this nature ought to be provided. A petition was in the hands of his honourable friend, the member for Southwark, signed by several hundreds of the physicians and surgeons of this metropolis, in favour of that provision, and, undoubtedly, the case urgently required legislative interference.

The petition was then ordered to be laid

Sir John R. Reid said, that he also had a petition to present on the subject. It came from the medical gentlemen of Ewell. in the county of Surrey, requesting that the House would take into consideration the difficulties with which they had to contend as witnesses at coroners' inquests, and praying the House to provide a fair remuneration for their trouble. He entirely concurred in the sentiments expressed by the hon. Member who had just sat down (hear, hear), and he had no hesitation in saying, according to the view he took, that no individuals in society were so badly paid as gentlemen in the medical profession. (Cheers.)

The petition was ordered to be laid on the table.

Mr. BARCLAY said, that he also had had a petition entrusted to him for presentation from medical gentlemen in a town in the county with which he was connected, and which he regretted much he had not brought down with him to present on this occasion. The petition was to the same effect as those which had just been presented, and his own opinions upon the subject-entirely concurred in those which had alpeady been expressed. (Heer, hear.)

No. 653.

Mr. D. W. HERVEY seld, tink he l petition to present, signed by \$25 games men, all of whom were dissippossed for their professional eminence in this metropolis. Indeed, he should shink it invidious to select any names from amongst them, I can assure the House the Proposent de-except merely for the purpose of stating. Suiency in the law is not so industrials to the that amongst others it was signed by the medical man as to the public at large presidents and the vice president of the (heer, hear), because it entirely defeats the Royal Colleges of Physicians and Suppens, object which the public have in view in up-Sir Astley Cooper, and Sir Anthony Car-lisle, who all stated that great inconvenience as well as great injustice had occurred, in consequence of the absence of a compensation to medical gentlemen who were called upon to attend at coroners' inquests. He trusted that the bill, which his hon. friend the Member for Finsbury was about to in-troduce, would, under these circumstances, be successful in its passage through the House. (Hear, hear, hear.) He had also a petition to present, signed by sixty-five professional gentlemen, resident in the Borough of Southwark, to the same effect.

The petitions were ordered to be laid on the table.

Mr. WARLEY .- Sir: From the very favourable manner with which the House has been pleased to receive the petitions which have just been presented, I am sure I shall not have occasion to occupy your time for more than a very few minutes in explanation of the nature of the Bill which I wish to introduce. When, last year, the County Coroners Bill was before the House, the House will recollect that it contained a clause professing to provide for the remuneration of medical witnesses at inquests. which clause, however, shared the fate of the whole of the Bill, the Bill being rejected by the House; and, I think, very properly, for it was perfectly unsuited to the objects which the honourable Mover sought to attain. I am ready to admit that medical gentlemen may not, in some respects, he more useful when they attend as witnesses than others, but it should be borne in mind that medical men attend the Coroner's inquest in their professional capacity. They do not attend as casual observers of the event which may have occasioned the inquest; but as professional men, who alone ean give that information which is essential to the ends of justice and the basis of a true verdict. The duties which medical men sideration, and observe the anxiety of the have to perform are exceedingly important (hear, hear); they are very difficult of accomplishment, and very frequently attended even with danger to life. A postmortem examination is not to be conducted in haste, or without science and trouble. Many instances within my own knowledge have arisen where a post-mortem exam-

grered, obtained no kind of reserv-Corener baving no power to the alightest compensation. object which the public have in view in upof the most important offices in England, and almost the enly office to which the people have still the power of electing their own judge. Yet unless that judge be invested with the power to give compensation to medical witnesses, I do think that the Court has a sendency to become remost useless. (Hear, Lear, Lear.) When the Coroner calls a medical man before him, he has not the power of requiring the witness to reach a post morten examination, aithough the result of that examination may be the only disclosure which can enable the jury to return a correct and faithful verdict. Within a very short period several inquests have been held in this metropolis upon the bodies of persons who have died under very extraordinary circumstances, and I may mention that quackery at this moment (hear, hear) is producing more victims (hear, hear) than it ever did at any former period. (Hear, kear, hear.) It is fearful to observe the consequences which flow from the advertisements of quacks with which the newspapers teem (hear, hear); and I should be glad, indeed, if his Majesty's Government would resolve on the removal of those disgraceful outrages upon society, hy preventing quack medicines from going forth to the public under the authority of Government stamps. At an inquest held a few days ago, the circumstances of which have excited great indignation, several medical men attended, all of them, of course, without obtaining compensation. Had they been selfish or mercemary enough to refuse to attend, or had they withheld their information as professional men, what verdict could have been returned? How completely might justice have been defeated on that occasion! And how frequently do similar instances occur! Now. Sir, when we take these points into conpeople to have faithful verdicts recorded. I do trust that the House will not refuse to grant that compensation as madded will-nesses which will be ensured by the paging of this bill. As I am sure, from what have observed to-night, that the principle the bill will be sanctioned by the House, shall not at present enter upon is det ination has necessarily been protracted through a period of eight or ten hours, and that legge be given to being in a bill to yet where the medical witnesses who conducted it, and gave evidence of the facts may attend as witnesses at covariant inquestion.

MR ATTORNEY GENERAL experience I will venture to Bill for the bringing in Member for Figures he Member for Risibury has now merced, with one favourable to this bill being brought in; he was very said that such a bill have to the bill being brought in; he was very said that such a bill have to the being brought in; he was very said that such a bill have to the being brought in by the hon. Member for Finstein has been obstructed in consequence bury would be passed into a law. (Hear, been given before a Coroner's jury. Jurios Hentber for Britipor had suggested, was either ser without that outdoor. sitter are without that evidence altogesher, carried tuto effect, a principle would be or, when it is obtained, the injustice of refus. refused which could not be satisfied in ing to award a fair and honourable remunes the quarter mentioned, from want of pro-ration is committed. (Honourable would per funds, in consequence of which the only suggest to the hon. Member in bring applications for remuneration could not be ing in this bill, to take care to have it so complied with to the proper extent which the framed that it shall not be made the means services of well-silucated medical men would of a job by the coroners themselves. (Hear, require. (Hear, Mer:) The hon. Member hear.) Coroners have before now made, a who had brought forward this measure job of their office; and unless care be taken ought to take the thin the subject of the best that a proper companishes will make a job of this by calling in a sation was previded in the bill. He (Sir medical Friend, and giving him a couple of G. S.) well knew the liberalty of the meguineas where there may be no necessity whatever for his evidence. With that caution against abuse of this kind, I certainly do think that where medical men are called in, on fair occasions, they ought to be pro-perly compensated. (Hear, hear.)

Sir Robert Inglis thought it might be desirable to know from what fund it was proposed by the bon. Member for Finsbury that the medical gentlemen should be paid? Was it proposed to throw the payment upon the parish or the county?

Mr. WAKLRY considered that it would be better not to enter into a consideration of may of the details at present, though he did not object to saying that in his opinion the two sources. On according the motion,

Mr. WARBURTON said that of course the hoa. Member for Finsbury would take care in the bill that professional gentlemen were paid for their attendance; but looking at cases where the talent of persons of superior information was called into action. where their materials and apparatus were required in an analysis, he should think that the compensation would fall short of what it ought to be, unless there was reference had to the expense of the education of the individual. (Cheers.) It seemed impossible that the parish could have refused to pay the petitioner in the case detailed by the hon. Member for Boston, but having refued. he would advise him to present him-self at the Home Office, and inquire if the justice of the country was to be defeated secure he could not afford to give his time Appliabous in the manner required, of whether a fair remuneration would be made to both. Until such a bill as his hon. Friend, the Remuneration would be made to both. Until such a bill as his hon. Friend, the reduced became the law of the land, he should certainly recommend medical with his property and attention.

e Home Office sir Gro. Beer, Aver.) so. Symical AND said that he was dical profession. (Cheers.) He believed that no class of individuals in society devoted so large a portion of their time, and underwent so much trouble, for the public, and for the poorer classes especially, and he was quite sure that neither the public, nor the legislature would raise any objection to a remuneration, on all proper occasions, being provided for such men (hear, hear); and he was quite satisfied that those gentlemen who devoted so considerable a portion of their time so liberally for the public good, would be satisfied with a small remuneration for attending at Coroners' inquests; but remuneration they undoubtedly ought to have.

The Hon. A. TREVOR (who was almost payment ought to come from one of those (mandible in the gallery) said, that he could not forhear expressing the great satisfaction he felt at the honourable Member for Finsbury having given notice of this important measure. All men must be agreed, that compensation ought to be provided for medical man who attended as witnesses at coroners' inquests. He knew no body of men whatever who were so essentially usetol to the public, or who did anything like so much good to the poorer classes of so-ciety (cheering), and they were entitled to all the consideration and assistance which that House could afford them. He did not entertain any great apprehension that a measure like this would be converted into any thing like a job. (Hear, hear.) From what he knew of the respectability of coroners in general, he could not persuade himself that they would attempt to disgrace themselves by converting such a measure into a means of abuse, even if it were in their power to do so. Still, if that were possible, he was satisfied that the object with which the hon. Member for Finsbury was about to introduce the hill, would greatly counterbalance any evil that could result from its operation in such a way. (Hear, required in Coroners courts, to suply herr.) He could not allow the House to grant leave to introduce a lift of this description, without appressing his most annion hope that it would be passed into a low

hope that it would be passed into a line.

Mr. Jenves said, that he was not about to make any objection to the introduction of the bill, he only wished simply to abserve, with respect to the existing law, that if a coroner desired to have the attendance of a medical man at an inquest, and issued his warrant to the parochial officers, calling on them to send a medical witness, and they did so, that medical winness, and they did so, that medical man would undoutedly have a claim upon them for compensation, which he could enforce. He believed that no doubt existed on this point, and if the hon, and learned Member, the Attorney General, would take the trouble of looking into the old law affecting the case, he would find it to be as he (Mr. J.) had stated.

Sir J. R. Rein was understood to say, that he did not believe that the petitioners whose petition he had laid on the table, did so understand the law, but, however that might be, it became the duty of the Legislature to put the right of medical witnesses to compensation beyond dispute, or diffi-

culty. (Hear, hear.)

Mr. Solicitor General said that he knew many cases in which medical gentlemen had been summoned to give evidence at Coroners' inquests, without being able to obtain any remuneration whatever. This was, undoubtedly, a great hardship. In some of the instances they had had to travel a long distance, and give up a very considerable portion of time. The bill now about to be introduced, was one in which the medical profession at large took a very great interest; and although, perhaps, strictly speaking, as had been stated by the hon, and learned Member opposite (Mr. Jervis), medical witnesses might, at present, have a legal right to claim compensation, yet he knew of no means by which the law could be enforced, and as the bill of the hon. Member for Finsbury seemed to be admitted by all to be only a matter of right and justice to a most meritorious class of persons, he sincerely hoped that that hill would meet with no obstruction in its progress through the House. (Cheers.

Mr. PLUMTREE said, that the bill should havehisutmost support. Asthehon. Member for Finsbury was himself a medical gentleman, he had no doubt that the provisions of the bill would be judiciously frassed, and he merely wished to express a hope, that it would be distinctly provided whether the compensation was to come from the parish or the county, that there might be no difficulty or delay experienced afterwards in obtaining the remuneration to which the witnesses would be entitled.

Mr. Wakley said he thought that what is most approved of the competitors had been stated with respect to the law of the prize; every dressord three most the case by his honourable and learned standing is eligible as a caselidate fee.

im (Mr. Jervis) would be found witness, but it was equally a medical man, it we produce as the most open the body. I will give no testimony respecting a post-mertem examination; respecting a post-mertem examination;" and the coroner has no power whatever either to compel him to make the examination, and state his opinion on the cause of deth. or to commit him for a contempt of court. Now he (Mr. W.) wished to give the coroner more power; but, at the same time, as a set off against that power, he wished to give the medical man a due compensation. (Hear, Acer.) He would at the same time assure the honourable Member (the Attorney-General), and the House, that it would be his anxious wish to guard against the possi-bility of jobbing under the provisions of the measure, because jobbing was what he most cordially detested. (Hear, hear, hear,) He knew that in Ireland there had been much jobbing carried on under the Coroners' Bill, where five gaineas had often been paid unnecessarily under the Act, but he would take care to guard against such an abuse here. With reference to what had just been stated by the honourable gentleman opposite, he could only say that he should be perfectly satisfied with the decision of the House as to whether the compensation should come from the parish or the county. (Hear, hear.)

Leave was then given to bring in the bill, amidst the cheers of the House.

When Mr. WAKLEY alluded to the prevention of quack medicines from going forth to the public under the sanction of Government stamps, the cheers which came from the House were heartly joined in by the MINISTERS.

CONCOURS

FOR THE ELECTION OF HOUSE-SURGEON AT THE

NORTH-LONDON HOSPITAL.

The election for house-surgeon to the North-London Hospital, has again been decided by concours, Mr. Walls, the first gentleman elected to the situation on the score of qualifications alone publicly demonstrated, having completed she term of his duties. In giving a report of the proceedings at that election (No. 23, Vol. 2, 1834-34), we stated some particulars dispersing the hospital, which is in presentative to reposit It will be sufficient to the house-surgeon to this hospital, advanted to the meat approved of the competitors for the prize; every dresserof three months' standing is eligible as a complete to the

office. The examination was n in the following manner candidites. The aniswire and under cover with motios: given in

CONCOURS AT THE

lat Deriver. The principles of treatment in surgical diseases .- Questions. 1. The relations of the femoral artery. What part of the vessel is preferable for the application of a ligature? State the reasons for its being so. What are the steps of the operation, and the cautions to be used in its performance?

2. How would you treat a simple fracture of both bones of the leg? How would you treat a compound fracture of the same hones? Describe, particularly, the position of the limb, and the mode of applying the several parts of the apparatus.

3. Describe the symptoms of retention of urine, as arising from enlarged prostate, and the treatment. What is to be expected

if the bladder be not relieved?

4. Describe the coverings of an oblique inguinal hernia, and the relative position of the vessels and the epigastric artery to the neck of the sac.

2nd Division. The performance of those operations which are likely to be required of the house-surgeon. This and the third livision were conducted in the clinical theatre before a large assemblage of stulents and practitioners. The questions, the reasons for the operations, &c., were written lown, and a number of them were put into t hat, when one was drawn by each candilate. The operations were performed by the gentlemen successively, only one canlinate being present at a time.,

1. Removal of first and second phalanges

of the finger.

2. Amputation of the finger, with a portion of the metacarpal bone.

3. Application of a ligature after amputaion below the knee. 3rd Division .- Actual application of ap-

paratus, &c. 1. Name the instruments required in am-

putation of the leg-

- 2. Show the mode of reducing luxation of the humerus, when dislocated into the axilla downwards and forwards.
- 3. What are the appearances of such disocation?

4. The application of bandages required in fracture of the clavicle.

The medical committee of the hospital binducted these examinations. The suc-penful candidate was to have been named list Monday, the signal examinations having sikes place on the previous fasturday. On Monday, however, its sun dand that two of the untillable were considered to be, in every respect, equal in the scale of merit, and it was deshied necessary that those two gentlemen should submit to a rice occe or ton. Meantime intellects of every caliber. amination by the surgical staff of the hospi- pens of all degrees of power (and why not

distinction such of the surgious putting two questions, which were the following: salm of the hand required your attention,

that it had bled considerably at the time, and a ligature was applied, and that at the end of six or eight days hemorrhage came

on, what would you do?

2. Describe the symptoms and treatment

of cedema of the glottis.

3. Describe the symptoms of dislocation of the head of the femur into the obturator foramen.

4. The symptoms of dislocation of the same bone into the ischiatic foramen.

5. What parts would you cut through, and what avoid, in the operation of tying the subclavian artery in the first part of its course?

6. Give the relations of the prostate gland, and what you divide before you come to it in the operation of lithotomy, cutting from

the perineum inwards.

After these questions had been answered by the respective candidates, the committee retired, but shortly afterwards again entered the theatre, when Dr. Thomson announced, that after the most impartial examination of the papers, and a full consideration of all the proceedings, the Committee had decided on electing Mr. Hongson, of Halifax, to the vacant office. The announcement was received with cheers. Our reporter adds, that "wishing to ascertain how far the statements were correct which are sometimes urged respecting the nervousness of candidates at public examinations, he inquired of the gentlemen who submitted their acquirements to the ordeal on the present occasion, what degree of anxiety they experienced; when he found that two of them were not at all alarmed, and that two did not experience more perturbation than they considered they might have felt, had they been subjected to the same tests in private."

CONTINUED CORRUPTION IN THE

DUBLIN COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

Siz, - The period rapidly approaches which will terminate the hopes and fears that have so long beset the several parties in the medical world, according as they are friends or focs to that expected renovation of our institutions, which is to abolish all monopolies, and introduce an order of things which is calculated to promote science, and secure the interests of the medical profession. All eyes are directed to Mr. Warburminus are in active operations we Lancier, with a liberality and a suggest general interests, beyond all praise, affords every facility to free and fair discussion. It show any symp is devottly hoped that all this may events. ate in a measure of gonnine and general pressure, where he lecture ate in a measure of gennine and general profesor, where he lectures in the reform, one which will sweep away all as ceasor, where he examines his over abuses, and enact such wholesome regula- for license (reporting to the College on tions (uniform for the three kingdoms, con- excellent and effective condition of ferring equal privileges in all) as shall entering equal privileges in all) as shall entering and asserted by where he publishes sure adequate knowledge in the practitioner, become with the results of his valuable threshold labourstioner, bonourable conduct and protection. the faction. Even of this medley crew, the expectants will, without doubt, swell the number of reformers, when they perceive same prolific establishment. which way the wind blows, and that they obstacle to the most thorough and searching reform.

The faction, too, deserve no mercy; for very teeth of repeated warnings, their conduct has been, and still is, marked with as great, if not greater depravity, than in the palmy days of rampaut toryism; jobbing and corruption are perhaps merc rife than ever; intrigue and petty party malice are still in full operation.

1. The infamous blackball still outrageously deprives the majority of the profession of their just and legal rights, Mr. Cusack's watch his Majesty's Government exclusive declaration being still unrepealed,

Lord Melbourne! frees is still transacted after the m, and to meet old objects. The College is variously and injudiciously pledged, and money is granted on the frish of decuments, garded in the readings precedents are discovered, hearted on, and sworn ta, to meet every occasion; order, deco-rum, and fairplay, which prevail in all other, even the most unlearned meetings, are here still shamefully violated and utterly disregarded. It would be invidious, and indeed difficult, to select a single instance.

6. Reform is still in the same ill odour, and as hateful a thing as ever. Never did juggling hends more fully break the word of promise to the hope, than did the concours and by law reform committees, both of which, -after giving such dreadful note of preparation, after keeping the College on the tiptoe of expectation for nearly a year. -have, alas for the instability of human hopes! departed this life, each giving birth, with all the agonizing throes of a dving mother, to a luckless report. One, mothered by a Mr. Evanson, whose celebrity has not yet I fear extended beyond a very small, but select circle of course, recommends a premium of 50% for the best essay on the concours. It is not difficult to foresee how this job will terminate, but it has the adcushioning the question for another twelve months, and throws overboard all intention, in spite of promises ad infinitum, of the concours experiment, although no less than five opportunities have already offered. The other, calved by the redoubted James Cusack, is content with recommending limits in its first (and, it is prophesied, its last) report to the College, to take no cognizance, as heretofore, of apprenticeship bargains, and also to adopt certain modifications of the half-yearly examinations; that is, the evils of both are still to be retained, for James Cusack's words are a law to a certain party in the College. Now, the examinations are notoriously a humbug, presenting an imposing aspect to the gullible public, and forcing pupils into contact with the school and its professors, to be By the suggested arrangement about aptramense revenue to James Cuerch, and perdence, quietly submits, without a public the splendid results that crown the un- land the lilegal proceeding of Mr. White.

strailered executions of the faction in the come of reform. It is to be leared, how-ever, that the impatiance of the Legisla-ture will interfere with and prevent what ten been commenced and continued under such very very favourable auspices. What

a pity! 7. The same tender regard is paid, as berotofore, to general interests and measures of general utility; never is prejudice or partiality allowed for a moment to divert the even current of calm deliberative justice. Witness the treatment of two gentlemen, both reformers, at a very recent meeting of the College. One of them moved for a committee to consider what means might be devised to render the subjects of compasative anatomy, puschased by College funds from the Zoological Gardens, more available as sources of information to the menbors of the College. By the present arrangements, all opportunity of information is confined to the curator and professors of auntomy, who also, as they purchase with College money, drive all competitors from the field. All the value the members of the College derive, consists in the few preparations that result to the museum, which could probably be purchased cheaper, if all the attending expenses be taken into consideration. This, however, being a measure of general advantage and liberal consideration, was indignantly scouted by a meeting prepared to scout anything, so that the private huxtering of Mr. Jacob continues triumphant. The other vantage, as he, poor thing, thinks, of reforming member tendered in the usual form, a notice of motion to found a chair of comparative anatomy and zoology, calculated for the members and licentiates of the College. The tendency of such a motion being to establish something of value and interest to the profession, beyond the miserable and contemptible elementary school to which the selfish cupidity of the professors confines all the exertions and funds of the College, it was forthwith anduciously ruled by Mr. Vice Sec. Harrison, and Mr. President Cholera White, illegal, and actually refused as such. A notice of motion, tendered in regular form, illegal! Such a violation of all precedent, custom, and courtesy, such an exercise of tyrannical impudence on the part of Mr. White, forms a striking contrast with the dignity, urbanity, and impartiality of Mr. Read, the late presitampered with and seduced, as has been dent. Such an outrage, even in the trish attempted before now; while, on the other College of Surgeons, - and surely no other hand, they are felt as a most tyrannical chairman would dare to not so, at least tardship and inconvenience by students. without being forthwith brought to a knowledge of his duties,-I must confess astoprintices; the whole system will continue in nished me. I shall be more astonished if full distribution; though not appearing on the the member in question, who has hitherto College tooking and will still be a source of passed for a gentleman of spirit and inde-

But there is no end to the facts that go to prove, that the innate depravity of the faction continues unattated, and that even at this, the eleventh hour, they are without a single redeeming feature in their case. Delenda est Carthago. I am, Sir, your obedient scrvant,

NEW CORPORATIONS.-MEDICAL CORONERS.

We select the following passages from the published letter of Mr. Rogerson to the New Corporations, mentioned by us last week at page 888:-

"The municipal reform bill has, either directly or indirectly, placed in your power the local administration of justice, and the election of the officers who preside over its courts. Of these, the coroner's court is one of preliminary inquiry, and, viewed in its relations to society, occupies a conspicuous

and important rank.

" Highly responsible is the execution of the trust reposed in you, and fully believing that the day is gone by, when adherence to antiquated customs prevailed over the improvements and advances of knowledge. I respectfully address you, that the coroner's court may be reformed by the application of that science, which alone can efficiently administer justice through the detection of the causes of death. The science is that of medicine."

Having reviewed the duties of the court. Mr. Rogerson says,-

" Having ascertained the first principles which govern the court, the object will be to find a class of society who can best reduce these to practice, and carry them fully into operation. Is a lawyer, whose business cramps his mind, in the study and perversion of precedents, acts of parliament, judges' versions of them, and in mechanically copying forms of law, best qualified to preside in such a court? Decidedly not,—will be the immediate answer. His professional learning and habits of life never lead him to acquire the extensive knowledge of medical science which is requisite for the execution of these duties of the coroner's court. So defective do attorney-coroners find themselves on this point, that they are in the habit of carying with them to inquests a small manuscript copy, neatly and closely written, containing a list of the most common poisons, the principal symptoms folthe appearances of the body from drowning. Mackensie.

"An objection, deceptive without the merit of plausibility, may be offered against the absolute necessity of appointing medical coroners. These inquiries, important and necessary as they must be admitted, can be obtained from a medical witness.' A coroner is present at every inquest; a medical witness sees very few of them, and at the majority of these few, the assistance of a medical practitioner is, according to the present practice, required only on account of some glaring suspicion, or strong communication, which stupidity itself could not overlook. Are the great majority of deaths on which inquests are taken, and the causes of which are unenlightened by medical witnesses, invariably unattended with suspicious circumstances? A great number of sudden deaths, requiring inquests, are suspicious, and a medical coroner, who, by the nature of his profession, is best acquainted with the causes and oppearances of death, is enabled at once to decide on the truth or falsily of these suspicious, and on the necessity of instituting a right examination by a medical witness. A coroner, with a smattering of knowledge, or with a total ignorance of medical science, with most certainly commit errors. One fact is said to be worth a thousand reasons, and among the number supporting the truth of this last position, I will offer the following, related by the late Mr. Hunt, which occurred during his confinement in Hebester jail :- A prisoner died at eleven o'ctock in the morning, and on his body an inquest was held by a non-medical coroner, under whose direction a verdict was returned of accidental death. It was afterwards proved on oath, before the Commissioners of Inquiry, that the unfortunate man was killed by a blow inflicted by one of the turnkeys, who had chained him by the neck to the wall for rioting and drunkcuness, and was irritated by his abusive language. An error so agregions as this could not occur with a medient coroner, for the view of the body required by our laws

One of the coroners for Middle goes beyond this. He carries with him are unabridged copy of "Buchas's Demettic Medicine," and supeals to it for last and correction of the amplical attnesses, on lowing their administration, and a short all description occasions. It was in constant description of dangerous wounds, and of use at the late inquest on the body of the constant description of dangerous wounds. would soon inform him of the first and directing this inquiry to the first and the first and the first and the first and first

Mr. Rogerson proceeds to argue various other questions, and thus illustrates some

of them:-

"General truths acquire additional force by the illustration of example; and the inability of non-medical Coroners to estimate the validity of evidence on, and conduct an examination relating to, scientific questions on death, is shown by the 'case of the unfortunate Eliza Fennings. It was stated that the knife, which was a steel oue, and which she had used to cut a pudding, was made black by that act, and that, therefore, the pudding contained a combination of arsenic. This, too, was asserted by a medical witness, and was the strongest evidence against her; but this combination of arsenic could not blacken steel. The Coroner knew not this chemical fact, and could not therefore discover the necessity of other and better evidence on this point, nor explain to the jury the value at which it should be estimated. The non-medical Coroner knew not the error or truth of the opinion, on the blackening of steel by this preparation of arsenic.

"In Liverpool, Mrs. . died in childbed, after an illness of eight days. Instruments bad been used to effect delivery. An inquest was held on the body, and a verdict of manslaughter was recorded against a young gentleman a medical assistant), who was publicly sent to the county jail at Laneaster, pinioned to a common felon. The evidence implicating this young gentleman consisted in statements, showing that he was present from an early period of the labour, and when instruments were used by others, that he interfered too much, which evidence was only hearsay, related to another by the suffering lady herself; and that he was seen in an ante-room with instruments in his hand, when he replied in the affirmative to one asking if he was going to use them. With this evidence, defective, presumptuous, unsatisfactory, and of secondary consequence were the Coroner and his legal officer content, and, in consequence of their incompetency from want of medical knowledge, they could Beither assist the jury, nor promote the inigation, by secertaining the nature and extent of the timberforence and the part he interfered with which were the head and from of the offense, and what was the con-sequence of dissistanterference, and what use

he made of the instruments. Highly im-

portant and absolutely necessary as these points of the investigation were, the Coroner,

strongh Ignorance of medical science, could neither question nor appreciate, though witnesses were present from whom the inquiry might have been made. Upon this evidence, defective, and miserably managed, was this young gentleman singled out as the only victim, and he appears to have been made the principal in the first degree of guilt, which was more strange and surprising than all other errors. He was subsequently discharged, on the surrender of his ball, without redress."

"I have," says Mr. Rogerson, in conclusion, "briefly and impartially pointed out the principal knowledge necessary for efficiently conducting the Court of the Coroner, which istin its nature essentially medical. The requisite legal information is soon gained by any rational individual, for the examinations seek into matters of fact bather THAN OF LAW. The Court is not one for the decision and examination of points of law, and for the award of punishment, but of preliminary investigation and inquiry on violent, sudden, and unnatural deaths, and deaths in prison, and their causes. The requisite medical information, then, must be profound, and can only be learnt by years of study and practice.

The pamphlet is published by Messrs. Longman and Co. Let the object to which it is devoted be everywhere pursued in the new corporations.

THE LANCET.

London, Saturday, March 5, 1836.

A CONDENSED report of the proceedings which took place in the House of Commons on Tuesday evening last, will be read with satisfaction by our professional brethren throughout the empire. At last the Legislature is evidently disposed to do justice to the claims of medical practitioners. As some time must elapse before the bill can go into Committee, petitions should still be forwarded in support of the measure, and we again take the opportunity of hinting to some gentlemen who have been meritoriously active in this struggle, that a petition having six signatures is just as efficaclous as one containing six hundred. Attaching seven or eight hundred names to a

notition is, colimbratively is ten application of that force which general body of the profession is once

It should be observed that the Bill which out into two parts by the wheel dia w an enactment might be under any other satisfactory description. circumstances, it would be absurd, and even The justice of the proposition for reimmischievous, to make any proposition of a bursing medical witnesses, for the devotion similar kind in a similar measure. WINESES.

repeat, is the should contempt?

imputation? That the Coroners Hill Mr. Curres passed the House of Comtions, without containing any medical clause, in the year 1883. That the Bill was introduced and read a second time without any medical clause, in 1834 That a medical clause was at length introduced in a Committee of the House, after twenty articles at least had appeared upon the subject in this Journal, and after we had succeeded in causing numerous petitions to be presented to the House on this subject, and in 1835 the Bill was introduced into Parliament with the identical clause which the Committee had sanctioned in the previous session. We have called it a "medical clause," but did even that clause provide for the payment of medical witnesses at inquests? Why, the fact is directly the reverse. Here is the section itself, printed verbatim et literation, as it was introduced into the bill of last session : -

" And whereas, at the taking of inquisitions on the bodies of persons lying dead, it is frequently necessary, for the more satisfactory explanation of the cause of the death of such persons, that a post-mortem examination of such bodies, or of some part thereof, should be made by some surgeon or other person of the medical profession, and his evidence given on such examination: and whereas there is at present no remuneration provided for such surgeon or other person, whereby great difficulty exists in procuring such post-mortem examination to be made; be it therefore enacted, that in every case where the assistance of any such surgeon for other person, for the purpose of such post-morten examination and his evidence thereon, shall be thought necessary, and be required by the coroner and jury, the constable of the parish or place in which such inquest shall be held, shall, on the direction of the coroner, pay to every such person, if he shall require it, a reathe sism of one pound), before he shall be upon to give his evidence; and such round to paid by the maid constable, shall be reimbursed to file out of the funds provided for the little of the poor of such parish; provided ships with it is to remuneration shall not be given any such paraga when he shall be called upon only to give evidence in the medical attenuant of such de-

٧.

the decrees dering his lifetime, or at the

What is to be thought of that medical writer who can be guilty of the infamy and falsehood of alleging that the enactment of such a provision as this would provide for the payment of medical witnesses at Coroners' inquests? Yet this was the clause that was introduced into the Bill of last session, - a section of the measure, be it observed, which its author then stated, and still states, was " forced upon him;" and the tame gentleman informed us in the House of Commons, on Tuesday evening last, beforc the motion for introducing the Medical Witnesses Bill was brought forward, "that he should oppose that motion," and yet. "the Member for Finsbury has behaved " shabbily towards Mr. CRIPPS, by taking the " conduct of the medical question contain-" ed in the Coroners Bill, out of his hands!"

The reader is requested to examine the stipulations of the section which we have just quoted, and then judge whether such provisions could give, or ought to give, satisfaction to the members of the medical profession. The medical witness was in no case to receive more than one pound, even if he instituted a post-mortem examination . and where the medical practitioner was summoned before the coroner as the medical attendant during the lifetime of the deceased; in other words, when he was actually called before the inquest as a medical witness, without instituting a post-mortem examination, it was expressly enjoined, in the concluding lines of the foregoing clause, that the remuneration of one pound should not be awarded to the practitioner. Yet this was the species of enactment which was to protect the interests of the general practitioner! In sooth, it is just that description of injury and insult, under the name of protection, which the SLANDERER employed by the corruptionists and bats, would be glad to see enforced against every respectable surgeon and apothecary in this country.

916

With reference to the very short Bill which is to be brought before the House, it may be necessary to remark, that from also been recommended as an external ap what the profession has lately seen of plication in some cutaneous dise the conduct of the coroners at inquests which have been held on the bodies of persons who have been supposed to die from the poisonous effects of quack medicines, it has become absolutely necessarv that the power and ascendancy of the science of medicine should be instantly acknowledged by the non-medical officers who preside in those courts. Under existing circumstances the public cannot hope for protection from any other shield or authority. If the chief officers of those courts were qualified to discharge the duties in consequence of having received an efficient medical education, then it might happen that the collateral aids of professional testimony might not be so essential in promoting the ends of justice; but it has lately been seen that in some instances the infamous quacks have either awed or seduced the coroners into the adoption of a pusillanimous course of conduct, which has had a direct tendency to perpetuate the pestilence which is now so rapidly selecting its victims from the ranks of all classes of society. The It was one of loss of power in the lower exjuries, however, acting upon the sturdy principles of common sense, have faithfully and nobly discharged their duty to the com- constitution was good, and the excretions munity, and we doubt not, on the next occasion, when an inquest is held on one of function not being sufficient to admit of dethe poisoned, that the chief culprit will be made to suffer, at one blow, both for his boundless avarice and his numerous crimes.

CORONERS INQUERTS

PURGATIVE SEEDS.—At the last meeting barts was at a loss what name to give to the of the Medico-Butanical Society, Dr. Sto-disease, whites that of "debility," or what more made some remarks on the seeds of to presented; but acting on what he was the satrophe cureas, samples of which, in sidered to be the safest plan, he of their capsules, had been sent to the Society half a grain of the sulphase of iren

il acts in a similar way, and two oit licrosse its pargative effect. It has ticularly in itch and berpetic cruptle also in common rhoumatism, and taken internally, it has been found beneficial in dropsy, apoplexy, and obstinate constipation. Some experiments made by ORFILA to prove the poisonous effects of the seeds were detailed. The effects seem to depend on the violent inflammation produced, and the sympathetic action of the nervous systom. The poisonous effects are more strongly marked when it is introduced into the stomuch than when applied to the cellular tissue. It was supposed CAVENTON who performed some experiments on these seeds, that the oil obtained from them was in every way, similar to the croton oil imported from Incha. The properties of the two oils are, however, very distinct, though their medicinal effects may, in general respects, agree. Dr. SIGMOND thought it possible that the seeds of the satropha curcas and the croton tiglium were both employed in the preparation of the croton oil, and that this fact might account in some measure for the great variation in strength of that medicinal agent.

ACCUMULATIONS IN THE COLON?-At the London Medical Society, on Monday night last, Mr. ROBARTS detailed a case which he judged worthy of attention, because similar cases had not been recorded. tremities, but not amounting to perfect paralysis. The patient, a coachman, sixty-seven years of age, had lived a regular life, his and secretions were well performed, at least apparently so, the derangement of any tection. In the calves of the legs there was, for some days, great pain, increased by exertion, but not by pressure; and this pain was followed by a numbress, which was not always constant. His rest was greatly disturbed, and any attempt at walking, after & few paces were accomplished, was followed by total inability to mave further. Mr. Rotheir capsules, had been sent to the Society by Mr. MONTGOMERY MARTIN. These saightly constead and fresh, after being saightly rearested, and infused in spiced wine in doses of two or three, act as gently first in the spice of two or three, act as gently first in the spice of two or three, act as gently first in the strong pureatives, and in still larger doser they are strong pureatives, and in still larger they are actively poisonous. The R. hallevad would have tell the plant of the spice of three weeks the man was completely well. An opposite treating Mr. larger they are actively poisonous. The R believed, would have led to a complete

CONDON HOSPITAL.

paralysis of the limbs.—Mr. Meator luding to the case, considered the tion in the nervous course pendent on an accumulation in the cold from chronic inflammation, in which state; tion chroate semantation, in senter was although said of second of the season of the s cinc prescribed, he thought, justified this view. Mr. Robaurs strongly objected to this supposition. A loaded state of the colon would have been directly manifested had it existed. Moreover, no increased discharge from the bowels, either before or after he was consulted, had occurred .-Mr. Moone related the case of a lady who had experienced excessive cramps in the legs, and who had taken mercurials and other medicines, aperients, &c.. without benefit, and who, on going into the country, and falling under the hands of a physician who had kept an eye on the state of the colon in particular, was ordered three grains of the sulphate of iron, with one drachm of the carbonate of magnesia, twice a day, when large quantities of scybalze were dislodged, and the cramps and other symptoms immediately abated, the lady fully recovering.—Mr. BRYAKT, in the course of the evening, remarked, that he had invariably found, in post-mortem inspections, a ramollissement of the spinal marrow to be the consequence of idiopathic paraplegia.

The Society's Anniversary Dinner is fixed for the 8th of March, when Dr. Blicke will deliver the oration.

MR. OSBORN'S EXPERIMENT ON PLOOD.

To the Editor. - Sir: Allow me to express my surprise at the manner in which "W. ('., of Brompton-square," has criticised my statement on the detection of tar in the blood. Had he repeated the experiment, he would have been able to form a much more correct opinion of the process as well as of the substance obtained. Of chemistry, W.C. bimself, notwithstanding his strictures, apsears to be very ignorant, or he would have known from experience, that in all chemical species, when a strong heat is required, it is necessary to use a metallic or an earthen-ware retors, and not glass. I beg to inform that I was not analyzing the bland, as aspears to have supposed, but expeririting to the figit, and consequently had a different objects, view. "W. C." appears what ious to have we had to the content of the content o he evaporation and reptrit. Why, on the urface of the their of course. With reard to the chalk, which he thinks I was too liberal with he could not possibly have size of the end of the thumb, it was removed

and the street of

the quantity required. I am well that I was more than was sufficient to decompose the acid, and should I ever resease the experiment, I should rather in-crease than diminish the quantity, which I know, from experience, it is necessary to do. I am sorry that "W.C." has wasted his time in attempting to decide on what he evidently does not understand. And as he has been so bold as to assert that my experiment was not based on a scientific principle, perhaps, after he has taken the trouble (if he be able to perform the experiment and investigate the result), he will have the goodness to state it briefly to the public, and add his name to the account. I remain, Sir, your most obedient servant.

HENRY OSBORN, Southampton, Feb. 29, 1836.

PREJUDICE VERSUS SCIENCE.

To the Editor .- Sir: The medical profession have universally expressed their surprise that Drs. Ritchie and Webster should not have been admitted as candidates for Professorships in King's College, Strand, in consequence of their being Dissenters. may be interesting to many of your numerous readers to know that this exclusive spirit had its wicked operation on a former memorable occasion. Mr. KEIRNAN, whose anatomical and pathological knowledge eapecially qualified him to fill the pathological chair in any University, was rejected by the Council of King's College, on the plea of his being a Dissenter ! A beautiful collection of Mr. Keirnan's preparations of the liver was presented by him to the museum of the King's College, but even these unique specimens of art and science had no influence on the bigots. I am, Sir, your sincere admirer, and humble servant,

A LATE PUPIL OF THE COLLEGE.

NORTH-LONDON HOSPITAL.

ORTEO-BARCOMA OF THE JAW .- REMOVAL OF THE SUPERIOR MAXILLARY AND MALAR BONES.

ANN STRUTHER, aged 21, was admitted, February 24, under the care of Mr. LISTON. About four years ago she was very much annoyed with pain in the left side of the head and face, attended occasionally with swelling, which symptoms at the time were attributed to cold. Pain in the teeth of the left superior maxilla supervened, and a tamour appeared on the outer surface of the gum. Three teeth were extracted, with the hope of giving relief, but the swelling afterwards rapidly increased. When about the

and continued the process of the manufacture of the second of the second

After removing the central incisor of the right side, the surgeon commenced an incision a little below the inner angle of the eye, and carried it obliquely under the corresponding aid of the nose, so as to detach its cartilage from the bone, then through the lip, into the mouth, in the mesial line. He next made an incision from the prominence of the check to the angle of the lin. The flap thus formed was then reflected upwards. The tumour was now so far exposed as to be ascertained to extend considerably backwards, and the operator found it necessary to make another incision in the line of the zygomatic arch, so as so fall nearly at right angles on the outer perpendicular one; this exposed the whole extent of the tumour. With the well-adapted forceps introduced by Mr. Liston, the nasal process of the superior maxilla was divided. The operator next cut through the zygomasic arch, near the suricle, and then ough the malar bone, at the transverse facial spture, into the spheno-maxillary wore; the diseased maxilla was separated with great facility from its fellow of the opposite side, by strong scissors, leaving the palate entire, and untouched. The diseased mass was now readily removed, involving the whole of the superior maxillary bone, and the whole of the malar. A large artery, which was bleeding very freely probably

antho;

Mr. Lixton pretrued using the forceps in this case, as he thought the employment of the saw, or the mallet and chief, would have jurisd the party, and here predactive of such more differing to the patient. The operation might have been as quickly perferring with those instruments as with the forcers.

-March 2. The patient hidding encountingly with a the answer water ratioval on Monday.

This operation is worshy of record, both from the lacility and the celerity with which it was performed. The case atogether possesses much interest for medical men, and any gentleman who wishes to inspect it will find every facility afforded him for that purpose, should he pay a visit to the hospital.

PROBLASIS.

William Snook, etat. 22, a footman in a gentleman's family, admitted December 30, 1835, under the care of Dr. ELLIOTRON. He has, until within the last six or eight months, enjoyed good health, when (May he became slightly indisposed, and there appeared a reduces of the skin, affecting the thighs and posterior portion of the knee joints, filling up the popliteal spaces. This continued for two or three days, when a seniness was first perceived, to which there was quickly superadded painful fissures or rhugades, from which a serous fluid of an aerid nature was continually exhaled.

He was treated for some time by a general practitioner, who prescribed the decoral practition of ducamara and blue pill twice a day. Copious ptyalism was by this means induced, but the disease nevertheless increased in severity, and about a fortught or three weeks since he gradually lost all sensation and motion in the inferior extremities, and perceived some numbroes in the arms and hauds, without, however, affecting volition. Speech became affected, and he hesitate considerably; the month being also drained unwards and to the let side. There a printers, however, gradually distincted to verify up to the period of his admission the hospital.

At the present verification of the present of the p

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications to Mr. WARLEY may be addressed to him at his residence, 35, Ban-FORD SQUARE.

MR. FERRALL.-With reference to those concluding remarks of "OBSERVATOR" in his communication in THE LANCET of Feb. 20th, which relate to Mr. Ferrall, we feel bound to my that their tendency escaped our notice. In our previous number we did not merely state that, " the suttenticity of the petition from the Sisters of Charity " had been denied," as the impression on our mind was, that no such netition had been presented of all. We are now authorized to say that se petition was presented on behalf of Mr. Ferrall from that or any other quarter, and that his only communication with Government on the subject, was his own letter to the Chief Secretary, stating his baving filled the effice of house-surgeon. to the Richmond Hospital for nearly five years, &c.; and this communication was ed to enlarge very rapidly. The age the would by a member of the Government, To the Editor. - Sirty The cas direct system which has hitherte ! valuable journal in the highest est the "liberal world," assures me this letter will be published. The last number of Tax LANCET contained a paragraph stating it to he Dr. Cummin's intention to resign his chair in this school "in deserence to the exasperated feelings of the students, " which I can faithfully assert was read with surprise and indignation by every one of them, and considered to be equally malicious as false, on the part of the correspondent. Such rumour has not existed, the pupils being satisfied that Dr. C. had no particination in the scurrilous and prejudiced account of the meeting at the Crown-and-Anchor, given in the Medical Gazette. am, Sir, with every respect,

A SENIOR STUBERT IN THE ALDERSGATE MEDICAL SCHOOL. . Reading-room, March 2nd, 1836.

To the Editor .- Sir: Between the period of Mr. Smith's rejection and the meeting at the Crown-and-Anchor, I had occasion to call on Dr. Cummiu, at his lodgings. The conversation turned on this point, and Dr. C. mentioned that he knew Mr. Smith, and that he considered him to be a clever and well-informed young man. Of course, Sir, it is impossible that Dr. C. should have any connection with the "Gazette," for I hope that no one who is a member of our profession could allow another to remain under the stigma of ignorance, when he knew or believed to the contrary, and had so ready a means of stating his knowledge of that fact in print. Your obedient servant, March 1st.

Mr. W. F. SHORBRIDGE has addressed a letter to us in which he states that the late protest from Guy's Hospital in favour of the Apothecaries' Hall, was not "a hole-andcorner affair, being done in the face of every one belonging to the hospital." He says that " Messrs. Mugg and Bent" (Mr. Mugg's name was misprinted Muggand in a late LANCET) " could not, either with or without favour at court, have passed the Hall, because the former is not out of his apprenticeship, and the latter did not attend the hospital until last year." Our correspondent adds, "that Messre. M. and B. did not induce the junior pupils to sign the protest." The "fact" which Mr. S. quotes respecting the Crown-and-Anchor meeting is certainly not a "fact." We would readily have given insertion to the whole of our

by Dr. W. Cummin. Mr. Lank having "the assertions of three of interioral in a second so extensively circulated as Tas Lancer 7 Me. Lush has overlooked the fact that these essertions were not "contradicted" on analyzage anthority, but on the expressly declare statements of the gentleman whose declara-tions were first of all impugned. To him we beg leave to refer our correspondent, Mr. Lush has also suffered the fact descape his memory, that Dr. W. Cummin is charged with getting his bread by editing an anonymous periodical, whose peculiar claim on its subscribers is founded on its unceasing attempts to destroy the moral character of an avowed writer, by statements which are notoriously false, - a crime which in iniquity and turpitude it would be difficult to surpass.

A copy of the depositions which were taken at the inquest that was held on the body of Captain MACKENZIE is before us, but these are by far too voluminous for insertion in their present form. A condensed abstract of them, however, is in progress for publication. The prosecution of SALMON is not to be conducted by the parish. The prosecutors, therefore, will be entitled to the gratitude of the entire medical body. The depositions contain many statements of a very interesting character. The disclosure which took place at this inquiry, is a compound of impudence, folly, and infamy, almost without a parallel in the annals of quackery.

Some resolutions having been forwarded to us relative to the contents of a note which appeared in the last LANCET headed " Gower-street," we may observe that it has since been explained that it was indited uuder an erroneous impression, and that the services of no teacher can be more highly valued than are those of the gentleman whose absence from the usual scene of bis duties was made the subject of comment. It could not have been known to the writers of the note in question, that most of the hours which are spent out of the dissectingroom, are devoted to a practical examination of the more advanced students,-not an examination consisting of the rote questions of our books, but founded upon s thoroughly scientific acquaintance with the structure of the human body.

Letters from Mr. Denham, R. B. L., Mr. L. (uf T.), An Assistant Chemist, J. B .- The letter of a M.R.C.S, will probably appear

C. The second, also, of the two have given insertion to the whole of our correspondent's letter, had we not been enabled in this brief space to present a statement of all the facts which he avouches.

Mr. John A. Lush, of the Aldersgatestreet School, assures us that the feelings of the students of that school "have not been all we are satisfied on this points."

THE LANCET.

LECTURES

ISEASES OF THE BRAIN AND NERVOUS SYSTEM.

W IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL,

sysician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculte de Médecine of Paris.

LECTURE XV.

RAMOLLISSEMENT OF THE NERVOUS CENTRES.

(Continued from p. 891.)

Ramollissement with Contraction of Limbs.

motion produced by ramollissement of M. Rostan on softening of the brain. ie brain, we have mentioned contraction so deal of energy and reason on its value is a pathognomonic sign. There is a good all of traits its this; contraction is a pathognomonic sign. There is a good all of traits its this; contraction is a pathognomon when it occurs in an early past but we was allow, on the other that the same classes do exist where this when once established, this contraction does not always exist in a permanent manner; it is not unusual to see it disappear crictly taggether. I finded in our the dancer of comments and the same cricking the same cric ion, will tell you, that if cases of ramollis- recover their power of motion, or, what is

sement without contraction have been observed, it is because the cases were not studied with sufficient attention or minuteness; the observations imperfectly or carelessly reported? This may he true for a certain number of cases, because when an appeal is made against accuracy and fidelity, one can only answer for his own observations; but we can affirm, that we have seen individuals in whom ramollissement was announced from the very commencement of the symptoms, by paralysis alone, without any contraction of the limbs or muscles: of this we are perfectly sure. The nature of the disease was determined after death by inspection of the body, and during life the functional derangements were noted down with accuracy and care. If such a symptom as contraction existed at any period of the malady, it could not have escaped our notice, especially as we looked for it in all the cases of ramollissement that fell under our own observation. You will find several cases demonstrating the truth of what we have just advanced, in the fifth volume of As one of the most frequent modifications the Clinique Medicale, and in the work of

However, whenever contraction does exone or more limbs or muscles; this con-list, we may diagnosticate the presence of action consists in a flexion of the limb, ramolissement with great probability of ined to rigidity, and presents the same being right in our judgment, for, although flerences as paralysis, with respect to its the absence of this symptom, as we have igree, mode of appearance, march, and just said, does not prove the absence of at. When developed in the commence-softening, yet its presence is a very strong ent of the disease, contraction is an expression in the dient symptom; indeed, one of the best brain. Like paralysis, the contraction may gns by which we may diagnosticate ramol- come on in a gradual manner, and increase sement. It certainly does frequently exist slowly, until it terminates in loss of motion, a symptom of the disease in question, which latter continues until the end of the ad M. LALLEMAND has insisted with a disease. When it persists for a length of and deal of energy and reason on its value time, the force with which the muscles are

No. 654.

more common, they remain feels and benumbed, or more or less paralyzed. Again, we may have cases where the contraction disappears altogether, and is replaced by paralysis, or where these two phenomena alternately assume each the place of the other, as we have already seen paralysis and convulsions alternately attacking the affected limb.

The contraction may appear in a sudden manner; in fact, swyral cases of ramellissement have commenced by a violent contraction of one or both limbs on one side of the body, and then the symptom becomes peculiarly characteristic of the disease.

Paralysis, direct, and opposite the Lesion.

The progress of the contraction also varies in different cases; sometimes it persists, either gradually increasing, diminishing. or resting stationary; in other cases it may remain only for a few hours, or even minutes, and then be replaced by paralysis; and, once gone, it may either never appear again, or return only at uncertain intervals. We have ourselves witnessed all the different lesions of motion now described; you see that they are numerous; but this is not all; these diversified symptoms may also vary according to the different seats which they occupy; in some cases only a single limb is affected; in others the two limbs on the same side of the body are contracted. Finally, in a certain number of cases, the contraction affects the four limbs at the same time; these different lesions seem to depend on the different seats of ramollissement in the nervous centres; and here an interesting question presents itself,-Do we observe a diversity of symptoms, according as the ranollissement may occupy the anterior portion of the brain, its middle portion, or the posterior lobes? Does softening of the striated bodies manifest itself by peculiar phenomena, which enable us to distinguish it from softening of the thalami, or of any other part of the brain? This is exactly the same question which we took such pains to resolve when treating of cerebral hemorrhage. It is to be answered in the same manner, and we must refer you to what was said upon that occasion; it were useless to repeat now what has been already said. The paralysis which results as an effect of ramollissement of the neryour centres, generally affects that side of the body which is opposite the injured hemisphere of the brain; this, if you re-member, is the same law which governs the less of motion in cases of apoplexy, where the paralysis is almost universally crossed; however, we find some exceptions to this rule; the paralysis is sometimes direct and not opposite; in some cases ramollissement of the brain, as well as cerebral hemorrhage, gives rise to loss of motion on the same side

of cases which we analyzed in a with the object of determindisease of the large is direct or opposite; the two last cooce, taken from the thesis of M. CHAMBEYRON, were cases of ramplissement of the brain, and not of hemorriage. The intensity with which the contraction manifests itself is various, and it may occupy more or less of the four members at the same time. In some cases we see the muscular contraction confined of a length of time to a single ringer, or even to a single phalanx of that finger; sometimes it extends to all the fingers of one hand, or to contraction of the fingers we find joined a flexion, more or less permanent, of the fore-arm or the arm; the same remark is applicable to contraction of the lower ex-tremity; one or more that may be flexed, or the leg forcibly bent upon the thigh.

Ramollissement with Convulsions.

The different forms of lesion affecting motility now described, may present themselves with different degrees of frequency; however, they belong peculiarly to ramollissement of the nervous centres, and when we observe them in any case, we may diagnosticate that affection with a great certainty of being right.

It is unnecessary, however, to warn you that ramollissement of the brain may be accompanied by certain accidents which are not comprehended under the rules now laid down, and if you were to meet them in practice, you would in all probability be led astray unless acquainted beforehand with these, as it were, anomalous phenomena. Thus some patients are affected with general or partial convulsions, very similar to those we observe in cases of cerebral congestion or meningitis; when partial, they affect the side . of the body opposite the softened hemisphere; general convulsions are almost always the effect of a double lesion in the brain. Finally, in a few rare and exceptional cases, the convulsions have been seen to attack the same side of the body as the lesion in the brain.

Ramollissement producing P.pilepsy and Tetanus.

Ramollissement of the cerebral hemispheres may sometimes declare itself under the appearance of epilepsy. M. Letter has published an observation of this kind in the Journal Hebblanadaire, February 1830; the patient, who had gone to bed in good health, was seized in the night with violant oplication fits, and soon died; an extrastve reliasement was found to the superficial and deep-arated that of one hemisphere.

of the brain, as well as cerebral homorrhage, dgirn, in some cases randitionment progives rise to loss of motion on the same side duos symptoms of tetanus, either partial or of the body as the ramellissement. Thus, in general, but these cases are exceptional.

cases we find mention made being the only lesion of this also is an except llissement without an eating Mostity.

Here are cases where the lesion of mollity is unusual, and different from those which commonly attend ramollissement of he nervous centres; in some cases all sympoms of this kind are absent; we observe seither convulsion, nor paralysis, nor conraction; in a word, the patient exhibits no ymptom of injured modility. This is the ame thing as we occasionally observe with espect to the intelligence, but it is infinitely nore rare; the exception, however, does exst. We have seen examples ourselves, and he observations published by other authors grove beyond doubt that ramollissement of he brain may terminate fatally, without saving once produced the least modification if motion. These cases are generally seen in iersons wasted away by long ill-health, re-

Lexions of Sensibility

constitute a set of symptoms of some im-jother cause. portance in the diagnosis of ramollissement of the cerebral hemispheres. These lesions in relation to the constancy with which it may have their seat, either in the brain it self, or in some other part of the body.

The first and most remarkable phenomenon to which we would direct your attention, is the headache that accommunics a! great number of cases of ramollissement. This symptom, noticed by all writers on cerebral ramollissement, and on which M. ROSTAN insists with considerable force as a sign of the disease in question, is seen in a majority of cases, although we have witache was completely absent. This modification of the sensibility, produced by softening of the brain, has not always the same In some cases the headache is exseat. In some cases the head which terrors, and the symptom is also valued by instead the point of the head which the commencement of the malady, continues. The pattern, the seat of the disease. The commencement of the malady, continues the pattern, the seat of the disease with death. In other cases the leadache disappears in proportion as particularly the septial seat of the malady continues.

and the seat of the ramollissement in the substance of the brain; other patients comlain of a vague pain, occupying indistinctly the whole cranium, and which they are enable to localize, otherwise than by saying they have a headache. In other cases, again, the pain is fixed, circumscribed to a small part of the head; but this does not correspond, as in the first set of cases mentioned, with the lesion in the brain; on the contrary, it is situated at a greater or less distance from the softened point. Thus the pain may be confined entirely to the forehead, although the ramollissement is seated in the posterior lobes of the cerebrum, or even in the cerebellum. There are cases where the pain, general and vague in the first instance, becomes limited as the disease advances. Finally, we sometimes see the pain diverging, as it were, from a central point, attacking other parts of the head, and extending even to the neck or thoracic extremities.

The intensity of this headache is very variluced and worn down by some chronic distable; in some cases the cephalalgia is exase, for example, and the ramollissement cessively intense, and the patient complains isually occupies a small portion of the of a lancinating pain which often forces him acreams substance. But we must again to scream out from excess of suffering. In open that they are rare. The number of other cases the cephalalgia is much more uses of ramollissement now published is feeble; the patient, perhaps, complains of a treat, very great; perhaps we could collect weight, of an unpleasant sensation, either etween two and three hundred cases scat- confined to one point, or extending to the tered through different works, yet we only whole cranium; or the headache is so alight, know of six or seven cases in which no that unless you ask the patient directly lesion of motility has been observed. This whether he suffers in the head, this sympis all we have to say in respect of the lesions tom may escape your notice altogether. We of motility which a company ramollissement do not find that it has any peculiar distinof the cerebral hemispheres. We shall next guishing character: in some cases the paspeak of lesions of sensibility as symptoms of tient describes it as laneinating; in others ramollissement of the cerebral hemispheres, as a dull and heavy pain; in a word, we find here the same varieties as to character, as we observe in headache arising from any

> This modification of sensibility varies also may exist. In several cases the patient complains of his head throughout the whole course of the disease; his headache is con-stant, and never quits him. In other cases the pain, habitually slight, is much aggravated at certain intervals, is renewed under the influence of moral emotions, by febrile reaction, exercise, &c., or we find that the headache returns without our being able to explain the cause of relapse. We call to mind one case in particular, of a curious nature, where the cephalalgia was completely intermittent, and returned at certain fixed periods, and the disease was mistaken for one of intermitting neuralgia.

The duration of this symptom is also va-

according to the period of time at which it commences, thus it may optio the acene, and constitute the first symptom of ramollistement, or it may precede all the other the state of phenomena, and exist solely in an isolated much more tries the cranitation of cumuner, for a great or less naried before the manner, for a great or less period before the tankous sensibility extends lively to the actual development of the lesion; the dura- whole integuments of the body, and who tion of this prodrame is generally not long; least contact becomes insupportable. The symptoms connected you prick the skin, he does not feel the with the organs of sense do not aford any slightest pain, &c. In the third series, the thing very particularly worthy of mention; sensibility, far from being diminished, is, on or all that we might say would be merely a concition of what has been already ex-The diminution or complete abolition of plained under the head of hemorrhage; the sensibility, is chiefly remarked in the inte- sight may be either diminished or completely lost; the hearing may undergo the same time the seat of a lesion of motility. In modifications. In one case, recorded in our Clinique, the patient lost the pover of seeuntil paralysis has already existed, but in ing, on the same side as the paralyzed limb.

Lesions of the Digestion, the Circulation, and the Respiration.

Let us now pass to the influence of ramollissement of the cerebral hemispheres on the various acts of nutritive life; here also we have very little to say of importance. The digestion is but slightly, if at all, troubled; the tongue remains natural, and the abdomen is not painful or tunid; however, in a few cases, we may observe vomitcostive: these, as you see, do not constitute does not seem to suffer any great degree

The requiration becomes impliore frequently the sculties or circulation ains intact. When the ra-:spiration: colliseement is formed in a slow and gradual mmer, this faculty is not deranged at first i any degree that attracts attention; howver, as the disease advances, the functions f the lungs become impeded, then embarused and difficult, and the patient at length ies & a kind of asphyxia. If the ramolssement progress very rapidly, -- be formed a sudden and violeat manner, - the respiition at once becomes embarrassed.assumes se stertorous character, and it is a matter the greatest difficulty to distinguish this rain : indeed, under certain circumstances, is actually impossible to say whether a itient suddenly seized with coma and steret is certain; we have witnessed it more the cerebral substance? can once, and your future experience will o doubt attest its truth.

Rumallissement Acute.

sions of intelligence which we have al ady described at sufficient length.

The secont sim resembles the first in the diden annihilation of the intellectual faculty, but lesses the samples affecting one more limit to have contraction; and this latter sign went indicates almost in a certain manner that the disorder is a ramellissement of the cerebral pulp.

In the third form also we observe a sud-

den loss of consciousness; but the lesion of mothity is neither manifested in paralysis or contraction; we have convulsions: these affect either one side of the body or both. When the convulsions are confined to one half of the body, we may diagnosticate the presence of ramollissement; but when they are general, affecting various muscles on both sides, it is not so easy to discover the real nature of the lesion on which they depend.

In the funrth form we do not observe any sudden loss of consciousness: the intellectual faculties remain intact, but the power of motion is either suddenly lost, or modified in various ways already alluded to. These rin of the disease from bemorrhage of the cases are also embarrassing, and require cautious examination. They may be very readily confounded with hemorrhage of the brain, for what is more natural, when you rous respiration be not affected with apo- find a patient suddenly deprived of all exy, though after death we find nothing power over his hand or leg, than to attriit settening of the nervous pulp. This bute this lesion to the effects of effusion into

Ramollissement Chronic.

We now arrive at a fifth form, in which ramollissement appears as a chronic disease; We have now passed in review the differ- here the intellect is preserved for a long it symptoms which accompany rannellisse- period of the disease, and we do not observe out of the cerebral hemispheres; but these any sudden modification of sensibility or nctional derangements do not always motility; the disease, on the contrary, roup themselves together in the same marches gradually, the patient at first finds samer: hence arise different forms of the that the limbs at one side of the body are a me disease, with which we must be ac- little weaker than those at the opposite minted, whose features we must study, side; sometimes they are only a little pain-herwise our history of ramollissement ful, but this feebleness gradually changes ould remain imperfect and unfaithful. In into true paralysis, or contraction: these se first form to which we would direct your symptoms persist, or become more and more tention, ramollissement commences and intense; the lesion of the brain now exerarches with all the characters of an acute cises an influence on the conomy at large, sease; there is a sudden loss of conscious-ess, accompanied by paralysis of the mus-es on one side of the body; this case is physicial, or worn out by suffering and are. Ramollissement of the cerebral he- general weakness. Cases of this kind are ispheres very seldom commences with much more easy to diagnosticate than those ich violent symptoms, but we have seen in wnich the disease commences brusquely, camples of this kind, and we were inti-and imitates apoplexy. When we find a artely convinced that the patient laboured patient enjoying the full exercise of his in-uler an attack of anoplexy. We opened tellectual faculties, but in whom the power e body after death, and sought in vain for of motion in one side of the body has been e expected compliant, on the contrary, we gradually lost, or where the hand and arm and an extensive softening, without offur have become slowly contracted, we may with on in one of the hemispheres. The loss some degree of certainty pronounce on the conscionsness, marking the access of this existence of ramollissement, for there is rm, may persist until death, or the come only one other lesion, viz. tubercles, which sappears, but leaves behind it the various can imitate this form, and even they perhaps produce their symptoms more by the state of the cerebral pulp round them than from anything else. Thus, if in some cases the diagnosis of ramollissement be easy, there are others where we find much difficulty in distinguishing it from cerebral hemorrhage, from meningitis, or from accidental products in the brain.

Finally, in the sixth and last form that we shall notice, the disease is completely latent. During life the patient does not exhibit any single modification of the intellilatent. gence, of the motile power, or of the sensibility, yet after death we find softening of one or more points of the cerebral hemispheres, sometimes existing to a very considerable extent, from the insidious manner in which it marches, and from the complete absence of all symptoms; this form justly merits the name we have given it of "latent ramollissement."

I have now given you a pretty extensive description of the symptoms that accompany ramollissement of the cerebral hemispheres; but I have still a few words to add upon this part of our subject, after which I shall pass to ramollissement of other portions of the nervous centres. The observaupon a certain number of forms late which ramollissement of the cerebral hemispheres may be distinguished, according to the different symptoms which attend and characterize each particular form. I have enumerated six species of raniollissement, founded on the absence or presence of coma, of paralysis, or of convulsive movements. The last form which I named was the lateat. from the fact of its being announced by no functional lesion whatever, by none of those symptoms which in all the rest lead us to establish the existence of rannollissement of the brain. We also saw how ramollissement of the hemispheres may sometimes present itself under characters so well marked, so prominent and decisive, that we cannot possibly confound it with any other lesion. In some cases, however, we have seen the symptoms of such a nature as to bear a strong analogy to those resulting from cerehral congestion, or even hemorrhage of the brain, while it requires some caution and experience to distinguish a third series from inflammation of the cerebral membranes. We now return to the history of those functional phenomena which manifest themselves during the course of ramallissement of the cerebral hemispheres. A few observations in addition to what we have already said, will complete what we have to say upon the subject.

Order of Succession of the Symptoms of Ramollissement.

The symptoms of softening of the brain do not always present themselves to our notice in the same order of succession, or spheres is preceded by a prodrome; this is has been superadded, or coexists with th generally a headache, more or less intense, softening of the cerebral substance, and w

which we spoke in a former mis the ais cephalelgia frequently precides an the ther phenomena, all other lesions of motility of sensibility it is then a premofilibry symptom, or airodrome, but it does not possess any character by which we can distinguish it from the headache that precedes apoplexy and various other disorders of the nervous centres. In a greater number of cases, the headache commences with the commencement of the disease itself, of which it then constitutes an integral symptom. In some cases we have no cephalalgia, but the ramollissement is preceded by the different accidents (already described in their place) which characterize cerebrat conget on. Finally, we may observe some cases after up uremonitory symptom exists; the patient is suddenly seized with paralysis, contraction, beadache, delirium, or other lesions of sensibility, motility, or intelligence.

Whatever may be the form under which ramollissement of the cerebral hemispheres presents itself, either with a producine, or suddenly and under an apoplectic form, its duration varies under various circumstances. It is not an easy matter to determine in all cases the exact length of the disease, for we cannot always say at what precise time it has commenced. In some cases, however, the task is more easy, the sudden development of the disease and its rapid course remove all doubts as to its duration. In some of these latter cases, the disease ends fatally in a very short period of time; its march is most rapid, and the individual has ceased to live a few hours after the first symmetoms of rangellissement have manifested themselves; other cases, again, terminate still more rapidly. The progress which the disease makes is as rapid as that observed in the most violent forms of cerebral apoplexy. After having lain for one or two hours in a state of paralysis, or complete coma, the patient, who before that period seemed to enjoy perfect health, dies. These examples of ramollissement, destroying in one or two hours, are, however, very rare indeed. In a majority of cases the disease continues for a longer period, and does not terminate fatally before a lapse of ten, twelve, or twenty-four hours, and still more frequently is protracted to so many number of days. In other cases, again, ramollissement assumes the character of a chronic malady; we count its duration. not by hours or days, but by weeks. Thus you will find cases on record where, this associated in the same group; hence arise, lesion continues for thirty, as forty diversity of the same anatomical lesion, various symptomatic forms that we should be acsumption to the same manufactor of the same manufactor of the same manuer or with identical phenomens:

in some cases ramollissement of the hemiin some ca

may expect to find an acciden developed in the brain,

of the care in hemspheres is almost con-stantly fatal. Indeed, it is not easy to find even a single case in which we can say with certainty that any other result took place; however, we must notice the opinion of some authors whose prognosis is more favourable. Thus M. LALLEMAND quotes a certain number of cures. In his treatise on diseases of the brain and its dependencies, you will find it laid down, that a certain number of cases of ranfollissement terminate by induration of the cerebral substance: he thinks ramollissement may be converted into the opposite andition of hardening, and that a cure may finally take place in that manner. This is a fact which certainly requires confirmation. When we consider that the symptoms which characterize ramollissement of the brain are so various and uncertain, when we reflect that they may and have often assumed such a form, that it is impossible to distinguish them from meningitis or cerebral apoplexy, we cannot, in the actual state of the science, permit our-that a case of direct p selves to conclude with M LALLEMAND, served by M. JOBERT. that a circumscribed induration of one of the hemispheres demonstrates sometimes the existence of previous ramollissement.

A word on the manner in which death takes place in this disease. The fatal termination may simply be the result of functional derangement of the brain produced by ramollissement affecting any one part of its substance. In some cases it requires but a lesion of a small point to determine so great a disturbance of the nervous system as to compromise existence. In other cases the dies in a state of general prostration.

. In addition to the one case which M. ANDRAL gave in a late lecture, in which paralysis existed on the same side of the body as the lesion in the brain, we take the liberty of directing attention to the following cases presenting instances of direct paralysis, To they carried wafford every guarantee of authorsticity :-

there is a case, detailed by M. BAYLE, of chronic inflammation of the membranes ever the left hemist here, producing paraly-

The same mempir contains an account of seven other observations, extracted by M. BAYLE from different authors, but they do not all present the desirable degree of accu-

There is a case of encephaloid tumour in the right bemisphere, in a child twelve years of age, who had epilepsy, and paralysis of the right side, communicated to the "Anatomical Society," and noticed in its bulletin, Arch. Generales, 1834, April, p. 602.

A case of pearly tumour situated over the left peduncle of the cerebellum, producing paralysis on the same side as the lesion, was read before the same "Anatomical Society," and noticed to the Arch. Generales, 1834, March, p. 415.

Finally, two cases were published by M. DECHAMBRE, interne at the Salpetriere, of which an analysis will be found in the Rerne Medicale for October, 1835, p. 80.

In the Archives Generales for June, 1834, p. 239, &c., M. DENONVILLIERS mentions that a case of direct paralysis had been ob-

ON THE EXISTENCE OF

NERVOUS INDUCTION

IN FUNCTIONAL PROCESSES.

By W. F. Bow, M.D., Aluwick.

Or, suppossions. The spinal accessory is a motor ing the stomach to contain some sub-tance, nerve; that is, it carries an influence then, when the muscles of that organ con es, of the par vagum, which carry the in- through the cardiac orifice. fluence of this nerve, are motor nerves. The contractile nerves of the arteries of the spinal nerves are sentient and motive. the stomach during digestion, assume, also, thought it proper to distinguish the nerves

Ly calling them motor and motire. Were it not for the law of nervous induction, the act of filling the stomach with food of the gastric fluid. Digestion could not would be attended, at all times, with a sen- proceed, were the activity of the par vaguu sation of pain rather than of pleasure; for not, partly, supported by nervous influence the muscular fibres of the wsophagus, whose office is merely to transmit the food, would have to do so with a force sufficient to overcome the contractile efforts of the muscles the food, nor could the arteries become reof the stomach, which efforts would be increased in proportion to the quantity introduced. Instead of this, no distending force is required, for there is no resistance offered; the muscular fibres of the stomach become relaxed, and the food falls, as it were, iuto an empty sac. When the gastric branches of the par vagum, viz., those which effect the sceretion of the gastric fluid, become excited, some other nerves must assume an opposite condition; for it is, as has already been said, with nervous influence as it is with electricity; an "ac-

p part, sustained at the expense Fretile nerves of the stomach; the become related the stomach, there-fore, become related the continue so until digestion in the stomach is a lift end, where the order of excitement is reversed. food which stimulated the gastric chemical chyme loses that stimulating property; contractions ensue, by which the chyme is To state here what I believe to be the propelled through the pylorus. I am not so which stimulates to muscular motion. The tracted, the pyloric fibres would contract branches, therefore, or the supposed branch- also, and thus force the contained mass

The contractile nerves of the arteries of The motions effected by the spinal acces- a negative state, in consequence of the exsory are involuntary; those by the spinal cited state of the nerves secreting the gasnerves are voluntary; I have, therefore, trie fluid; hence those arteries, lawing their power of resistance diminished, become distended, and thus present a greater volume of blood to be acted on for the production derived from the muscular and arterial structures of the stomach; for the stomach could not then become relaxed to receive laxed so as to be enabled to furnish, in proper quantity, the materials to be acted on by the excited chemical nerves. During digestion, then, so far as the stomach is concerned, we have an example of the operation of the law of nervous induction. We observe results arising from a negative or an inactive state of contractile nerves, induced by a positive or an active state of certain chemical nerves.

In the spleen, during digestion, the reverse is the case; we have there an active state of certain contractile nerve indud can be effected in no other way than by merves. The spleen is a constitute of certain or any one part by an inactive state of certain chemical can be effected in no other way than by nerves. The spleen is a constitute organ, withdrawing electricity from another part; one can electricity be abstracted from the tion from the pur varian. The this function one without being received by another." branches then, of his nerve, become active, The excitement of the gastric chemical the splenic branches necessarily assume an

of the progres and the duct become rethe other permitting the bile to flow; and the spleen itself, from selasation of its vas-cular structure, theomes enlarged. We observe; that when the process of di-

place in the size of the spleen. It becomes gestion is at an end, the nerves which effect the production of the gastric juice, being no longer stimulated, become inactive, givcessely gaining an increase of contractile splenic branches of the par vagum, recoverpower in consequence of the inactivity of its ling their power of action, recommence their chemical nerves. The cause of the activity labours, which contribute to the process of the gastric branches of the par vagum of sanguification. As by gastric chemical being removed by the food being converted agency the food is converted into a mass into chyme, the splenic branches of the par which is incapable of prolonging the excitevagum again become active, and thus the ment of the nerves which produced the condition of the vascular structure of the ponversion; so, by splenic chemical agency, spleen is again changed, in obedience to the the circulating mass is, by degrees, conlaw of induction. That structure becomes verted into perfect blood, incapable, at relaxed, and, therefore, easily distended by length, of prolonging the excitement of the blood; hence the spleen again increases in nerves whose labours contributed to the persize, as seen as digestion in the stomach is fection of the blood. The splenic branches of the par vagum, therefore, in their turn, It is with the spicen as with every secret- decrease in activity, inducing thereby a proing organ. When the chemical nerves of portionably active state in the nerves which the spheri become active, the nerves which furnish contractility to its vessels, and in convey contractility to its vascular struct the nerves which have a like ganglionic ture assume an opposite condition, whereby origin; consequently, the sphen, as the the vessels become relaxed, and they are blood is perfected, begins to decrease in thus enabled to present to the active nerves size; the ductus choledochus becomes again a greater volume of blood at the time that constricted, by which the bile accoundates blood is required. All glands, during the until again required for admixture with new exercise of their functions, appear swollen, chyme; and the pylorus is forced into strong because at such times their bloodyessels, contractions, the perception of which gives

These are not the fancied effects of the removal of the spleen; their occurrence is confirmed by experiment. The voracity exhibited by animals deprived of the spleen, is so remarkable as to have been noted by almost all who have so experimented. In confirmation of what happens on digestion being ended, from the want of a diverticulum, I shall cite Mr. Dolson:—

"Experiment 1 .- The spleen of a dog was removed. The animal apparently suffered little pain from the operation. On the following day I gave it a quantity of food; it ate voraciously: for three hours afterwards, no perceptible alteration was produced; but in four hours indications of uneasiness were shown, and the animal hecame restless, and at last sunk into a torpid state: it was often moaning; the pupils were dilated, the heart labouring, there was frequent micturition, the respiration was exceedingly laborious, and, in short, there was every mark of plethora, or over-fulness of the vascular system. In the course of two hours from this period, the animal began to recover; and in about three hours these symptoms had subsided; considerable lan-guor remained. The animal took a large meal twice or thrice in twenty-four hours, and after each meal precisely similar effects were presented. The animal became more feeble daily. In a month after the operation it died.'

All the above symptoms might have been predicted; they all arise from morbidly increased contractility. That of the arterial system, causing venous congestion, is too plain to be disputed; the frequent micturion is teatimony sufficient of the state of the bladder. I might here explain the cause of the dog's recovery from the state described, but I think I can do so more clearly, certainly in fewer words, by and-by.

If the remote cause of the symptoms detailed by Mr. Dobson be the removal of the diverticulum of which I speak, it must follow that if we can render a diverticulum unnecessary, no such symptom need appear. The only way to render a diverticulum unnecessary, is to keep up or prolong the netivity of the nerves which secret the gastric juice, and this, as will be seen by Mr. Dobson's next experiment, can be done by feeding at short intervals:—

Bretiment 2. — I next removed the spleen from another dog, but instead of constitution. We know, however, the lightent from another dog, but instead of constitution. We know, however, the lightent form and the last experiment, some chronic affections of the spleen, spleen,

the splenic artery had come the abdonier was healed. Then each of the abdonier was healed. Then each of the same train of symptoms followed each meal, and at the same period, as in the last experiment, though perhaps not so urgent. The animal died in a month from the commendement of this plan of feeding.

There are very many circumstances, independently of facts resting on experiment, which lead to the conclusion that the product of the secreting function of the spleen charges the blood with a great portion of its fibrin. This function of the spleen is foreign to my subject, I shall not, therefore, dilate upon it. I may remark, however, that in certain morbid states of the organ, there is a wonderful deficiency in the coagulating property of the blood, and that, owing to a property of the blood, and that, owing to a want of knowledge of this fact, unlocked-for and unhappy results have followed surgical wounds. An interesting case of the kind is to be found in Mr. Wardrop's lectures, published in THE LANCET for 1833-34, vol. 1. p. 132; it is as follows:-" I attended a patient, where the introduction of a common seton-needle in the side was followed by a fatal hemorrhage. A gentleman, who had an enlarged spleen, was advised to have a seton introduced in his side, and this was done, in the usual manner, by Sir Astley Cooper. Alarmed by the quantity of blood cozing from the wound, I was sent for to see the patient in the evening of the same day. On withdrawing the cord, pressure, carefully applied, with graduated compresses, did not avail, and the hemorrhage being so profuse as to make it appear probable that some vessels of considerable size had been wounded, I thought it expedient to divide that portion of integument which existed between the two perforations of the seton-needle. Having done this, I found that the blood issued from numerous orifices, and I secured no less than nine vessels with ligatures. Blood continued, however, to coze from numberless small orifices over the whole surface of the wound, which every mode of treatment usually employed failed in arresting, and the patient died in a few days." Had the fact, that the blood is deficient in congulating property in some affections of the spleen, been adverted to, the introduction of the seton would not have been advised. In the narration of the above case, the "enlarged spicen" is but incidentally mentioned, the abnormal state of the blood being imputed to peculiarity constitution. We know, however,

for some time back) the hers and unessin spleen, and she has not becaminally during the last year, sanguiteous dejections.

A few months ago I had occasion to order a couple of leaches to the nape of the neck from the remedy. To be really effective in of this patient. I advised that they should be applied in the morning, in order that the the extent of impairing, more or less, the oozing from the bites might cease before energy of the brain. This impairment is bod-time, for I anticipated, from the disorder of the spicen, that it might be troublesome. They were applied at noon, and the blood continued to ooze until two o'clock next morning, before which time she dared to the arteries which were proportionably not go to bed.

As enough has been said of the normal operation of the Law of Nervous Induction, physiologically considered, I shall now attempt to give some instances of its abnor-

discase arise.

A blister being applied to a part of the surface of the body, the scutient nerves there become irritated and excited, and thus an opposite state is induced in the contractile nerves of the neighbouring capillaries. Hence, the power of resistance of these vessels being diminished, they permit of distention by red blood. The irritating cause (the blister) being continued, the relaxation of the vessels increases to such a degree, that lymph pozes from their months, which, being confined by the cuticle which it detaches, becomes a barrier to further irritation. In this simple morbid process lies the whole theory of inflammation, that little-inclusional, though often-handled. subject. The first link in the chain of the diseased action which constitutes inflammation, is a morbid excitement of the sentient nerves of the part; this induces au opposite state of the nerves furnishing contractility to the neighbouring vascular structure; and if the excitement be prolonged, or extended, the opposite condition is also extended to the larger arteries, until, at length, the whole arterial system is involved, and sympathetic fever is established. The most prominent feature of this fever is said to be excitement of the sanguiferous system. Excitement indeed! We see vessels furnished with coats for the purpose of confining and forwarding the contents of those vessels; we see them lose the power of retence, and thus become distended; we see them labour to rid themselves of the distouding said, by frequent, weak, and un-availing contractions, and yot we name their bility, and indisposition to muscular exer-conflict one of exchanges!" If, by "ar-tion. From increased contractility there is resulting the loss of power to act forcitly the content of the small and frequent pulse and

had acted by reducing the force of ar-ticle action, then, as a means of cure, it would never have descended to us; for not one patient could have recovered from the disease, or, more correctly speaking, the cure, venesection must be carried to denoted by syncope, or a state approaching to it, during which the sentient nerves, which were morbidly active, become passive, and those which furnish contractility passive, become active; hence these vessels, having their contractllity restored, are enabled to relieve themselves of the distention under which they labour. Instead of reducing the force of arterial action, we inmal operations, from which the symptoms of crease it; the contractions then become more perfect, and, because more perfect, the contractions become less frequent.

Whatever tends to impair the energy of the brain, and thus, by nervous induction, to increase the contractile power of the arterial system, will be found a means of reducing inflammatory fever. We are told to bleed for the purpose of relaxing the vessels, when it is plain that it is relaxation that ails them. We would bleed in vain, did we not, by so doing, cause a restoration to them of contractile power, in the man-

ner I have attempted to explain.

The remote causes of idiopathic fever, act by impairing the energy of the brain and spinal marrow, or, in other words, by producing a negative state of those centres, and, of course, of all the nerves proceeding from them. By the law of induction, it necessarily follows that some other nervesnerves which have not their origin from the brain or the spinal marrow-do assume an opposite, or a positive state. We look now to the sympathetic system, and we find the contractile nerves all positively affected. The chemical nerves of this system are not affected positively. They are negatively affected, not, however, from the same cause which produced the like state of the cerebral and spinal nerves, but because the positive state of the contractile nerves induces a negative state of them. From this morbid distribution of nervous influence, arise all the symptoms which characterize the first stage of lever. From impaired energy of the brain and spinal marrow, we have listless-

come in columnary; hence arise From the negative state of the chest perves of the sympathetic, there is defective secretion throughout the body, undecar-bonized blood, and loss of animal heat.

Our best pathologists have it, that the remote causes of fever act by impairing the energy of the nervous system. In this there is a fallacy which has proved a heavy drag on pathological research. This error I did not escape when I published on the Nature of Fever, and I therefore endeavoured, with unintentional sophistry, to account for all the symptoms of the first stage, by reference to impaired nerveus power generally. Although I then had some notion of the law of induction, I did not see its application suffiincreased contractile power.

refuge under that miserable philosophy which would have us regard reaction as a negative, or inactive, state of the chemical the system must become defective in quanact as foreign matter, and become a cause of general irritation. Scooner or later the irritation. They become excited, and thus is the order of operation of the law of in-duction reversed. Contractility, which be-fore superabounded, now becomes deficient; hence the arteries, from a state of constriction, lose their power of resistance, and hecome distended. This negative state of the contractile nerves now induces a morbidly active state of the chemical nerves; hence the great increase in animal temperature, the highly florid state of the blood, and the vour. acid nature of the secretions.*

With regard to Mr. Dobson's experiments. I said that all the symptoms denoted morbidly-increased contractility, and, consequently, that there must have been a negative state of the chemical nerves. vitiated products of secretion would then become the irritating cause by which the order of induction was reversed. The animals, however, must have laboured under febrile symptoms until again fed, which, doubtless, was the cause of the "considerable languor " which remained.

I must here conclude. I fear that I have already encroached too largely. If there be

simply pointed it out. The fifties in the bulunes. If the not such a law, I have said see much.

HAHNEMANNISM.

To the Editor of THE LANCET.

Sin: Having lately seen some notices of Hahnemann's new doctrine in your valuable Journal, I forward to you the following observations for insertion.

Bold, but inconsiderable and despised, ciently clear. Blinded by specions authority homocopathy originated at the beginning and early impressions, I argued impaired of the present consury. Opposed, as its nervous power from symptoms, nay, signs, of doctrines were, to all bitherto required ideas, it necessarily met with the opposition Reaction takes place, and the second of the medical world. Hahacmann's prostage of fever is formed. Let us not take position of axioms, the blind acceptance of which he required from his followers, could not but be disgusting to the better part of specific principle, according to which the the profession. The proposed abolition of first stage becomes the immediate cause of all that had before been held to be true, the the second. It is evident, that during the mysticisms which obscured the whole system, and the wandering life of the author, nerves, the products of secretion throughout were all calculated to keep back disciples. At first, therefore, only such medical men tity, or in quality, or in both. They must thus as did not think for themselves could be gained over to the new practice. Peculiar circumstances, however, favoured its exsentient nerves become alive to this cause of tension. Among other causes, perhaps a chief one was, that many were disgusted with Brown's system, which at that time was at its height, and they thus embraced the opposite extreme. But, also, it was a time for systems, and, for many purposes, this one answered just as well as any other, I do not wish to say, that all who followed Hahnemann were insincere, or did so blindly, but I am forced to say that, for the greater part, little can be said in their fa-

Every scientific reader of Hahnemann's works, which chiefly treat of chronic dis-cases, for which he allows three causes only, must perceive, at the first glance, that all he says amounts to assertions merely, for hitherto the proof has been wanting, and the only conclusion to which we can come is, that Halmemann has rejected all that was received before, without giving us in its. place anything but a list of effects of media. cines on the healthy. On these the homeopathic practitioner is to found his rules for treating any given case. Of a pathology. treating any given case. Of a parton of the an only given us some fragments. Of the action of the parton of the pa sent since medicine became a science, yet

Charletti

re must laugh at the ridiculous ion of those men who discar lease. The Hamenanness, then not only pose medicinal science, but they discard he natural curative process; and yet they discard he natural curative process; and yet they all their treatment the most conformable ith nature! To try the effects of speci-ines on the healthy, is a suggestion of fahnemann's creation. Before his time emedies were observed with regard to the ick only. In some instances their effects, ertainly, were known on the healthy, as cell, but more from accident than in conequence of investigation. Hahnemann, bserving that remedies taken by healthy ndividuals produced symptoms similar to hose diseases against which they were used, ounded upon that observation his doctrine f "similia similibut," making it a general ule to employ in each diseased state such emedies as would produce the symptoms of similar malady in the healthy. A priori, he correctness of this position cannot be lenied. Traces of it we find in the ancients. for instance, it was known that the too free ise of quicksilver against lues, produced a lisease similar to lucs. It was but natural hat Hahnemann's system should be very imperfect in the beginning, it being one foun led in observation, and consequently requiring much time to perfect it. Whether, however, the conclusions thence drawn be true, ir whether the axiom be only true as regards certain remedies, must yet be proved, and only time and many experiments can lecide this question either way.

Halmemann, wishing to observe the effects of different remedies, was obliged to give them pure, i. e., without admixture. And herein consists one of his chief merits with regard to the amelioration of medical science. Before his time remedies were given in such marvellous, and often such absurd compositions, that the effect of each ingredient seldom if ever could be ascertained. This appears the more surprising, as some of the most distinguished practitioners always preferred the simpler forms of prescription. But it seems that the generality of medical men rather copied recipes which were recommended by some authority or other, than thought for themselves. I do not, however, wish to be understood as condemning all compositions, for the value of some has been tested by long experience; but if we consider what ridiculous reasons became the grounds for the adoption of different remedies, often only the taste, the feel, the colour, or even the form of the we cannot soo highly prize the labours of the man the paternsted to ascertain the

a great deal more than any agetem ever did before. To find the pecifics is also a merit of Habnemann and his followers.

We now come to that part of the homeopathic system which may be considered the most absurd, namely,—that the smaller the dose the more intense should be the effect. This assertion is also quite novel, and until Hahnemaan has established it on better proofs than have hitherto been afforded, every thinking practitioner must see its feebleness; and, to say the least, it must be confessed that Hahnemann has gone too far in his proposition. There can be, however, no doubt that before Hahnemann, many practitioners have given medicines in unnecessarily large doses, and, in many cases, if they did not observe the desired effect, they continued increasing the doses, not ascribing the failure to their injudicious choice, but to the smallness of the quantity, and so went on, not only failing to cure the evil, but often increasing it, and adding new ones; and though Hahnemann fell from one extreme into the other, we must allow him the merit of being the first to draw attention to the abuse, and of having done all in his power to diminish it. That anything is effected in homosopathic practice with very small doses, may arise from the fact that very powerful remedies, and chiefly in the form of tincture, are used by the disciples, and also that the system of the patient has become very sensible to medicine, in consequence of the exceedingly strict diet enforced.

Of this latter we must say a few words. Much mischief, without doubt, has herein been done by omission. Many medical men have hardly the courage to insist upon a strict diet. Many think it of no importance. The idea of dieting is almost as old as medicine itself, but to abstain from certain spices and certain dishes belongs to Hahnemann, and is new, inasmuch as it regards only the quality and not the quantity. What Hahnemann says with respect to the preservation of health, is hardly worthy of notice, and has as yet only been used to advance some quackery or other. I speak of his hygeine, which recommends the adoption of a certain diet in order to prevent disense.

some has been tested by long experience; but if we consider what ridiculous reasons became the grounds for the adoption of different remedies—other only the taste, the chiefly drawn from authorities better intended, the colonr, or even the form of the we cannot soo highly prize the labours of the many the attempted to accordant the sanct open attempted to accordant the reaching the colonry of the many the attempted to accordant the reaching the colonry of the many the attempted to accordant to the many the attempted to accordant to the many the attempted to the colonry of the colonry

DOUBLE VISION.

To the Editor of THE LANCET.

Six: On reading the account of the case of double vision in your Number of the 27th ult., I have thought it might interest some of your readers, to detail what occurred to

myself of a smollar nature.

In August 1831, during intensely hot weather, I was travelling alone in the Malle Poste from Bordeaux to Paris (a journey which is not performed in less than sixty hours, including the long stoppages on the road), when, on the second day, I was rather surprised at perceiving the distant rows of trees in double lines, one above the other, which at first I thought was attributable to the badness of the glass of the windows, which were closed, but upon opening them I found to my surprise, that the cause existed in my own vision, and upon trying the effect of opening and closing each eye, I found clearly that both eyes were similarly affected, but the left much more so than the right. It, however, only seemed to attach to distant objects, for persons or cattle near the carriage I saw perfectly distinct as usual. This state continued until I reached Paris, when, thinking it might be occasioned by want of sleep (not being able to repose in a vehicle), I concluded that a day or two's rest would carry it off; but after that period, finding myself unable to look at any thing steadily, and that the left eye had in its white part a yellowish spot as big as a pea, whilst my bowels were much confined, and my head at the crown fest uneasy, and with a kind of strained feeling, I sent for a medical gentleman, whose name I forget, but who immediately wished me to be cupped. To this, having an unconquerable aversion to lose blood, I objected, but permitted him to physic me ad libitum, which he did, and by so doing, unloaded the bowels, and a little relieved the sight; but on my arrival in London a few days afterwards, I found all the symptoms return, and my sight so much affected, that I could not recognise a friend at a few yards distance. Fearing, however, that this evidenced a tendency to apoplexy, I now consented to be cupped, which gave me but temporary relief, and it was not until two months had elapsed, that the affection wore off, which it did gradually, and I have never had a return of it, to our product. My eyes are a bluish grey in colour, and cate to you the follow my sight has always been remarkably good. They in a very curiou

of accretoned of Fran exercise, herr always a stone been accustomed to much exercise, both squestrian and pedar trian, and nothing deranges me more than confinement in a carriage for any length of time. My living is always temperate. I am, Str. your obedient servant.

A CONSTANT BUT NON-MEDICAL READER. Stoke Newington, March 3, 1836.

SYPHILIS.

To the Editor of THE LANCET.

Sin: My attention having been directed to some observations on syphilis, by Mr. Eagle, in THE LANCET, No. 651, I take the liberty of proposing the following questions to him, and to those who advocate the same opinions.

Mr. Eagle assumes, " that many effects imputed to venereal poison are produced by mercury." How is it, then, that of the tens of thousands who are daily taking mercury for other diseases, numbers are not similarly affected?

If the venereal poison be not absorbed, how can the system be contaminated?

What evidence has Mr. Eagle to prove that chancre will produce gonorrhora, and gonorrhiea chancre? I am aware that the common answer is, that "Two individuals may have connection with the same woman. and the one have chancre and the other clap." But gonorrheeal and chancrons matter may be left in the vagina from previous intercourse. Indeed, I have known a healthy female communicate the disease, which could only have arisen from this cause

With regard to mercurial rheumatism, I am not yet a convert to the doctrine of Hahnemann, viz., that a disease is produced and cured by the same medicine. Lastly, I have met with nothing to shake my faith in the mercurial treatment of syphilis, and, I may add, that the opinions of Messrs. Guthric and Rose are in opposition to those of the majority of British practitioners. I am, Sir, yours respectfully INVESTIGATOR.

March 7, 1836.

PROPOSAL OF LIGATURES TO MANDE

To the East terest which you completely takes away, I think those Fare the honour which

him by all surgical leading baving been the first the Table and the same to bleeding vessels. The work is entitled Gabelhover's Boocks of Physicke," and was first translated into English in the year 1559, being twenty years before Ambrose Pare's account was published. The following is the extract, taken from page 30% being the commencement of the fourth part:
"In then ther he arms rappe discided or

heyved a sunder, you must then knowe that both the ender of the vayne which is discided doe dravve themselues vpvvardes in the flesh, whereof you must indevour. with little instrumites fit for such a purpose, to take houlde of that ende of the vayne which is shrunk up into the greater parte of the bodye, drawe it forth, and with a crooked needle, to sticke it, and soe to binde it," &c.

I trust you will not think this communication of too little importance for insertion in your valuable periodical, as the explosion of any error, even in the history of our profession, cannot be void of interest. I remain, Sir, your obedient servant.

JOHN MOORY NELIGAN. 5. South College-street, Edinburgh; March 5, 1836.

CHEMICAL AND PHYSIOLOGICAL RESEARCHES

UPON THE

BLOOD OF THE VENA PORT.E.

PROFESSOR SCHULTZ has communicated, in Rust's Magazin für die Gesammte Heilkunde, the results of some interesting chemical researches upon the blood of the vena portæ. In the first part of his memoir he publishes the results of his experiments upon the portal blood of horses, of which the following is a succinct account. He states that

1. The blood of the vena portse is in general more dark than venal blood, though this difference is not always very distingnishable. It is not reddened by solutions of neutral salts, nor by the contact of atmospherical air, nor by the action of oxygen

The period blood does not congulate, or do see at sing time, it forms cakes, of which the does not congulate the does not congulate.

is sver which we find a vo-

startily speaking, portal blood contains 5.23 per cent in a fresh state, and 0.74 per cent in a dry state, more of fibrin than other veral blood, or arterial blood.

4. Liquid portal blood in general contains less solid particles than other venal blood or arterial blood, i.e. 0.18 to 0.3 per cent. 5. The serum of portal blood generally contains 1.58 less of solid particles, than that of arterial blood, and 0.80 less than that of other venal blood. The first, in a dry state, has an ash-gray colour, the se-cond is yellow, and the third a yellow-

6. Portal blood contains proportionally more crassamentum and less albumen. The contrary obtains in arterial blood. The dry crassamentum of the vena porte is gray and brown in colour. That of other veins is deep-red, and that of the arteries is bright-

7. Portal blood contains nearly double the quantity of oily matter that is contained in arterial blood, or blood of other veins, viz.,

> In portal blood 1,66. In arterial blood 0.92. In blood of other veins 0.83.

8. Dried serum of the vena portæ contains only 0.27 per cent more of oily matter than the dried serum of the arteries and other veins.

9. We find in albuminous crassamentum more albumen by 1.11 per cent than in arterial blood, and 1.21 per cent more than that of the other veins.

10. It is with respect to the quantity of filmin that the greatest difference is found. Dried fibrin of the vens ports: 10.70 per cent of oily matter; that of the arteries 2.34 per cent, and thus upon the whole the difference is 8.36 per cent.

11. The oily matter of portal blood is brown, black, and unctuous; that of the arterial and of other venal blood is white, or yellow-white, and crystalline; that of chyle is white, two-thirds liquid, and one-

third crystalline.

On perusing the paper which contains these statements, the absolute necessity for the adoption of some standard with respect to the fibrin is rendered very obvious. are aware that after fibrin is dried in the usual manner, the process may be continued until it has become one half less in weight, although the external character shall not be changed. Were the fibrin pressed and dried with a towel, its comparative weight in dif-Wish the portal tained, and all we should have to do would blace the live first either be to establish a standard as to the quantity wholl; have the worky-four of the fibrin when collected from the blood, which is a stollar manner to the in the usual manner, and the press and portal blood, which does not congulate a weight of lead employed should also be determined When we wish to standard for normal blood with whi ought to compare diseased blood, we ought to work quantitively, by giving, in separate items, the water, the crassamentum, the fibrin, the albumen, and the salts. Such are the rapid changes which diseased blood; perticularly, undergoes, that we are compelled to use this plan, for if we enter into such minutie as LECANU gives us in normal blood, not one chemist in a hundred would ever attempt such a task, nor would the rapidly decomposing blood of a diversity of diseases permit even LECANU himself to investigate any simple disease in such a uselessly minute manner. When we are about to ascertsin the gases contained in blood, or any other organic fluid, we should take ten ounces at least, in the manner recommended by Dr. CLANNY in this journal, and submit them to the action of the air-pump. His method of analysis of blood in our pages is also worthy of attention.

EXAMINATION OF FIESCHI'S HEAD.

On the 21st of February, Dr. Lelur, physician to the Bielfre, proceeded to examine the head of Frescht, who had been executed on the Place St. Jacques, at eight o'clock on the morning of the 18th. There were assembled a considerable number of the notables in phrenology, advocates and adversaries of the system, and a few literary men and painters, but not a single surgeon.

The cranium presented exteriorly the marks of two wounds, one of which was situated over the postero-superior angle of the left parietal bone, and occupied a contilerable surface; the other, much smaller, was seated a little above the extremity of the left eyebrow. Near the angle of the mouth, on the left side, was an oblique ciatrix, nearly half an inch in length, so completely formed, that it might have passed for the mark of an old wound. The external wound of the integuments, above the ear, was not yet closed.

The soft parts were now carefully removed by a crucial incision, and the bone exposed. At the point corresponding with the wound in the left parietal bone, was observed an oval projection of the osseous wall, as large as a crown piece; this prominent portion of the bone was perfectly circumscribed, and bore some resemblance to a watch-glass fixed in its circle. Its surface was throughout uniformly convex, except at a small

On outting through the its internal surface. a concave space oper tame form and dimensions corresponded with the external projection, and it now became evident that the latter was nothing else than a portion of the skull which had suddenly and in totality been removed, as it were, by the action of a punch, and being at once replaced by the surgeon, had subsequently united to the rest of the cranium. A very thin false membrane lined the internal surface of the fractured bone, and separated it from the dura mater; however, the membranes of the brain near the wound were perfectly healthy, and presented trace neither of external lesion, nor of inflammation. It was evident the brain, had not been injured, a circumstance which explains how the assassin was able to descend from his chamberwindow by a cord into a neighbouring court; yet the shock must have been dreadful. The wound on the forehead seemed only to have entered the external wall of the frontal sinuses. Firscui, during his trial, spoke of seventeen or twenty fragments of bone which had been removed from his head; this was an exaggeration, if not false, for nowhere could any loss of substance be perceived.

The nature of the wound, and particularly its mode of union, offer several particularities of the highest surgical interest. No doubt M. LELUT will shortly publish a detailed account of the autopsy; in the mean time we have taken the above remarks from the last number of the Gazette Medicale, which, as usual, endeavours to show that FIESCHI's head is a complete refutation of phrenology. According to the Gazette, Fiescur's head is completely insignificant in a phrenological point of view. Its absolute volume is very ordinary, while the relative proportions offer nothing worthy of fixing the attention; the forehead is ignoble, the lateral diameters are very short. There is only one single organ evidently developed-viz. philoprogenitiveness ? that of habitativity also is active. The organs of ranity and pride do not present any proi jection of note, although those two pass were certainly the key stone of his whole moral machine. The tr alithere occasions, art

RESEARCHES INTO THE DISEASES OF CHILDREN.

CONDUCTED ON THE

1 KNOWN PRINCIPLES OF ANATOMY AND

CHOREA.

CHOREA, or "St. Vitue's dance," as it is popularly called, is a disease which very seldom terminates in a fatal manner, and it is only occasionally-at very distant intervals -that children abouring under this affection are cut off by some supervening malady. We have had occasion to observe only two necropsies of children who have died while affected with chorea, and the results of an examination were completely negative. The symptoms of chorea are well known to all practitioners who have had the slightest experience in the diseases of children; we shall not therefore recur to them here, or to its treatment. The remedies which have been at different times employed in chorea, are very different. Since the time of Drs. HAMILTON and PARR, purgatives have, we helieve, been the favourite remedies with English practitioners, who, amongst the multifarious accidents which they attribute to disorders of the digestive organs, foul bowels, constipation, &c., rank also chorea sancti viti. It is the opinion of Unnumwood that it should be so ranked, and of his last "cditor," who seems inclined M. BAUDELOCQUE, who has since continued to superadd want of tone in the system. We do not mean to assert that certain cases of chorea may not depend on irritation of the sulphurst of potass to a common bath, the intestinal canal, for such we suppose to in which the patient is placed for an hour. be the translation of "foul bowels" into Fifteen to twenty baths are in most cases medical language: but we are strongly inclined to regard the opinion as erroneous, the month of September 1832 to the month which would attribute chores in a general of January 1833, fourteen girls were treated manner to derangement of the digestive exclusively with the sulphur-baths, one every system. On the contrary, we are disposed day excepting on Thursdays and Sundays. to confider it as essentially a disease of the Of these fourteen, thirteen were perfectly nervous casting, occasionally depending on cured, and the mean duration of the panot yet such advanced to be able to method can furnish such favourable results. In the treattrue, the prosting of the pros

li-conclusion that choren de-Supen "worms, foulness of the wels," &c., and that we must torment our patient with a course of mercurial or alostic purging. If a large number of cases of chores be cured by the purgative method, it is because chores, like certain other neryous affections, yields, generally speaking, to any strong impression made upon the system, and not because the disease depends immediately on disorder of the digestive function, removed by aloes or calomel. We are induced to make this assertion, which will probably appear heterodox to many disciples of the purgative school, by the fact that we have seen a vast number of cases of chorea (of all descriptions, and taken indiscriminately) treated by the simple means of cold effusion, and with the most happy results. For the last few years baths have been the favourite remedy at the Hopital des Enfans Malades. They are administered under various forms; cold-baths at the ordinary temperature, immersion-baths at 150, and sulphureous baths. MM. JADE-LOT and GUERSENT, who have the care of the scrofulous patients during the winter months, and do not take charge of the acute wards before the arrival of summer, are in the habit, the former, of employing cold baths, the latter, immersion-baths. Whenever any apprehension is entertained of the existence of bronchitis, either in the acuta or chronic form, M. Gurasun replaces the immersion-baths by sulphureous baths, a remedy proposed about four years ago by constantly to employ them. The sulphurbath is composed by adding about 4 oz. of rufficient to remove the disease. Thus, from pritation, but in a vast majority of cases tients' sojourn in the hospital was only saced by causes whose influence we are twenty-four days. We doubt if any other simployed, it is Should the disease resist the administration

JOHNSON STREET

of ten or twelve baths, M. BAUBELOGEORA accustomed to add the subcarbonate in fron interiorly. During the course of the malady he prescribes a substantial diet and a double ration of wine. The ordinary drink of the patient is an infusion of linden leaf and orange flowers MM. GUERSENT and JA-DELOT sometimes administer the oxide of following she took two other baths, with the zinc, valerian and meglin pills (composed of Qs. Zinci et Valer.) The acetate of admission, an evident improvement had morphine has latterly been tried in four taken place. She can answer a few ques-cases, but without any advantageous re- tions, and put out the tongue, with considersults. Purgatives are given in all cases where constipation exists, or whenever less irregular, but still the patient is unable the presence of intestinal worms is suspected; and if there be any symptoms of sulphur-bath is administered every day; the plethora, some blood is abstracted from the drink, infus. lindæ et flor. orang. On the system. The following cases, to which we lat of February the child is able to get out might add several others, will serve to illus-

Bathe : Rapid Cure.

A young girl, ten years of age, recently ar- improved; the movements of the tongue rived from Auvergne, of tender constitution, become natural; a sulphur-bath is adminismild character, and excessively timid, was tered six times a week. The diet is non-suddenly frightened on the evening of the rishing, and on the lath of February the 10th of January, by a boy who had concaled himself in a hall for the purpose of tetrifying her. The girl let fall the utensil she carried in her hand, and at the same thousant was seized with irregular moveof the Body: Four Relapses: Sulphur-Bath ments, and a complete paralysis of the left; arm. From the 12th to the 15th, the movements became more irregular and intense; Sophia Mollet, thirteen years of age, of the left leg became feeble, and the patient delicate constitution, small stature, not has dragged it after her in walking, like a paraing yet menstruated, was received into the lytic person. Her gait is vacillating; she is hospital about the curl of September, labour forced to catch hold of the farniture to pre- ing under chorea for the fourth time. Th vent herself from falling. During the first first attack came on at the age of four year two or three days the parents, who had no and continued for a month; the second a suspicion of the existence of disease, were the age of seven; duration unknown; the constantly reproaching the patient for her third attack at the age of ten, continued for awkwardness; a circumstance that con-three weeks, and was cured by cold bath siderably aggravated the accidents. On the The invasion on these three occasions too 17th of January the irregular movements place without any known cause; the disea had affected the four limbs, the muscles of the face, the tongue, and the faryux; progression was constantly developed in a slow and property of the face, the tongue, and the faryux; progression manner. The fourth attack, and not articulate distinct sounds. She was brought to the Hopital des Enjans Malules imenced about six weeks back; it con brought to the Hopital des Enjans Malules imenced on the right side of the body, as on the 19th; her state now seemed very did not extend to the left side before a lay atarming. The child was a prey to the of three weeks; about the thirty-fifth d adarming. The child was a prey to the of three weeks; about the interpretarion. It is with difficulty that she could be confined in two beds placed one beside the other, and placed in an angle of the ward. She is unable to speak, or keep the head for an instant in its natural position; it falls to the right or left side, as parent's account, the state of the muscles of the neck were paralyzed. if the muscles of the neck were paralyzed, of constant grimace; progression is irres. She is unable to sit up in bed, or maintain lar, and the patient fell down street in

seessively embarrassed, and the the pulse. In the morning, immediately after her arrival; the patient was placed in # sulphur-bath, and kept there for an bour and a haif. On coming out she was a little calm; in the evening a second bath; the day sulphuret of potass.

On the 23rd, four days after the patient's able efforts; she took a few spoonfuls of to seize a single object with the hands. A of bed alone, and walk about. On the 5th no trace of the disease remains, except some CASE 1.—Intense Chorea, with Imperfect
Paralysis of the Limbs; Muliam; Sulphur.

Buth. Dail Comments of the Limbs in the limbs of the Case of the Limbs in the li regular; pulse constantly calm. From the 3rd to the 15th, the general force is much

> Cure after Nine Weeks' Illness and Thre Weeks Treatment.

that position when placed in it. The re- they to the hospital. The fingers are

sonstant movement; the m sumswhat reduced : any plack of derangement. On the day after admission, the patient submitted to a course of tepid sulphur-baths, each bath for half an hour; she was placed on half diet. Up to the 1st of October there was an appearance of amendment; the baths were now prolonged for an hour, full diet was allowed, and the quantity of wine doubled. Under the influence of this treatment, the nervous symptoms completely disappeared, and the girl left the hospital on the 15th of October completely cured.

We omitted to mention that the father of this child had been affected with violent chorea near the age of puberty; her mother was never subject to any nervous disorder, and presents all the appearance of perfect health.

PLEURO PNEUMONIA ON THE BIGHT SIDE. COMPLICATED WITH PERICARDITIS.

Isidore Loiseau, six years of age, of good constitution, had been convalescent of some cutaneous eruption with which he was affeeted, for several months, when he commenced to cough; to complain of pains on the loins; to exhibit symptoms of fever and dyspinea; these symptoms persisted, and augmented during eight days, when the pa-tient was transported to the hospital with the following symptoms :- Face slightly vellow, expressing much anxiety; dilatation of the nostrils at each inspiration; cough dry and frequent; no expectoration; respiration deep, costal, seventy-two in the minute; percussion gives a dull sound along the whole of the right side posteriorly and laterally; souffle tubaire, and bronchophony in the two superior thirds; on the left side the sound is clear, and on anscultating we hear nothing but some uncous and subcrepitating role; the skin is warm; the pulse small and feeble, 140; tongue broad and moist; abdomen painful to pressure; two to three liquid stools every twenty-four hours; during the tright insomnia, disturbed cries, partial delirium. In the morning we find the intelligence clear, the senses of hearing and seeing intact; when asked where he suffers, the little patient says every where; when we ask him to point out where he suffers most, he places his hand on the back; the physician diagnosticates pleuro-pneumonia, in the second degreet Infusion of Mallows two puts; Gum-

During the day the anxiety continued as before : some dyspness : some alteration of the countengant, the patient seems very sensible to manufact on the blisters.

January 6. Takenage is pair; the lips are blue; decubites since the commencement of the disease; dorsal respiration more accele-

we count up to 80 insurations in a minute. The pulse is too feefile and quick to be counted. The feeble state in which the little patient lies does not permit us to examine his chest; death supervened during the night.

Autopsy. — On examining the body, we find the three lobes of the right lung united together by false membranes, which are soft and easily torn. The surface of the inferior lobe is entirely covered by an alliaminous exudation of a slightly yellow colour, in some points at least two lines thick, and uniting it to the pleura lining the diaphragm. The cavity of the pleura does not contain any liquid. The pulmonary timue of the three lobes is completely impermeable to the air, is dense, and sinks rapidly in water; when pressed between the fingers it does not discharge any fluid. On the left side we do not observe anything more than a slight congestion of both lungs posteriorly; the anterior part is healthy, it presents a little interlobular emphysema. The bronchi are gorged with puriform mucosities, and the lining membrane is of a rosy colour; the bronchial glands are healthy; we do not observe in them any tubercular deposit.

On dividing the pericardium we find the heart enveloped with a pseudo-membranous exudation, reticulated, and of a yellowishwhite colour; this is prolonged as far as the origin of the great vessels. The internal lining of the pericardium is covered with a similar exudation, though not reticulated, as in the heart. The tissue of the heart is soft and discoloured. In the interior we find some dark imperfectly congulated clust; the large vessels are free from disease Neither the brain nor the organs contained in the abdominal cavity present anything worthy of notice.

This child was brought to the hospital in an advanced stage of the disease, and the symptoms which he presented did not leave any doubt of the existence of pulmonary disease. Auscultation and percussion of the thorax clearly indicated its seat, its nature. and its degree, and even determined its precise extent. The inflammation of the pulmonary parenchyma having appeared to account satisfactorily for the dyspaces and other accidents, our examination was not carried further than was necessary to determine the lesion of the lung. The precordial draught, with White Oxide of Antimony, and region was not submitted to percussion or auscultation, and hence the existence of infiammation of the pericardium was completely overlooked, and not suspected before the examination of the body after death. We are not to conclude from this that pericarditis is a latent malady in children, for in several cases, where the disease existed free from complication, it has presented # same characteristic signs as in the adult, was recognised during life.

LARYNGITIS, BRONCHITIS, LOBULAR. PNEUMGNIA

Joseph Danian, seven years of age, of good constitution, had suffered under a very irregular rubeola for five days, when he was brought to the hospital on the 16th of October, 1835. Being examined at the visit of the following day, he presented the follow-ing symptoms:—Face purple-coloured; respiration extremely embarrassed, 54 in the minute; decubitus, variable sometimes on the right side, sometimes on the left; cough moist, but no expectoration; voice nearly gone; rale crepitant on both sides of the chest; sonority normal; no bronchial respiration, or local pain; tongue covered with a whitish fur; lips dry and cracked; great thirst; belly free from pain; no stool; the intelligence is not disturbed; the child ansome trace of the eruption on the limbs; the pulse is small and accelerated, 130. The diagnosis given is, "laryngitis, bronchitis, with congestion of both lungs." Ipecacuanha each leg; Infusion of Mallows for drink.

18. During the day of the 17th the child vomited twice, and passed five stools con-taining two lumbrici. The evacuations gave to speak. rise to but little benefit. Asphyxia is now imminent; the colour of the face is extremely blue; the pulse 150, respiration 56. The in children below six years of age. We cough and alteration of the voice the same are not aware that it has been described by as before; no expectoration. The stetho- any of our English writers on the diseases of scope furnishes the signs already noticed. When we place the ear on the little patient's chest we distinguish a very well-marked râle crepitant. Gum Infusion, with Tartar An-symptoms have been determined by careful tim. gr. vi, and Syrup Papaver. 3i. No observation at the Hopital des Enfans Malavomiting produced; during the day two or | des. We shall recur to this affection again, three involuntary stools. Died in the night.

Autopsy .- On opening the body twentyeight hours after death, we observe a violet tint of the integuments covering the posterior surface of the body, and of all the upper part of the thighs. No cadaveric rigidity; the arachnoid is moist and in a normal state; the subarachnoid cellular tissue is infiltrated with a small quantity of serum; the glands of Pacchioni are very numerous, and the veins on the surface of the brain gorged with blood, the cortical substance of the hemispheres is much injected, and when the white substance is divided it presents numerous bleeding points. The consistence of the cerebral pulp is normal. The whole of the mucous membrane lining the air-tubes is red and thickened, from the epiglottis to the minute bronchial ramifications; the latter are filled with a viscid and bloody mucosity. We do not observe any trace of its frequently deprived of a parish, or pawhole of the mucous membrane lining the

le membrane in the pieura congpitant; their tissue rosy : their there by some purplish spots, which are much disseminated posteriorly, while in front they are more close. On pressing the pulconary substance between the fingers, in feel some small nodules, varying in volume from the size of a pea to that of a nut. On dividing the substance of the lung itself, we find the greater part of its sissue healthy, and that the nodules alluded to are so many points of hepatized tissue: they exist in both lungs; there is no very remarkable congestion; no tubercles; the heart and its membranes are in a normal state; abdominal organs healthy.

The pneumonia in this case, instead of attacking one or more lobes of the lung, as in the preceding observation, was disseminated, and constituted what in France is called "lobular pneumonia." The affection presents certain negative characters, which swers clearly when addressed; there is still the physician should always bear in mind. Thus, although the pulse and the respiration were excessively rapid (150 and 56), the chest gave a perfectly clear sound on pergr. xii; Antim. Tartar. gr. 1. One blister to cussion, and we did not observe anything approaching to the souffle bronchique. The presence or absence of broncophony could

Lobular pneumonia is a frequent disease children, and it is only within the last few years that its anatomical characters and symptoms have been determined by careful and when we shall have published a certain number of cases, we propose to give a general description of lobular pneumonia.

P. H. GREEN.

ATTENDANCE ON THE SICK POOR.

To the Editor of THE LANCET.

SIR: I have paid much attention to the various plans suggested for giving efficiepattendance upon the poor, under the new Poor-law system, but find none of these plans sufficiently simple, or mastended by some great objection.

3. 2. Fr. 1.

rithes, which he has been in attending; and the to his residence, have, in some degree, remunerated him for his trouble; and he is obliged, if he take a district at all, to attend parishes at such a distance from his abode, as renders his contract altogether unprofitable, and very injurious to the poor thems solves, who have so far to send both for advice and medicine. Local dispensaries I consider altogether useless.

From my experience of the simple working of the self-supporting institution in this town, I am satisfied that the nearer any plau can be brought to the one adopted in that institution, the better it will pay the practitioner, and the more satisfaction it

will give to the poor.

Let the Unions be composed of parishes, as conveniently situated as possible for the medical practitioners. Let the number of paupers in every Union, who have, on an average of years, required medical attendance at the parish expense, be ascertained; and, according to their number, let a sum be fixed which may be considered a fair remuneration for the yearly medical attendance upon all the paupers of such Union.

Instead of giving a certain number of parishes to any particular surgeon, let every pauper, when taken ill, apply to the overseer, or the retieving officer, whose duty will merely consist in giving a certificate to such applicant, "that he is a pauper of such a parish." The pauper will then be at liberty to take, or send, this certificate to any surgeon whom he may prefer (who may have agreed to attend the poor of his Union), and he will, generally, to spare binself trouble, apply to the nearest resident.

Let every surgeon preserve these certificates, and at the end of the year or half-year; let him be paid his proportion of the sum fixed for the whole Union, according to the number of certificates so held, without any reference to the nature of the cases he may have had under his care. This plan, taking trifling cases and severe ones togother, will be found a very fair one, and the overseer, or relieving officer, will no longer be called upon to judge whether any applicant may be a fit subject or not for the doctor.

The sum fixed upon for the Union must, in some degree, he regulated by the distance from the medical practitioners, as well as the denseness of the population. In a town of considerable size, the poor can be taken much lower rate than in country districts, where the surgeon may have to travel many miles to see his patients. I remain, Sir, your years the surgeon the surgeon statement of the surgeon statement of the surgeon statement of the surgeon may have to travel many miles to see his patients. I remain, Sir, your years and surgeon for the surgeon su

many miles to see his patients. I remain, Sir, your very stiglest servent,

PARTIES OF THE NECESSITY FOR REGULATING

MEDICAL ATTENDANCE ON THE SICK POOR,

ON JUST PRINCIPLES.

To the Editor of THE LANCET.

Sin: I have perused with considerable interest the letters of your intelligent correspondents, "Ruricola" and Mr. Yeatman, on parochial medical contracts, and beg to offer a few observations on the mode of appointing medical officers.

It is proposed by "Runicola" that medical men be appointed by the rate-payers; and by Mr. Yeatman, that they be

clected in rotation.

With regard to the first proposition, I think it would be adopted with advantage in large towns, where the rate-payers are more independent than in villages, but in the latter places it would only favour monopoly. In villages there is generally one individual who takes upon himself the office of parish ruler, and the rate-payers (many of whom are tradesmen, and derive their support from him and two or three other farmers) are obliged to vote (if they vote at all) for the nominee of this great man. Favouritism and jobbing must, necessarily, be the effect of such a state of things. Under the new system, viz., the election of surgeon by the guardians, mo-nopoly exercises its baneful influence; and I think I can furnish a strong case, proving how necessary is the adoption of Mr. Yeatman's proposition, viz., that medical men should be appointed in rotation. I am living in Broughton, a large village containing nearly 1000 inhabitants (situate only three miles from the far-famed borough of Stockbridge), and it has been for many years the residence of two surgeons. It was customary with my predecessors, and the gentleman who is now living here, to attend the poor of the parish alternately, which arrangement afforded satisfaction to all parties. On my commencing practice, I of course applied to be appointed in my turn to the office of parochial surgeon, but I was told that the arrangement above mentioned would not be acceded to, -that the gentleman who was in attendance would so continne. For this unjust proceeding I could gain no satisfactory reason or explanation, but I at length was informed that the influential man had placed his son with, or was about to apprentice him to, the favoured medical man. Now, Sir, I was no stranger to the poor; I had served my apprenticeship in the village, and, as is the case with most pupils, it fell to my lot to mix with them, and, in administering to their necessities, I studied their feelings; and I am proud to

y, Chudleigh, De

say, that though they were cooded in gaining their good will

support of the assertion, that the benefit of as Mr. Jervis and the late recorder take a

gentleman, at the earliest moment practi- parish officers previously to giving our atcable, rose and proposed that his favourite tendance. To ensure the future method of carried. Here was a deeply-concerted cases of pappers. In the cases of respectmedical contract would be entered into at morie, I connot suggest, the first meeting; consequently, there was by Mr. Yeatman, as the only one likely to spectfully, destroy favouritism, jobbing, and monopoly, the existence of which must always prove injurious to the pauper patient.

There are some other points connected with the administration of the new law, which I shall take the liberty to state to you at some future opportunity. In the mean time you will, perhaps, find a corner in your independent journal for the above. 1 your independent Justice, am, Sir, yours respectfully,
L. Owen Fox.

Broughton, Stockbridge, Hants, March 8, 1836.

LAW RELATING TO ATTENDANCE ON CORONERS' INQUESTS.

The following letter has been addressed to us by a medical gentleman of Chudhigh:-

1,34

1836. teem. The medical man in this case, was appointed to afford practice for the young aspirant to medical honours.

Here, then, is an instance of favouritism you, I could not refrain from transcribing and monopoly, in addition to the many that are admitted by the contraction of the property of the proper nors, than, is an instance of favouritym you, I could not retrain from transcribing and monopoly, in addition to the many the organizationited by my decembed partner hundred proofs which you have advanced in and nigadf to the Associated Apothecaries, the poor is often made subservient to pri-different view of the law. (See Answer 3rd.) vate interests. And now for the Board of So do you respecting the compulsion so attend a Coroner's summons. (See Answer The Poor-law Amendment Act came late 1st.) After the receipt of this opinion we operation here last year; guardians were communicated it to our musical brethren chosen, and, among the rest was chosen the and the neighbouring Coroners; and we great man, - the "ruling passion" being suggested to the Coroners that they should strong. The election terminated on Satur- require the parish officers to provide a medical day evening; the Board of Guardians met man for the inquest, which has been acted on, on the following morning at ten o'clock, and by which we have had our fees,—of Mr. "Ruler" was nominated Vice, and that course, making our agreement with the medical man the it remembered, his son's remuneration, I would suggest that it be paid master) should be appointed to the district. by the relieving officer of the Voor-law No opposition being offered the motion was Union, by order from the Coroner, i. e., in scheme; no one but those who were inte- able people there should be some power rested had the most remote bled that the given to the Coroner, -- what, or by what

There is another point to be considered, no time to arrange or to propose a plan to the certificate given by the Cotoner for "ensure a tolerably minute division of me- herial. I consider that, in future, if the dical labour." Hence, seven parishes are Bill for the relief of the Discenters should under the care of one medical man, whilst pass, the certificate for harial should be ad-1, who live in the centre of them, am ex- dressed to the Registrar of Births, Deaths, cluded from deriving any advantage from and Marriages, who could send it to the offiattending the poor, either in the way of ex- ciating minister of the sect to which the perience and improvement, or in a pecu-discussed belonged, or to the elergyman of niary point of view. I have entered into the parish. If there should be any inquiries there details, in order to show the injustice required by you to be made relating to this which arises out of the present system, and bill in these parts, I should be happy to lead the necessity of adopting the plan suggested my assistance. I remain, Sir, yours re-

J. G. CROKIR.

To Thos. Wakley, Esq., M.P.

General Committee held at the Crown-and-Aacher Inn, June 5, 1820, Jas. Parkinson, Esq in the Chair.

Resolved, - That the opinion of the Common Sergean: Knowlys be obtained on the general question of the law, with respect to the remuneration of medical men when called upon professionally to investigate judicial cases before a Coroner.

Besided,-That Edmond Bacot, Fsq. be requested to draw up a case, grounded upon the foregoing resolution, and lay it before the Common Sergeant, and that the Secretary he desired to wait upon him, with Messrs Croker and Langley's letter for the

"Case.—On the 18th of January, 1820, Messes, Cropper and the of Bovey Teacey, Challetgh, Devos was summoned by the Caroner of the county to examine edy of a pauper, and to give evidence

the party. 1820, they west Coroner to attend for a similar purpose.

"On both these occasions the Coroner gave them a certificate of their attendance. with an order to the churchwardens and overseers of the parish to which the pauper belonged, to pay the fee which has been usual on such occasions, of one guinea for each juquest, but the parish officers have refused payment of the fee. The Coroner says, that it is always usual and customary for the parish to pay these fees in case of paupers, but he has no authority to enforce the payment. Under these circumstances your opinion is requested, -

"First. Whether a medical man (not being apothecary or surgeon to the parish to which a deceased pauper belongs) is compelled to attend the Coroner on his summons; and to examine the body of any dereased person, either a pauper or otherwise, and to give evidence as to the cause of the

Jeath of such person?

" Serond. 🔏 a medical man is compelled to attend on the Coroner's summons, is he entitled to charge for his trouble and loss of time, and who is liable to pay such charge?

" Third. Has the Coroner power to give un order to the churchwardens and overseers to pay a fee to a medical man for attending an inquest upon the body of a pauper of this parish, in consequence of the coroner's summons, and for examining the body of such paoper; and if so, by what means can such order be enforced?

" Fourth. Is there any and what difference in the rights of a medical man who is surgeon to the parish to which the panper

belongs:

"Fifth. What measures would you advise! the parties to pursue, under the circum-stances above stand?"

ANSWED

"1st. I am of opinion that every man, medical or not medical, is compellable to obey the Coroner's summons in his legitimate inquiry respecting the death of a sub-

"2nd. By the common law of the land nobody had the power to demand any remuneration for his trouble or expense in attending to give evidence in any criminal case. The 25th Geo. 2 partly gave the court power to order the expenses of the prosecution; that power was enlarged by 27 Geo. 2, and finally extended still further by 8th Geo. 3. In this case a medical man no power to make a charge for his

trouble and loss of time, nor is anybody liable to no consider the new legal authority to make a legal authority and legal authority authority and legal authority and legal authority and legal authority authority and legal authority and legal authority authority and legal authority authority and legal authority a and overseers of the parish to remunerate the medical gentleman who attends

dence according to the Coroner's Coroner, I believe, to make out an order, and for the parish officers to act upon it, but it is certainly not binding upon them, though it would be disgraceful and indecent to withhold from the medical attendant a fair and reasonable fcc upon so important an occasion.

"4th. I consider this query answered by what I have said on the second query.

"5th. There are no legal compulsory means of obtaining payment. The only way I could suggest, to obtain payment, would be by stating the case to a vestry meeting, and putting con-honour and humanity.
"Newnan Knowlys. and putting the matter to their sense of

"Lincoln's Inn-fields,

June 10, 1820."

* Our opinion periocity coincides with that of the late Mr. Knowlys. What we stated in reply to Mr. JERVIS in the House of Commons, was this, - That the coroner had the power to compel the attendance of a medical witness, but that he had no power to make the witness institute a post-mortem examination, or to enforce payment against the churchwardens or overseers, or any other persons, for the performance of that duty when it was executed.

MEDICAL WITNESSES BILL.

A PETITION, of which the following is a copy, was presented to the House by Lord Henniker, a few days ago. In attaching signatures to the petition, the feeling as to the justice of the claim appeared to be equally strong with all the gentlemen who signed it. Indeed, Mr. Denham, to whose praiseworthy industry it is due, informs us that it seemed only to be required that some one person should act first in the matter, to induce them unanimously to lend their aid.

To the Honourable THE COMMONS of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

The Petition of the undersigned practitioners of medicine and surgery, resident in the stated towns and villages in the county of Suffolk, humbly showeth,

That your petitioners are fully convinced that in a great majority of cases of sudden and violent death, it is utterly impossible for a coroner's jury to arrive at a right conclusion as to the cause of that death, without the testimony of a medical witness, founded on a post-morten examination of the body.

PROCEEDINGS AGAINMY

surgeon not unfrequently attends a surgeon not unfrequently attends a surgeon not That considerable danger to the such post-morten examination, which re-quires great skill and anatomical and pathological knowledge, not to be acquired without considerable study and expense, and often not without risk of life, to remor it efficient for the purposes of evidence.

That your petitioners are liable to imprisonment if they neglect to oney the minmons of the Coroner to give evidence at the inquest; and that, in many instances, several hours are occupied by the Coroner in prosecuting the inquiry, during which the surgeon is often obliged to wait, at very great inconvenience to himselt.

That the Coroner possesses no authority to order remuneration to be given to medical witnesses for the heavy sacrifices which

they are thus obliged to make.

Your petitioners, therefore, humbly solicit your honourable House to take this their petition into your earnest consideration; and to award them such fair remuneration for their services as shall seem to your

honourable House to be sufficient and just. And your petitioners, as in duty bound,

will ever pray, &c .:-

FREE HOSPITAL

GREVILLE-STREET, HATTON-GARDEN.

THE ninth annual meeting of Governors was held at the Gray's Inn Cuffee House, on the 23rd of February, and again, by adjournment, on the 1st of March. About 300 attended the first meeting, and 200 at the second. At the preceding quarterly general meeting, notices of motions were given for the removal of Mr. Heatsch the resident the removal of Mr. Hentsch the resident Mar Tonn Strvans moved a similar response and Mr. A. Tweedic one of the state are respecting Mr. Tweedic, and it was

use those gentlemen had in testimonials in care of gosorrhees, which had been freely advertised with their names, that of the former being dated from the "Free Hosstal." The proposers of the proposition for the removal of Mr. Hentsch and Mr. Tweedie, urged in their notices of motion that "one of the principal objects in instituting the hospital, was to lessen, and if possible to annihilate, the mischievous consequences resulting from diseased persons being deluded by advertising quacks," and that the advertising of the testimonials had materially injured the reputation of the institution. Against Mr. Tweedic they also complained that he had also " without consulting with his medical brethren, administered to the hospital patients under his care, the nostrum.

After the yearly report had been read,

Mr. MARSDEN spoke to the following effect :- He regretted seriously the occasion of so large an attendance of the subscribers, but one of the chief objects of the charity had been violated, and he felt it his duty to call attention to the fact, declaring that he was actuated by no private or personal motive in the step. Since the publication of the "testimonials," several subscribers had seceded from the charity, believing that the officers were encouraging quickery, and a representation of the fact was made to Mr. Hentsch and Mr. Tweedie, and a sort of promise obtained from them that the cause of complaint should be removed, but without realization. Therefore he . Mr. M. felt compelled either to retire from the institution altogether, or take the opinion of the governors as to the propriety of removing the testimonialists, and thus sever the name of the hospital from the objectionable advertisements. If he Mr. M. had erred in this course, the meeting would fearles ly say so, and censure his conduct. Mr. M. then proposed a resolution for the removal of Mr. Hentsch, which was seconded by Mr. WATSON.

Mr. HENTSCH rose, and read his reply. When he gave the testimonial, he did not know that it would be published. The medicine was not a nostrum, but a new form of an old and well-known drag. He had requested the withdrawal of his testimonial, but the advertiser of the medicine refused to withhold it. He Mr. H. believed that personal motives alone induced this proceeding against him. He had faithfully discharged his duty, and now deing ed justice at the hands of the meeting.

Mr. Manney said that it is were not a nontrue, and Mr. If any would make known the composition of the M.) would at once withfluw the restraint.

seconded by Mr. MERK. GALL

gentlemen spoke mulgation of quack me that Mr. Tweedie had sided the purpose of a quack on the present occasion, especially as the professional talents and character of Mr. Tweedie were of a high quality, on which account he (Mr. G.) exerted his influence to procure for him the office he held in this institution. However painful, thereforce the circumstances were to him (Mr. G. , he did not hesitate to second the resolution.

Mr. Tweene, with much eloquence, defended his position as surgeon, on grounds similar to those urged by Mr. Hentsch, and read a copy of a letter which he had addressed to the Council of the College of Surgeons, in answer to which, the sceretary of the College had replied, that the Council " could not believe that the governors of any public institution would remove any medical officer for having tried a new method of administering an old and wellknown medicine."

A Governou observed, that it was not for thet, but for having used and recommended a secret postrum, that these proceedings were instituted against Mr. Twee-

Mr. Tweepin concluded by stating that he would not be alarmed into the act of resigning, either by observing the number of governors present, or by a knowledge of their opinions. The merit, or the demerit of his dismissal, must rest on their own shoulders.

Mr. Branshy Coopen, a newly-made governor, said, that he had himself used the medicine, and after applications from the proprietor on five successive days, he had given him his opinion in writing, rather than be troubled again on the subject, but had be known that the certificate would have been published, he would have lost his right hand somer than give it. It was, however, not a nostrum, but a preparation, which, if he were to explain, would not be thren. understood by any one present. (Cries of " explain," " explain."; He doclined explaining. Was he, or his friend Mr. Green, or Mr. Tweedie, to be publicly called to account by Mr. Marsden? Who was Mr. Marsden? He had never heard even his name until recently, and he believed that wif there was any quackery at all in the business, it emanated from the party who had brought the matter forward. He (Mr. C.) had the honour of holding one of the first i appointments in one of the first institutions

in this kingdom, and he (mapping his fingers) fared neither for this charity, nor for the opinion of its governors, and sooner than subsect the such treatment, by Here the seasons were so opposed to the impetuosity and the expressions of the from Tuesdays to the second and fourth Mia speaker, that he was obliged to see the

descriptions are followed his final

Mr. H. WAITHMAN defended the conduct of Messry. Hentsch and Tweedie, and moved an amendment upon the motion against Mr. Hentsch.

Aiderman HARMER said, that as the " testimonials" continued to be published, it would be impossible for the writers to be allowed to retain their offices in the institution, without upholding connivance at a disgraceful system of quackery in physic. culogized the professional character of Mr. Tweedie, and should be ready to help that gentleman to any other appointment. He was satisfied that no personal pique occasioned the introduction of these motions.

Dr. Uwins (a physician to the institution) defended the testimonialists, and stated that he had that very morning recommended the secret medicine to one of his near relatives. He would resign if Mr. Tweedie were re-

moved.

Dr. RYAN (also one of the physiciaus) and Mr. Lucas both defended the conduct of Mr. Tweedie, and concluded by stating, that they would resign if the resolution against Mr. Tweedie was carried.

Mr. GREVILLE JONES, another of the medical officers, paid very carnest compliments to the integrity and talents of Mr. Tweedie; but he declared against the quack testinonial system, whether the medicine were good or had; for the public were not competent judges of diseases and their modifications. There was extreme imprudence in Mr. Tweedie's allowing the possibility of his name being connected with such a system, and the improdence on the part of the surgeons of St. Thomas's and Gny's Hospitals was still less excusable. Whichever way the question terminated, the discussion would teach many eminent men not to let their good-nature or personal attachments betray them into supporting a system of plunder, frequently tatal to mucco life, and always injurious to their professional bre-

After several other speeches pro and con, the meeting divided. On the motion against Mr. Hentsch, the show of hands was .- For the motion, 200 and odd. Against it 61.

On the motion (on the second day of meeting) against Mr. Tweedie, the show of hands was declared to be 5 to 1 for the motion.

The usual business of the annual meeting was then gone through, and the meeting dissolved.

In consequence of the days of meeting of the Medica-Batanical Society coinciding with those of the Medica-Chirurgical, it has been determined by the Committee to alter the evenings of the Botanical Society's meetings Wednesdays of the month.

MEDICO-CHIRURGICAL SOCIETY

ATROPHY OF THE VALVES OF THE MEART.

THE following is an abstract of a paper. read at the above Society, on the 23rd of Feb. and the 8th of March, entitled, " Remarks on Two Forms of Atrophy of the Heart's Valves, which interfere with their Function; founded on Cases, by Dr. P. N. KINGSTON, Physician to the St. George's and St. James's Dispensary ."-

The first of these lesions, which, says the author, has hitherto been altogether overlooked by pathologists, has been observed by Dr. Kingston in numerous cases, in eight of which it had proceeded to a considerable extent. It was defined, " A simple shortening of the heart's mitral or tricuspid valve, without any diminution of its natural thinness, pliancy, and transparency, the orifice to which it belongs having at least the ordinary caliber."

The second of these lesions (to which the acrtic and the pulmonary, as well as the auriculo-ventricular valves are liable) is nearly allied to the preceding in its nature and effects: - " When so altered, the continuity of the valves is interrupted by apertures, sometimes of a large size, and sometimes so numerous as to reduce the structure to a mere network, while the remainder of the valve is in a state of attenuation, which is here and there often extreme, especially towards the edges of the apertures." In five of the cases, a considerable portion of the valve had been thus affected. The only preceding writer who has at all noticed this appearance, is Laennec, who has merely glanced at it. These lesions are not very rare, but they are very liable to be passed unnoticed, unless the attention has once been directed to them.

A valve which has become shortened or cribriform, is, of course, incompetent to close completely the orifice to which it belongs, and hence permits that regurgitation which it was placed to prevent. From this disablement of the valve arises a strong tendency to dilatation or hypertrophy of those parts of the heart which are posterior to the valve affected, to pulpitation, to venous congestions, to anasarca, and to effusion into the rerous cavities, and, where the mitral valve is defective, to dyspnœa and cough, also to pulmonary congestion and inflammation, and to some of those symptoms which are apt to arise from a deficient and irregular supply of arterial blood to the head, and the remote parts of the body. A morbid "bruit" may, in some cases at least, be perceived with the stethoscope. the tricuspid valve is affected, there is distention, and sometimes pulsation, of the external jugular veins. Where the mitral

cted, the pulse is small and parison with the heart's imequal.

By a reference to these symptoms, and to the circumstances out of which the complaint arose, it may generally be ascertained whether or not there is valvular disease. The discrimination of these from the other valvular diseases is a point of great nicety, on which the author stated that he was not

as yet fully prepared to speak.

These defects may now and then be congenital, but in all the present instances they bad evidently been produced, long subscquently to birth, by those species of absorption which are unattended with suppuration, a conclusion which coincides Meckel's opinion respecting similar defects of the valves of the veins. From the histories of the cases, and from numerous analogies, Dr. Kingston infers that their most frequent causes were either, 1st, debility of the valve's nutritive powers, combined with undue force of the blood's impulse (from hypertrophy of the ventricle, over-exertion, &c.); or, 2ndly, so great a degree of local debility (often consequent on gouty or rheumatic action), as to render the valve liable to be absorbed under the pressure to which it is naturally subjected.

The author concluded by pointing out the errors which may have arisen from an oversight of these lesions at post-mortem examinations,-the practical advantage of detecting them during life (even so far as to perceive that there is some valvular defect obstructing the circulation),-the means by which the frequency and extent of the lesions may be diminished, - and the circumstances under which it may be hoped, either that the valvular structure may be restored to its original dimensions, or that the corresponding crifice and cavities may gradually diminish in caliber, so as to become adapted to the altered size of the valve.

THE LANCET.

London, Saturday, March 12, 1836.

ACTIVE exertion under oppression and the infliction of injury, becomes the duty of intelligent men. We expected that the medical practitioners of this empire, when they found that there was a change of obtaining from the Legislature is produced against the annoyances to which they trave been subjected at Coroners' inquests, would come

The second of the second

forward and energetically suppos however humble Commons. The events of the last fortnight the alds of justice if they cannot be dis-

There are a few stupid and narrow-minded writers, we perecive, who invist that the Mentovi, Witnesses Brut refers merely to a medical question, and they discuss with characteristic sagacity, what they are pleased to denominate "its merits." In rendering this important service to the public, it is satisfactory to observe that their efforts in the way of reasoning are admirably proportioned to their ignorance of the subject in his character as an ordinary member of under investigation. Why do not the con- society, or as a casual observer of the cirjurors ask themselves this question-" Of cumstances which produced death, and he " what use is the Coroner's inquest, on really "important occasions, in the absence of "competent medical witnesses?" If they had sense enough to answer this simple fact? In not one case out of a hundred is question, the offusions of their brains might he summoned as a private individual,—as a that as the Coroner's court is now conducted, learned and most useful profession; and in the chief that his jurymen are as his professional character, therefore, is he and charistens. In cases of desta from coroner and his jury. This distinction is so

malegravie, from mineral poison, from Pills," from dexterously-adshould advocate their cause in the House of ministered vegetable poison, where are have proved that we did not make a wrong covered in the experience of the patholoestimate on this subject. The petitions from gist, and the researches of the chemist? medical practitioners continue to be pre- Better, at once, as we have frequently sented to the House daily, all praying that stated, abolish the Coroner's court altogemedical witnesses at coroners' inquests, ther, than continue to withhold from medimay receive some compensation for such cal men a just reward for the services which services as those which they have hither- they execute in that court, and to allow nonto almost invariably been required to medical functionaries to preside over its bestow gratuitously, in aid of the main- proceedings. At many of the inquests tenance of the cause of public justice in which have lately been held, the powers of After the Medical Wir- this institution, when they are properly ex-NESSES BILL has left the Commons, we will creised, must have forcibly attracted public furnish our readers with the names of the attention, and have illustrated what has so places whence petitions may reach or have often been stated in the pages of this Jourreached Parliament, when a statement will just, with reference to the shield which, be exhibited which will prove to the mem under many trying circumstances, it prehers of the profession resident in this metro- sents to the community. The Bill, therepolis, how ably and faithfully the surgeons fore, which is now before Parliament, is only of England and Wales can discharge their one step towards improvement in this imdaties to the interests of that profession portant branch of our judicature, but it which has the good fortune to claim them as must, necessarily, lead to many others of a satisfactory character.

It is alleged, we find, by Mr. CRIPPS, and other gentlemen who consider that medical witnesses ought not to be paid for their attendance at coroners' inquisitions, that the proposed Bill introduces a distinction, with reference to one class of persons, which may with propriety be claimed by the members of all other trades and professions. What folly! Take the medical practitioner is content to stand in the court upon an equality with every other individual who is similarly circumstanced. But what is the rminate. It ought never to be forgotten, casual spectator, -but as a member of a became the hole of quacks called upon to act for the edification of the

evident, so striking, so convinci equivocal, as an indication of the peculis duties which the professional witness has to execute, that all that remains on the subject, which admits of a patient notice or consideration, is comprised in an answer to the question,-What is an adequate remuneration for the labours which a medical witness is required to discharge? Although we cannot hope that an answer, which shall be fully satisfactory to this question, will be acted upon in the House of Commons, yet, from the manner in which the medical petitions are received in that House, and from the liberal spirit with which the motives for introducing the MEDICAL WITNESSES BILL WAS regarded on both sides of the House, it is hoped and expected that an award will be made somewhat approaching to the importance and the justice of the demand. In reality, the question which the Commons are now to determine is, whether the Coroner's Court shall henceforth be a useless institution, and a profitless drain on the county rates. or whether the public shall find that it is a source of protection against the merciles: impositions of quacks and other criminals.

Never have quacks, quackish doctrines, and quack medicines, exercised a greater influence over the minds and bodies of the people of this country, than they exert at the present epoch. Are such evils to be patiently endured by the scientific members of a noble profession? Common sense, common honesty, and philosophic attainments, alike forbid so scandalous and disgraceful an imputation. The source of the existing evil is to be found in the odious, the exclusive conduct of our rotten and contenptible medical corporations. The College of Physicians, with an ample store of vain conceit and malignity, has done itbest to be mischievous; but the members of that corporation having always been limited, its quackish exclusiveness has been

re for i for the amount of positive injury which it has inflicted upon the community. But the results of the conduct of the College of Surgeous, although that conduct has been somewhat similar, have outstripped all comparison with those of the establishment in Pall-Mall East A precious game have these two institutions been playing during the last six-andthirty years, and it is scarcely surprising to observe that the murderous quacks are sought after by the community, to the exclusion and rejection, in case of need, of licensed practitioners in medicine. The College of Physicians commenced their career by passing a law of exclusion against surgeons. Practitioners of surgery were not deemed worthy of admission into their body. The College of Surgeons, admiring this prudent and general system of excinsion, went a step farther, and a Council, consisting of the self-elected pures of our hospitals, resolved that no surgeon in general practice, that is, that no general practitioner, should be admitted to a seat in the Council. Thus the public were told by the two English Colleges, which had been appointed by royal charter to protect the interests of the profession, and, above all, the health of the community, that surgeons who were engaged in executing the duties of medical practice in all the departments of the profession, were not deemed by the heads of their own colleges qualified to be received on equal terms with themselves, into those national establishments. The Colleges, in short, were industriously employed in disgracing the great majority of the profession, and the results are now before us. Quackery is rampant, and the poison of quack medicines is spreading desolation around, with a virulence and a fatality not exceeded, probably, by that of the plague or the cholera. We are not to draw our inferences of its offects from our three, or even from they inquestry horas even from a thousand, though as many were to be held

949

in a single year. We are to to the fatal consect

inevitably happen from plates a reliance on The powers of a supposed curative agent in ALL diseases. We ask, -In the sands of instances where the results are fatal, will the relatives and friends - the secret abettors of quackery-at once, by acknowledging their delusion and folly, make a confession of their guilt? Nothing can be more absurd than to entertain such a belief. The unfounded, the monstrous reliance which is placed by an uninformed public on the powers of quack medicines, must, from the natural course of things, be followed by the most frightful catastrophes, and it is equally true that the confessions of error will be of small amount. It is not easy to obtain an acknowledgment of the imperfect operations of the judgment, because pride is ever interposing to shield the mind from self-exposure. Every experienced quack is well versed in these weaknesses of our nature, and shapes his course and frames his stratagems accordingly. The ignorance of the community is the soil which they cultivate, and the press is the machine which is set in motion for securing to them a full harvest for their labours.

the operations of these infamous maranders? The indications are simple and striking. The might of the press must be turned against its mercenary abusers, and the ignorance of the people on medical subjects, must be made to give place to rational views of the science, before a hope can be entertained that the existing pestilence will experience shock or check in its reckless career. Without the aid of the press, quacks would be as powerless as other impostors, and even with the use of that engine, were it not for the undiscriminating ignorance of public, it could not be rendered available to their neferious purposes.

fee, that the Government Fearing, t will take diate steps for exterminating quack medicines, and sending their interesting girl," says the reporter of The

ors and proprietors to the helks, we upon the members of the medical profession in England to take the matter seriously, and at once, into THEIR OWN HANDS. They should instantly institute,-by a general subscription, and a combination among themselves, -an

ANTI-MEDICAL QUACKERY SOCIETY.

having its Central Board, with an efficient paid secretary, constantly sitting in the metropolis, composed of the legally-qualified members of the profession, without distinction. Its connections would necessarily be ramified throughout the entire kingdom, and the whole powers and energies of the society, thus organized, should be concentrated on two objects, one present, the other remote. The first, that of apprizing the public in every town and village of the empire, through the medium of anti-quackery tracts, to be supplied from the Central Board, of the murderous results of taking quack medicines; and, remotely, to obtain, by a well-organized process of petitions, the total suppression of the sale of stamped, patent, and secret medicines, through an act of intervention of the Legislature.

The expense of carrying this scheme into What, then, is to be done to counteract execution would require only a very small contribution from each legally-qualified medical practitioner, and the advantages to be obtained by its operation would, we are convinced, be almost concomitant with the first hour of its institution. At any rate, it is a subject which we believe will be found, on reflection, to merit the deliberate attention of the profession.

> Having thus put forth the suggestion, we shall in the next LANCET, take a more extensive view of the question, and endeavour to illustrate what would be the advantages of the acts of a Society such as we have now proposed.

Ar the Spring Assizes held at Winchester on Friday, March 4th, Jane Melchear, " an

Times, " was indicted for the stilled with of her nest-born female child, at South ton, on the 19th of September last .- Mr. Saunders conducted the case on the part of the prosecution ; Mr. Missing the the prisoner." Several witnesses were amunised for the prosecution, and, after a trial of and as much as possible from external seven hours, the jury returned a verifict of moisture, they should be laid in thin layers "Not gullty of the nourder," but "gullty of on willow baskets, stripped of the bark, the concealment." and she was sentenced to They must be placed in a room from which three months imprisonment. At the close of the report, the writer of the statement adds the following observations :-

"One thing is worthy of remark. The surgeon who was first called in, and who examined the person of the prisoner, and the child, afterwards presided as coroner at the inquest sitting on the body of the child, when the jury returned a verdict of 'wilful murder, and he eventually gave evidence ing the leaves. against her on the trial, having previously acted as judge in the case. Without, in the slightest degree, casting any imputation on this gentleman, we cannot but consider this as a state of things which ought not to exist, and it is a very strong argument against the appointment of medical coroners.

The "argument" which the writer,-a barrister, most probably, -suggests in this case, as showing the impropriety of appointing medical men to fill the office of coroner, is exactly such an one as we should expect to hear, not from an intelligent reasoner, but from a parchment-headed scribbler. to institute such a protection, if it be a wise the 1st instant, of your intention to introbe necessary? And when it was deemed necessary, for the ends of public justice, that an inquest should be held, then he was obin his power to appoint a deputy. No imcast upon the coroner, for acting as he did at the inquest, and at the trial in question. That the law is loose, and most imperfect with regard to the office of coroner, generally, we willingly confess; but, before it is mended, it must find other correctors than I am, Sir, in there, yourse the sapient critic of The Times.

At the list meet-Society, Dr. Siggible method of drying and preparing the leaves of commun maculatum for medicinal use. The leaves being in a high state of preserall light is excluded, and then submitted for three or four hours to a heat of a little below 212° of temperature. Having been then turned, they should be exposed to the same heat for about eight hours. They are then crumbled by the hand, with great fa-cility, into a fine powder. Dr. Sigmond showed a good specimen of the powder prepared in this way. Dr. S. considered that the autumnal season was the best for gather-

BATH PETTION.

IMPURE CASTON OIL - Dr. Sigmond also cautioned the profession against a fraud which had been extensively practised by a company who had invented a process, by which rancid and ineffective castor oil could be made apparently sweet and good. It is, however, perfectly useless, and possesses no purgative power. Great quantities have been disposed of, and he thought well that the system should be exposed.

MEDICAL WITNESSES' PETITIONS.

To the Editor of THE LANCET.

Sin: The members of the medical pro-Did it not occur to him that medical coro- fession must be much gratified at the manners might not be engaged in medical practurer in which the announcement was retice, and that it is in the power of the law ceived by the House, on Tuesday evening, one? But, as a lawyer, he ought to have duce a Bill for granting remuneration to known that the medical coroner in the case medical witnesses, for their attendance at in question had no alternative. Having at- duced at the monthly meeting of the meditended the prisoner in the course of his cal society of this city, on Friday evening practice, how could be conjecture, before last, and a committee was appointed for the the result was known, that an inquest would purpose of drawing up petitions to both Houses of Parliament, which they have done, and they will probably be signed by all the medical men in the city and neighbourhood. Enclosed is a copy for publicaliged to act as coroner, because it was not tion in your widely circulated journal, should you consider that its appearance would exputation whatever, therefore, can be justly cite others to follow our example. The favourable reception of the motion for leave to bring in the Bill, does not justify us, in my opinion, in relying upon the first success of the Bill, but it becomes the daty of ever member of the profession instantly to enbody his sentiments in petition, and forward it to the only state for redress.

3, Wew King-st., Bath, March 9, 1836.

In another p rt of this We have in our we have insered copy and that we irnst will serve the same purpose as would the insertion of the petition forwarded by Mr. King, and many others with the same inportant prayer, which we have within the ast few days received from medical gentleneu in different parts of the kingdom.

LATE ADDRESS TO APOTHECARIES, HALL

To the Editor of THE LANCET.

Sin: I was truly astonished to learn how chicken-hearted the students of the London University had become when they sent their address to the Hall. I thought they posressed more courage and more knowledge than to fear the Rhubarbians. How are the vaunted fallen! How have the students of my alma mater degenerated! In days gone by, no document would have been signed and forwarded to the Blackfriars establishment with any evidences of fear or want of favour. The students would have had more confidence in their abilities and acquirements, than to how and pray for mercy before Ridont and Co.

1 perceive in the list some names of 1832men. M**rh**d, W*k***ld, and others, I blush for you. Among others I see J. D*r-"ne". Are you afraid, too? "Tell it not in Gath." I am, Sir, yours.

METROPOLITAN INFIRMARY FOR CHILDREN.

Broud street, Golden square.

MEASLES FOLLOWING CROUP.

George Coores, aged 5, a remarkably fine and robust boy, was entered as a patient under Dr. Tweeddalk, on Monday the 29th of February last. The little patient was labouring under the frequent, dry, hoarse cough which is peculiar to croup. His skin was hot and dry; the face flushed; the eyes suffused; the tongue white and farred; pulse 130, full; bowels costive; he complains of headache and lassitude. His mother states that on putting him to hed on Saturday evening she noticed that he had a ard dry cough; he was very feverish all day on Sanday, and in the evening she procured some patients for him, which made wards divided. Two other large flans were lain very that feeches were applied immediate. The threat made, each forming nearly a semicircle; the immediate. The threat made threat prains one directed upwards towards the side of calous, the two powdered scammony, the neck, the other downwards. All the of calouss, the five of powdered scammony, the neck, the other downwards. All the were given every two hours small the massles of the dorsum of the scapula were

hi were well purged, and a tablespoond of a mixture containing liquor antim. tart., and oxymel of squills, of each five drachms, and four ounces of saline mixture.

were endered every two hours.

Figure 7. The leeches have bled freely;
the lower have been well opened; he has vomited, several times, a quantity of thick mucus, with small portions of fibrine. Two grains of calomel and three of James's powder, were ordered to be given every four hours. The mixture to be continued. To be put into a warm-bath up to the hips.

March 1. Still feverish; pulse 110, and small; cough much relieved. The surface is covered with the eruption of measles. Three grains of calomel and six of scammony powder, ordered to be taken directly. The other medicine to be confinmed.

2nd. Fever much shated; bowels do not keep open without medicine; pulse 100, small; cough still troublesome, though there is not so much expectoration; the eruption is developed more fully; he is able to sit up in bed; a blister was applied to the chest, and a purgative was given night and morning. The powders and mixture dis-continued. He continued to improve, and is now convalescent.

This is the second case, in the infirmary, of croup followed by measles, terminating favourably under the same plan of treatment. The first patient was a healthy boy, eight years of age, who was bled from the arm, and had leeches to the throat.

ST. BARTHOLOMEW'S HOSPITAL.

TUMOUR ON THE SCAPULA .- James Jackson was brought into the hospital with a large tumour, occupying the left scapular region, of about the size of two-thirds of a large melon. A tumour of about half that size had been removed, five months previous, from underneath the scapula, by Mr. EARLE, but the disease returned, and increased to the above magnitude, continuing rapidly to enlarge up to the day of the operation. From the condition of the old cicatrix it was by some authorities deemed malignant. The operation was performed by Mr. Skev. The man, after some loss of time occupied in determining his position, was finally placed in the re-cumbent posture on the operating-table, lying nearly on his face. The operation was commenced by an incision, forming a part of a small flap, reflected towards the shoulder, which exposed the spine of the scapula, over the line at which it was afterthen divided, for the purpose of charles the bone in perpendicular line, should be the third distant from the glenoid cavity, towards the base. The spine was divided by a common about thing-saw, the upper portion of the bone by Hey's saw, and the lower fossa was split up with Liston's forceps. The hemorrhage was then considerable, but was arrested by the assistants, each of whom seized one or more vessels. Moreover, the subclavian artery was compressed above the clavicle; an inclaion, nearly fifteen inches in length, was then made along the basis of the bone, but between the spine and the old cicetrix, the whole of which was removed. The tumour was rapidly dissected from the ribs, and removed, and the bleeding arteries were tied. A small portion of the disease was found adhering to the neck of the bone, close to the shoulder-joint, which was dissected off with a silver knife.

On the conclusion of a consultation which was then held on the case, the patient was recommended to undergo the removal of the whole upper extremity. To this he would not consent, and Mr. S. removed the remaining part of the muscle, close to its insertion into the hunerus. The wound was united by sutures, and the patient retired, much exhausted from the loss of blood, having been on the table nearly threequarters of an hour, of which period the removal of the tumour occupied but twelve minutes.

Secondary hemorrhage occurred within a few hours, and on securing the vessels the wound was dressed with lint. Thirty-five drops of laudanum were given to him. He remained quiet throughout the night, and on the following day he took repeatedly small quantities of beef-tea. The operation was performed on the 22nd of February. Up to the present time he has had no had symptom : the wound is covered with healthy granulations. The tumour was composed of the same structure as that for which the former operation was performed, viz. albuminous sarcoma. More than half the scapula was entirely absorbed. The tumour was moveable on the ribs, which were perfectly bealthy.

NORTH-LONDON HOSPITAL

SCIERHUS OF THE BREAST. - OPERA-TION .- Mary Welch, aged 47, a milkwoman, was admitted on the 16th of February under the care of Mr. Coopen, on account of indurated enlargement of the right breast, of six months' duration, consequent upon a severe blow received about that period. The swelling became gradually larger, and is now about the size of a man's fist; the nipple is depressed; the tumour is hard, craggy, very firm, and very moveable. The axillary glands do not appear to be affected. She

not discoloused menstrusion is regular, but more acenty than it has previously been-She has horse nine children. Mr. Cooper. recommended the removal of the tuniour: to this the consented, and on the 18th he proceeded to operate. He first made two elliptical incisions, and dissected from below upwards, first on one side and then on the other. Two arteries were cut in the first incision upon the inner side. The fingers of an assistant instantly suppressed the hemorrhage until the whole mass was removed. About five vessels were tied, the largest in the substance of the pectoralis The two integuniental major. vessels. which bled very smartly at first, had now contracted within the subcutaneous adinose tissue, and appeared much smaller than at There was another vessel tied, at the upper angle of the wound. A small portion of scirrhous tissue having been left behind, it was removed. The sides of the incision were brought together with several broad strips of adhesive plaster, the ligatures hanging out in the interspaces; a compress of wet lint was applied over the plaster, and then a broad piece of cloth was pinned around the chest. Her arm was placed in a sling, and she was sent to bed. Mr. Coo-PER prefers the broad piece of linen to a bandage, as, in case of secondary hemorrhage, it is easily tightened without requiring to be first removed. This plan he has known to succeed in several cases where secondary hemorrhage has occurred. Indeed, according to his experience, secondary hemor-rhage is more frequent after this operation than almost any other. In the evening the patient took half a grain of the muriate of morphia, and was then pretty easy.

DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVER-SITY OF PARIS.

By M. ANDRAL.

Physician in Chief to the Hopital de la Pitie, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Medecine of Paris.

LECTURE XVI.

RAMOLLISSEMENT OF THE NERVOUS CENTRES.

(Continued from p. 927.)

GENTLEMEN, -Let us now pass to ramollissement affecting other parts of the brain than the cerebral hemispheres. The first which naturally present themselves for examination are.

The Corpus Callosum, the Septum Lucidum, and the Fornix. We have already described the anatomical

characters of the lesion when situated in those parts, and have now merely to occupy ourselves with the functional derangements to which it may give rise. We shall only softened, we generally find the ramollissemore issement is, then, nothing more than a fornix. constituent element of the disease so generally known with the sease of "acute hydrocaphalus of "disease of cannot now enter into any american of "disease form of ramollisectment; it is foreign to the ques- related in the letters of M. LALLEMAND OR tion which now occupies us, and however diseases of the brain and nerves. Now what

interesting in itself, it would lead us too far from the principal subject of our study. We must, therefore, confine ourselves, for the present, to cases in which Ramollissement exists as a Single Lesion, unaccompanied by any effusion of fluid into the ventricular cavities, which cases are excessively rare, and will not, I fear, permit the deduction of any general principles. The ramollissement now spoken of is remarkable in this respect, that it is rarely accompanied with a red coloration of the nervous pulp; on the contrary, the softened cerebral substance is white, of a dull pale colour, and we seldom or never find any trace of injection in the vessels. ABERCROMBIE gives one case of this kind; but we may establish it as a general rule, that red softening of the medullary central parts of the brain is a lesion excessively rare. It may attack all the three parts mentioned a while ago, or only one of them. Ramollissement of the corpus callosum is the most rare of the three. Softening of the septum lucidum alone is also a lesion very sektom observed in the dead body. In the considerations we have to lay before you on this part of our subject, we find ourselves compelled, contrary to custom, to depend alone on the history of particular facts, for the records of the science do not furnish a sufficient number of examples of ramollissement affecting the white central parts, to enable us to draw a general picture of this lesion. Were we to launch out into general reflections, and attempt to describe the form under an enadd on the present occasion, that, when semble of symptoms, we should only run the chance of deceiving and leading you astray. ment accompanied by another lesion, viz. for we again repeat, the records of medicine effusion of a serous fluid into the cavities of do not afford a sufficient number of facts for the lateral ventricles; this certainly occurs the deduction of general principles. We in a great majority of cases. Whenever ra- shall speak, in the first instance, of ramolmollissement occupies the white central lissement when confined to any one part parts of the brain, it is very rare not to find alone; we shall then consider it when at the same time a greater or less quantity affecting at one and the same time the cor-af serous effusion in the ventricles. The rapus callosum, the septum lucidum, and the

First, for ramollissement confined to the thin layer of medullary substance called sepcannot now turn lucidum. You will find one example of the kind in M. Rostan's work; a second is

No. 655.

150 8

were the symptoms observed in these two cases? Both patients were affected with headache; one exhibited as a lesion of motility, a paralysis of one side of the body, which gradually became general, and implicated the four limbs together. In M. Rostan's case, we find no mention made of paralysis; the patient was merely agitated by convulsive movements. This, you see, is analogous to what we saw before when treating of ramollissement of the hemispheres. The lesion of motility at one time manifests itself in paralysis, at another in disordered movements. In both of these two cases death arrived in the same manner; the patients fell into a state of coma, from which condition it was impossible to recover them.

Let us now turn to isolated ramollissement of the fernix, or rather of the nervous mass placed above it, the corpus callosum. We do not possess a single case of the latter, nor of the fornix alone; we must, therefore, consider them, when softened, one or other, in conjunction with the septum lucidum. What are the symptoms of ramollissement when these parts are simultaneously softened? One of the principal is headache, which is often very acute and distressing. In one case described by ABERCROMBIE. page 129, the pain in the head is mentioned as being excessively intense, and extending across the forehead from temple to temple. In another case the pain was confined en-tirely to the frontal region. This severe cephalalgia is sometimes the only symptom that exists for a considerable period. After a certain time, the faculty of speech becomes affected; articulation is indistinct and embarrassed, delirium now supervenes, the patient falls into a state of coma, and the disease quickly terminates in death. In one case we find dyplopia mentioned as an accompanying symptom. In the work of M. LALLEMAND, there is no question of lesions of motility; he does not seem to have observed either paralysis or convulsions-at least he does not speak of them in the case he has described.* However, in children, we sometimes observe isolated ramollissement of the fornix giving rise to functional derangement of the moving power; you will find some examples of this kind in the thesis of M. FOURNET sus-

tedness, but the stee published are few, and, a standard and, said, we cannot, without danger of cirror, draw any general consequences from so limited a number of facts.

The examples of ramollissement affecting the three parts together are more numerous, though still rare; you will find two it the work of M. LALLEMAND, already alluder to, which were communicated to him by M. MARTIN-SOLON. M. SENN has also de scribed the same lesion in his Treatise or the Acute Meningitis of Children. In many of these cases we find headache given as one of the first symptoms, but in one only does the author speak of vomiting, a symp tom which so often accompanies in its origin acute inflammation of the cerebral membranes. With respect to the faculty of motion, we may notice a tetanic contraction o the muscles as a frequent symptom; this phenomenon is described as attacking vari ous parts of the body, throwing back the head, and giving to the whole trunk a cadaveric species of stiffness. All these cases terminate in coma, more or less wellmarked, which perseveres to the instant o death. These are the usual phenomena ob served connected with lesions of motility We must not forget to mention one more symptom of this affection, which has been described by M. SENN alone, as A Pheno menon of Sensibility peculiarly characterizing Rangilissement of the Central White Parts This is an exalted sensibility in the in ternments of the trunk. "The patient." says this author (" Researches sur la Menin gite Aigue des Enfans," p. 88 , " cannot sup port the slightest pressure without com plaint, and frequently the pain produced by simple contact is so great, that if we con fine our examination to the abdomen, we might be led to conclude the existence of acute inflammation in the peritoneum of abdominal viscera." It would seem, how ever, that M. SENN has exaggerated the value of this symptom; it certainly docexist in many cases of ramolli-sement, and even of simple meningitis, but it is not suffi cient alone to characterize the former le sion, for it is frequently absent.

We now come to a set of cases in which there exists a wonderful resemblance he tween this ramollissement of the three een tral parts, and effusion of serum into the wentricular cavities, or, Acate Hydrweigha.

M. You will find a good example of this it the work of M. Charpenter, of Valenciennes, on the Natural Treatment of Acut Water in the Brain, p. 43. The subjectifies case was a child cleven years of age who had been ill with cough and pain it the throat for four or the subject who had been ill with cough and pain it the throat for four or the subject who had been ill with cough and pain it the throat for four or the subject who had been ill with cough and pain it the throat for four or the subject which was a subject with the subject of the disease and, on examining the body after death, the powerior part of the formix and corpus cal-

^{*} Either we have taken down the name incorrectly, or M. Andrah has here fallen into an error. In M. Lallemand's Researches on the Brain and its Dependencies, 1, p. 184, we find the case of a woman, forty years of age, who died after a short illness; she was attacked with fever, delirium, and convolving movements; sommolence and contraction of the limbs; the corpus collosum and fornix were transformed into a white pulp; all the other parts of the brain were sound.—Rev. L.

losum were the street without any the symptoms which presented in these 13 change of colour; the corebral substance in cases. In the whole of these cases, except the membranes were intact; the lateral ventricles contained only a few drops of serum, nor was any effusion found at the base of the brain. The symptoms observed in this case were, at the commencement, fever, with pain of the abdomen, and bilious vomiting, which persisted for two or three days; headache then supervened, and on the next day the child fell into a state of coma, acthe muscles on one side of the face. In the evening of the same day the right arm became contracted and stiff, but this phenomenon was not of long continuance; it was replaced by violent contraction of the muscles of the neck, throwing the head backseat of contraction, now became completely paralyzed, both with respect to motion and sensibility, and the patient died in a few any cause to explain the hemiplegia which the brain. Now for attacked the patient shortly before death; the only lesion which existed was softening of the corpus callosum, the septum lucidum. and the posterior part of the fornix, and we do not know that physiologists have attributed the faculty of directing motion to any of those parts. This is all we have to say apropos to ramollissement of the white central parts of the brain. Let us turn to the

Ramollissement of one Lobe of the Cerebellum.

the median lobe, or one of the lateral lobes; we speak of softening confined to the ceresellum alone, and not coexisting with a oftening of the median lobe, we are acquainted with only a single case in the re- ramollissement situated in one of the cereords of medicine, it is that given by bellar lobes, some lesion of motility exists. DANCE, in his " Memoir on Acute Hyase was not attended by any special sympom whatever; the patient died in a state of oma resembling apoplexy; we must, thereore, turn to ramollissement of the lateral bes of the cerebellum.

We do not possess the same number of acts connected with softening of the cereorner lesion is much more rare than the atter. Thus we have been able to collect nly thirteen cases of ramollisement con-ned to one of the lateral lobes of the cere-ellum, nine of the lateral lobes of the late elinm; nine of the belong to marious au-hors, four to myself; you will find the lat-g detailed in the fifth volume of the Cli-

the rest of the brain was perfectly sound; three, we find the intelligence preserved for a greater or less period from the commencement of the malady. In two examples, without having been deranged, the intellectual faculties were dull and slow. In the three exceptional cases just mentioned, the disease commenced, suddenly, by a loss of consciousness, as if the individual was seized with a violent effusion of blood into the cerebral hemispheres. The faculty of speech companied by strahismus, and retraction of also remained intact in all the thirteen cases except two. In the one related by M. Mo-Non, the speech was simply difficult, but the patient was still able to make himself understood. In the other, which belongs to M. LALLEMAND, the power of speaking was completely lost. This is all we have to rewards; the member which before was the mark in connection with lesions of intelligence; they are various, but, as you see, of slight importance, except in those violent cases where it is nearly impossible to dishours. In this observation, we do not find tinguish ramollissement from hemorrhage of

Lexions of Movement.

These are observed infinitely more frequently: thus in our thirteen cases we find twelve in which the motility was more or less modified, and perhaps even in the thirteenth this took place also; at least it is impossible to say that no lesion of motility existed, for the author (M. DANY, "Memoir. de Med. Milit." t. 22, p. 379) merely states that the patient fell into a state of coma, without mentioning whether the limbs Ramollissement may affect here either were paralyzed or not; indeed, the whole history of this case is imperfect; even the nature of the lesion in the cerebellum is too vaguely described. We are, therefore, inimilar affection of the cerebrum; as to duced to lay aside the case given by M. DANY, and conclude that in all cases of

But what constitutes this lesion? What brocephalus" (Archives Generales, Janvier is its nature? Under what form do we ob-830; here the ramollissement occupied serve it? These are questions which we he right half of the superior almond-shaped now proceed to answer. In one case we obe, and extended thence to the correspond- find a constant agitation of the body; the ng part of the mesocophale (pous v.) This limbs were neither contracted nor paralyzed, phenomena so often observed in ramollissement of the cerebral hemispheres. but affected with a convulsive agitation occupying equally the upper and lower extremities on both sides of the body. In the eleven cases which remain we find six accompanied by contraction and stiffness of the limbs; five of which gave rise to para-lysis, either with or without contracture.* We have now to ask

^{*} This enumeration differs slightly from where he describes two cases as attended with convulsive agitation, and ten with be Medicale. Let us take a rapid view of paralysis or contracture. As to the case,

CHOTOL

what I know is going on on every side, I feel a degree of repulsioned at such sub-jects, and would almost willing the the shafts of malevolence, envy, and difficultion, upon you, and to expend their harmlers force on the surrounding elements. I pity the pour creatures who have no other means of obtaining a livelinood. They have not the legitimate instruments of advancement within their reach,-industry and intellect,-and what power.

I have still a few words to say on scalded glottis. There are certain cases of this accident in which the calomel treatment will before the system is made to feel the action of the remedy. There are, then,

Certain Cases in which Bronchotomy must be resorted to

first case, Dr. Marshall Hall, a gentleman further demonstrate the personally quite unknown to me, but for whom I entertain, from his writings, the highest respect, proposed the performance the extent and form of the lesion which it of the same operation in the same cases, and causes, as well as the nature and the order gave one in which it had been employed, of the symptoms which it produces with all unsuccessfully, however; and it is only fair of which I have made you acquainted in to state, that although my case preceded former lectures. (See Lecture in LANCET, the publication of his essay, I cannot have 1834, page 657 the slightest doubt that his proposal originated in his own mind, without any know- that some time ago a child was brought to ledge whatever of what had been done by the Dispensary, cold, comatose, and labourme. There are, therefore, certain cases of ing under excessive dyspnien, the respirascalded glottis in which you must perform bronchotomy, to gain time. But, upon this companied by a loud sonorous tale. On point I have to warn you of a mistake into opening the mouth by force to inspect the operation will seldom be alone sufficient, tity of whey-like pus discharged. and if you trust to it alone, you will often lose your patient. The inflammation excited by the injury will, notwithstanding that relief may be afforded by the operapatient will die, not perhaps so soon as if water. These are interesting facts for you the operation had not been performed, but to know. They enlarge our views of the death will, most probably, follow. Bear, pathology of this injury, and show, that therefore, this important fact in mind, although a child may weather the more

are not called upon to employ doses so large, the throat, although no inflammatory action or to repeat them so often, though I believe may have extended to the lungs or chest;

to urge this quint upon you, at for will not find that any of those person tately spoken of the those persons, and the batch spoken of the operation, of the operation and the use in these cases, have spoken of the necessity of employing at the same time, the influence of mercurial action, nor have they even at all alluded to the practice. This, if anything can they do? They must exist. They are were necessary, would, of itself, afford mecompelled to use the only weapons in their ply to those detractors who would insinuate, that the calonicl treatment of these cases has been long well known, and is a gene-rally employed mode of practice. The in-sufficiency of the operation unassisted by the not be sufficient, because death may occur rational treatment is pointed out by the case of Eliza Butler, which some time since occurred here. The notes of this case I hold in my hand, and Mr. Cullen, who furnished them to me, has promised to insert them for your perusal in the case book. See Cove 1. 1 for the purpose of gaining time. Such was hold also in my hand, notes of another case, likely to have happened in the case which the dissection of which I witnessed, and has just occurred. I proposed, adopted, and succeeded in the performance of this operation, in these tender subjects, fifteen years and the subjects, fifteen years and the subjects, fifteen years and them over to you. (See Case 2.) Let very young practitioner. Indeed it was by me remark, that both cases afford highly means of this operation that I first endea- important information. They not only voured to anatch the interesting but deserted show, as I have just said, that the opera-subjects of this cruel accident from the grasp tion cannot be depended on without the of death. Soon after the publication of my mercurial treatment be conjoined, but they

Manner in which the Injury kills;

I have been informed by the apothecary, tion being exceedingly laborious, and ac-companied by a loud sonorous rale. On which many have fallen, and daily fall. The fauces, an abscess was broken, and a quanbreathing was immediately relieved, and the child recovered. It was stated by the parent of the child, that it had some days before attempted to take a drink from the tion, extend to the bronchial tubes, and the spout of a tea-kettle containing boiling View the operation only as a means of mediate effects of the lesion, a suppurative, gaining time. Pursue an efficient or slower morbid action may a suppurative, or slower morbid action may a suppurative, may be equally destructed. This case also demonstrates, that destricted the caused by the mechanical obstruction. for stone can be child had not gotten to have sund; and as the lend a the bursting of the abscess was followed by rapid recovery, it is evident that the injury had not produced much effect on the chest.

Treatment, and its Occasions Fallure.

When you reflect on the tender objects of these injuries; on the delicate state of health in which the children of the poor of the age of those in whom the injury almost always and necessarily occurs; when you consider the importance of the injured part, and the nature of the operation of brouchotomy in an infant, you will not be surprised to find that success will sometimes fly from the hest-directed efforts. These remarks I make in consequence of having heard that it was exultingly, but absurdly said, on one occasion, "Here is a case in which the operation has been performed, here is a case in which calomel has been used, and yet here do we find that the chil4's life has not been saved." Is it not absurd to expect oniform success in such cases? But, I can say that the success will, in properly-treated cases, he almost constant. It will leave no room whatever to doubt the propriety of the measures proposed. I have lost one case, and only one, out of very many indeed, out of, at least, apwards of a dozen, and I think I should not have lost that one if the parents of the child had acted with discretion.

A case has been mentioned to me where the child, not withstanding every care, langed, after the calomel treatment and the operation had been conjointly employed, into a state of teverish excitement, which gradually led to great exhaustion and sinking. This I can well believe, I can also easily conceive that after such attacks, a state of general delicacy of health may often take place, the management of which

may require great judgment.

Whenever the accident in question occurs in your practice, lose no time in submitting your patient to mercurial action,-you may, if you please, assist it by leeches applied about the larenx. But do not let the apparent absence of danger, or of alarming symptoms, induce you to postpone, even for an hour, the most efficient line of practice which you can adopt: for these cases are often most treacherous. All appearance of scrious injury may be absent for hours after the accident, and then the most alarming symptoms will set in with great rapidity. by, that the parent is often lulled into a false security, and believes that no mischief with a pair of scissors. There was then has been don't prise gerhaps some little slight bleeding, which stopped in a few minutes.

Respiration was immediately carried on commenced and properly carried on, year through the wound. She seemed rather

s, without an operation, will be almost certain, If, however, you have not seen the case until dangerous or distressing symptoms have set in, you are first to consider, whether the state of your patient be such, that there exists a rational hope that the disease may be overtaken by the action of the remedy. If you think so, you administer, without having recourse to the operation of bronchotomy, two grains of calomel every half hour or hour, until relief be obtained. You should combine each dose of calomel with half a minim of tincture of opium, and as soon as symptoms of relief appear, the dose may be diminished, and the interval increased: but the remedy should be persisted in until all symptoms of distress are removed. On the other hand, if you find that the symptoms are so severe, and are becoming so rapidly worse, as to lead you to fear that dissolution may take place before a state of sufficient mercurial action can be excited, you must have recourse at once to the operation of bronchotomy, which will gain time for you, and afterwards pursue the mercurial treatment until you have secured the safety of your patient. These directions, if adopted, will enable you to steer these cases almost uniformly through their first danger; but to bring them to a full and happy termination, you must not lose sight of them until their tender systems have completely recovered from the shock caused by both injury and treatment.

Abstract of Cases alluded to.

Case 1 .- Eliza Butler, aged three years, was brought to the hospital at nine o'clock in the morning of the 14th of last July. At ten o'clock the preceding night she attempted to take a drink from the spout of a tea-kettle, which had been just removed boiling from the fire. Shortly after the accident she became dozy, and slept, and some hours after got wheezing. On admission she was warm, her pulse too quick to be counted. She had excessive dyspnœa. Respiration sixty in a minute and sonorous. Tracheal rattle prevented auscultation from being satisfactory. Lips and face rather livid; eyes languid; she was listless and drowsy; drank freely; her tongue and fances appeared white and scalded. Four grains of caloniel were given; and at eleven o'clock, that is, two hours after admission, tracheotomy being decided on, an incision was made with a scalpel along the mesial line. There was scarcely any bleeding. trachea was exposed with a blunt knife, and child often suffers so little in appear-traches was exposed with a blunt knife, and ancer after the moment of alarm has passed by the assistance of a hook was drawn forwards, when a circular piece was cut out

There seemed to be a slightly emphysematous state of the upper portions of the left lung; and parts of both lungs, particu-larly og their posterior aspect, were engorged with blood, were very livid, and solid, yet these parts did not sink in water. When a section was made of the denser portions of the lungs, puriform mucus could be expressed, in quantity, from the bronchia of the cut surface, and the intermediate parts exuded, at the same time, a quantity of a dark, livid, or bloody-like fluid. The remainder of the thoracic viscera, and those of the abdominal cavity, the lining membrane of the stomach included, were free from disease.

The vessels of the brain and of all its coverings were gorged with blood. There was a considerable quantity of a clear serum in the ventricles, and when the brain, which i was very firm for the age of the subject, was removed, there was found in the base of the cranium, and round the spinal marrow, a large quantity of reddish serum.

DESCRIPTION OF AN HERMAPHRODITE ORANG-OUTANG LATELY LIVING IN PHILADELPHIA.

Turs animal had black, thick, woolly, and frizzled hair, covering all parts of the body with the exception of the palms, the face, and the ears. Its skin was black, and it nails on all the fingers. The orbits of the eyes were prominent, the arms very long. It had no cheek pouches, nor any tail, nor a guttailst me, and there were rudingents, only, of these bestocks. The nose was many per left, and the facial angle more elevated, than in the simia astyrus of long. It had no cheek pouches, nor any tail, nor a guttain sac, and there were rudinger and the sac, and there were rudinger, only, of disease bestocks. The nose was more perfectly and the facial angle, or Woawen of Duvancel and F. Cavier. Should I for that in the similar styrus of Cavier is the little to the facial angle or Woawen of Duvancel and F. Cavier. Should I for that in the similar styrus of Cavier is the little than the same and the cavier and the facial angle of Woawen of Duvancel and F. Cavier. Should I for the training styrus of Cavier is the little than the same and the cavier and the

sal was two feet two inches. . Its arms were 154 inches long, the hand and fingers 51 inches, the lower extremities 11 inches, the foot was 44 inches long, the head and neck 111 inches long.

This interesting animal was imported into New York, from the island of Borneo; and at its death it was said to be rather less than two years of age. Each jaw contained twelve teeth; three molars, one canine, and two incisors, on each side. When standing erect, the fingers of the forehand nearly touched the ground; when advancing on a plane surface, he voluntarily assumed the crect attitude; he balanced himself with his long arms, on the slack rope, and climbed with the greatest agility; when he retired to sleep, he assumed a recumbent posture; he displayed great fondness for fruits of all descriptions, but particularly for grapes, and he possessed all the doeility and intelligence which is characteristic of the orangs. He died of a diarrhoes from excessive indulgence in fruits.

The orang genus has already been increased from one to six species. The present specimen differs from all the others hitherto described; it evidently pertains to the Gibbon family, or the long-armed orangs." and differs from the others in being of a universal black colour, in the facial line being less inclined, in the absence of the circle of gray hairs around the face, in the rudimentary state of the ischiatic callosities, and, with the exception of the active Gibbon, in the absence of the guttural sacs.

On the death of the animal there were found general adhesions of the peritoneum, the omentum, and the intestines. The glands of the mesentery were very much enlarged. There were white emptions, or, rather, ulcerated tubercles, on the peritoneum, such as are observed occasionally in scrofulous subjects, and inflammation of the mucous coat of the stomach, and the intestinum rectum.

Orangs have, occasionally, been dissected, and minute and laboured descriptions of their anatomy published. The present individual displayed remarkable peculiarities. The ligamentum rotundum was very strong; the liver resembled the human, having the same number of lobes, &c. The appendix vermiformis was very large; the contents of the thorax displayed a close analogy to those of the human being. The ventricles of Morgagni were rather large, although not communicating with a sac in the throat, as in the simia satyrus and some monkeys; the

^{*} The type of which is the Simia tar, (Linn.) to

sternum was composed of only two please, like that bone in man, in which respect it differs from the simine with tails. There were twenty-five rings to the traches, four-teen ribs one-ach side, four-teen dorsal vertebræ, seven cervical, five lumbar, five sacral, and five csecygeal; but the most remarkable peculiarity remains to be noticed; the subject proved to be a complete hermaphrodite.

Hermaphrodism, that is to say, individuals uniting in themselves the means of reproduction, without the concurrence of other individuals of their own species, appears to be in some sort a vegetable attribute, as among plants the class Dioccia (Linneus) is the only one not hermaphrodite. The nearer the animal approaches to the vegetable kingdom, the more frequent and complete are the instances of her-maphrodism. This is of two distinct kinds: in the one it is absolute, the animal possessing within itself the powers of reproduction, as is instanced in the bivalve shells (the oyster for instance), in some of the multivalves (as the chiton), and in the zoophytes, the sholothuria, &c.; whilst in univalve shells, on the contrary, such as the helix, limnes, planorbis, &c., although they unite the two sexes, yet the union of two individuals is necessary to fecundation. The common garden snail is a familiar example. Animals of this description are properly termed "androgynous."

The disposition, then, to hermaphrodism is more rare as we advance in the scale of perfection, or, rather, to a more complex organization. Those cases which are said to have occurred in the higher orders of animals, may, with few exceptions, he attri-buted to mal-conformation of the genital organs, and to an admixture of the two sexes, which, according to the observations of Sir E. Home and Mr. John Hunter, are of more frequent occurrence in the bull than in any other of the mammifera; but in no instance have these authors found the assemblage of the organs of both sexes complete, some or other of the organs being absent, or existing only in a rudimentary state. The case which most nearly approaches in perfection to the subject of the present description, is that detailed by Mascagni in the "Bulletin de la Faculte de Medecine," for 1811, p. 176," where he describes a bull, with all the male organs, and with ovaries, uterus, and vagina, but in place of a vulva, the vagina had its orifice in the urethra. There is also another case. somewhat similar, described in the Med. Repository, No. 45, of a human individual, in Lisbon, uniting both sexes in apparently great perfection. The subject was twentyone years of age, was twice pregnant, and aborted at the third and fifth months. It is true that although the penis and the testicle

vidual, wide "Decembair of this ledividual, wide "Decembair of this ledividual, wide "Decembair desa Sciences Medicales," art. "Cas Rares." The above observations will at least demonstrate the possibility of the occurrence of complete hermaphrodites, even in the highest class of animals,

The specimen which forms the subject of the present description will furnish us, perhaps, with the nearest approach to a complete union of the sexes in the same individual which has been detailed; and is the only instance, so far as we have observed, of a circumstance of this kind occurring in the monkey race. In the present instance the penis was about one inch in length, subject to erections, and terminated, as usual, in a glans, but imperforate, a deep groove on the inferior surface serving as a rudimentary urethra. This groove extended about twothirds of the length of the penis, the remaining portion being covered with a thin, cuticular, diaphanous membrane, which also closed the external orifice of the vagina. being extended across the vulva. The vagina was rather large, and displayed transverse strize. Remains of the nymphic and the labia externa were visible; the mentus urinarius opened beneath the pubis into the vagina; the urine must have been directed along the groove of the penis by the membrane obstructing the orifice of the vagina. The os tincæ was surrounded by small globular glands, the orifice and cervix admitting a large probe into the cavity of the uterus, which organ appeared to be perfect, with all its appendages; the round and broad ligaments, together with well-pro-nounced ovaries, were all in situ.* The scrotum was divided, consisting of a sac on each side of the labia externa, at the base of the penis, covered with hair. The testicles lay beneath the skin of the groin, about two inches from the symphisis pubis, obliquely outwards and upwards. They appeared to be perfectly formed, with the epididymis &c. The most accurate examination could not discover vesiculæ seminales, but an opening into the vagina, above the meatus urinarius, appeared to be the orifice of the vas deferens. The testicles were unfortunately separated from the body, during the process of skinning.

Admitting what in reality appeared to be the fact, that all the essential organs of both sexes were perfect in this individual, had the subject lived to adult ago, most interesting results might have been elicited. Could not the animal have been impregnated by the male individual, by rupturing the sent-sent closing the vulva? Or, by mastur-

CASE OF

INTESTINAL CONCRETION.

OR, ENTEROLITHUS.

To the Editor of THE LANCET.

Sin,-I am induced to send you a short count of a case of intestinal concretion. or enterolithus, with some observations on the subject, because the attention of the profession, other to public or private practice, is said to estimate form of disease.

I remain, your obedient agreent,

J. L. IRIN, Surge Halifax, Yorkshire, March 12, 1836.

A short time ago I was requested to see a man in the country, an under-gardener by occupation, æt. 31. of a naturally robust constitution, who had always enjoyed excellent health, until within four or five months previous to the time at which I was consulted. His symptoms at this period were, pain in the lower part of the abdomen, more particularly in the right iliac region, sometimes relieved by pressure, at other times aggravated by it, which had continued for several months, though varying constantly in its degree of violence; along with this there was an irregular state of the bowels, costiveness and purging alternating ; the discharge often watery, tinged with blood, and attended with tenesmus.

His digestive organs were much impaired, having a furred tongue, dry skin, frequent thirst, headache, bad appetite, loss of strength. His pulse was, however, nearly untural, and there was little or no fever. His general appearance had undergone a considerable change within the last three or him to such a degree that he could only attend to the lighter duties of his occupation. As the bowels were in this irregular state, and as the pain was not at this time increased on pressure, nor such as indicated blood-letting, I ordered him a brisk purge of calomel and jalap in the evening, to be followed up with a draught of sulphate of magnesia and rhubarb in the morning. He was directed to remain quiet for a day, and was put on low diet.

The effect of this medicine was to give considerable relief, though still the sensation of pain and weight in the abdomen was not removed; the pain, however, was feces I began to suspect that an accumulation of feces was the irritating cause, and produced his ailments; I therefore, after an interval of forty-eight hours, repeated the nurge of calomel and jalap, adding only a little pulvis cinnamomi compos. to relieve sufferings had been very great for four or an inch or two above the anus, he had, after many attempts, and intense pain, removed it by aid of a wooden scoop. Only a slight soreness at the lower part of the abdomen, and in the rectum, was now experienced. To allay this irritation of the mucous membrane I prescribed an emollient clyster, mucilaginous drinks, &c., so that in a few days he was able to return to his usual diet and employment.

Observations .- On examining the substance expelled, it appeared at first sight to be nothing but a large indurated mass of feces, in the shape of a ball, and as large as the fist, but when it had been repeatedly washed, a most curious-shaped intestinal concretion was found in the centre, resembling somewhat, in form, the tuberose root of an orchis, only having six or seven tubercles or excrescences instead of two. The following diagram may serve to give an idea of it, the tubercles taking their origin from or " Opman tlader,"

the feed matter ed rather less than an ounce. Its colour resembled that of rhubarby the woody fibres were distinct, and mixed with calcarcous deposits, both externally and internally. On cutting into it, the nucleus had more the appearance of a cherry-stone than anything else. There was a cavity of about the size found in those stones. four months, and his strength had failed A calcareous deposit of phosphate of lime surrounded it. The man felt conduced, that if the substance had been allowed to remain, it would have eaten its way through his abdomen, or permanently have stopped up the passage. I told him, that perhaps a cherry-tree would have grown from his body, like that which grew from the forchead of Munchausen's stag, and that had this happened, he would have become the most extraordinary gardener in the world. On more minutely examining this concretion, it was found to consist principally of woody fibre, and of a great quantity of a peculiar substance like amadon, t or the skin which covers the horns of deer when they now felt most in the left iliac region. From first shoot; it has the appearance of soft, the unhealthy and indurated state of his velvety, brown, spongy network, with short spicula. It is insoluble in water, partially soluble in alcohol, and blackens with sulphuric acid, burns with a slight flame, emits an odour of woody fibre, or tinder (of which it is a description), and heat reduces it to a charcoal. The calcareous deposits I found the griping of which he had complained, and to consist of phosphate of lime, ammonia, continued the cathartic draught. On visit- and magnesia, the presence of which I deing him the day but one after, I found his tected, by adopting the process mentioned symptoms entirely relieved and my patient by Dr. Turner in the 24th vol. of the Edinb. in high spirits; he informed me that his Med. and Sury. Journal, where there is a case of intestinal concretion related by Mr. five hours previous to and during his last Tortet, with Dr. Turner's analysis. In the evacuation, but that now he had succeeded case before us, I attribute the formation of in dislodging the cause of his illness. Hav- the concretion to the tornid state of the ing distinctly felt a hard substance pressing bowels, and to the swallowing of some inon the parts, whilst straining at stool, only digestible matter, as a cherry-stone, or some fruit stone of that description.

Had I not persevered in the use of brisk purgatives, the result might have been most untoward; or had I mistaken the symptoms for those of inflammation of the mucous membrane, and ordered leeching, counterirritants, and mild laxatives only, the exciting cause of derangement would not have been removed; or suppose I had attributed the causes of his sufferings to spasm, or nervous irritability, and had ordered a strong

^{*} The sketch was not sufficiently perfect to allow an engraving to be made from it, but the section has the appearance of rosette of riband, with six boses, the contre being an luch in diameter, and the lows each somewhat less in length; the diameter of the whole is about two and a half inches. Ep. L.

⁺ A variety of the believes ignarius, called " spunk."

entispasmodic, or been still worse than in the former case. These considerations are worthy of the atcention of practitioners, and as a young one, I thought myself fortunate in the happy termination of the case. It appeared from the symptoms that the effect of the first dose of the medicine was to remove the concretion and accumulated mass of feces from the right iliae region, or from the cacum and ilio-escal valve, and the left iliac region, when the repetition of the purge caused the enemy to retreat to the back door, and that the sigmoid flexure of the colon and curves of the rectum obviated in some measure its free passage, producing the sensation of pain so acutely felt at this period.

The rarity of these cases and the practical nature of the subject must plead my excuse for requesting a little more room in

your valuable Journal.

Intestinal concretions are not common in the human body, though several cases are recorded in Munro's work on the Morbid Anatomy of the Stomach, Gullet, and In-testines, in Good's Study of Medicine, in the Edinburgh Journal, in Andral's work, and in the works of other foreign authors. In ruminating animals they are often observed, especially in those whose food consists of luisks, beards of oats, &c., as in millers horses. The intestinal calculus has been tound occasionally to resemble the bezonr," found chiefly in the camel and the goat, and formerly used in Holland and Portugal as an alexipharmic. According to Drs. Fourcroy, Vauquelin, and Berthollet, eight kinds of hezoars have been described, those consisting of,-1st, Super-phosphate of line : 2nd, phosphate of magnesia; 3rd, phosphate of animonia and magnesia; 4th, biliary; 5th, resinous; 6th, fungoid; 7th, hairy; 8th, ligniform.

Dr. Good describes only three kinds of enterolithus, viz., bezoardus, calculus, and scybalum. As almost all animals are endowed with the power of separating and secreting lime and other carths from the blood for particular purposes, such as that of forming a shell, a covering for insects, Ac., so, in a morbid state of the system, generally, this secretion often takes place in abundance, and is poured forth into cavities where its accumulation and crystallization must be attended with mischief. The three varieties of true enterolithus are described as taking their origin in the following manner (See Copeland's " Diction-") :- 1st. Those whose nuclei have been for acd from inspistated hile, gall-stones, &c., to which saline and animal matter have at-

teched themselves. 2ndly. Those having nuclei constating of foreign bodies, such as fint-stones, seeds, husks, fragments of hone, around which the alimentary matter has collected and crystallized. 3rdly. Those which are formed entirely in the alimentary caual, and which are more or less homogeneous, and have no distinct nuclei.

The present case seems to belong to the second class. Concretions are found also in the intestines of persons who are in the babit of taking large doses of magnesia and chalk. Adjocerous and fatty concretions are occasionally formed. Dr. Elliotson in his valuable lectures, and in some of his papers, narrates cases of this description.

The morbid changes produced by these alvine concretions as described by Munro in the work previously alluded to, are either the formation of a sac, constrictions of the bowel, adhesions of the concretion to the inner coat of the intestine, or ulceration of the parts in which they are lodged, &c. The treatment which has been recommended may be divided into three modes, viz., purging, dissolution, and operation. Purging is certainly the best and most likely to succeed, provided the concretion is of limited size. Treatment by dissolution holds out a poor chance of success. That by operation, is a most formidable proceeding, either in adopting Munro's method, or that of M. Tortet; the former directs us to cut down upon the foreign body, in the space between the 12th rib, in the upper margin of the os ilium, or on that part where the peritoneal covering is deficient, then to make a hele in the colon, feel for the calculus, extract with the forceps, &c. The danger of this operation is evident enough, and, besides, how are we to be sure that the concretion will be found in the spot corresponding with the external incision? Mr. Tortet recommends to cut immediately upon the foreign body, supposing it can be distinctly felt through the skin, on the strength of the idea that the danger arising from wounds of the peritoneum and the exposure of the viscera to the contact of air has been exaggerated.

This operation might certainly be practised with a chance of success.

Illustrations of the Elementary Forms of Diseases. By R. Carrwell, M.D. Fasciculi 2-9. London. Longman. 4to. 1835-6.

SINCE we reviewed the first fasciculus of Dr. Carswell's work, eight more parts have appeared, the second and third illustrative of accinoma; the fourth of melanoma; the fifth of softening; the sixth of hemorrhage; the seventh of mortification; the eighth of

Prom rise train compound "padishr," of "padismeler, "subrrupted into "bed subr," of beyon," and translated "depellens regulates."

pus; the ninth of hypertrophy. Each fair a Vernation of her forms that termiciculus presents a comprehensive view of nate ralized and explained is always ingenious; of his broad chest and brawny shoulders. but it is the clear and logical manner in A more important variety of this form of which all the doctrines of morbid anatomy hypertrophy occurs in some involuntary with which every morbid form and shade is trophy of the heart is by no means uncomdelineated, which give the chief character mon, and is attributable only to excessive in this country, to put them at once in the The increase of bulk in one lung, or in one possession of every practitioner, and so to advance, more than any other recent publication, the progress of practical medicine.

We shall only notice the last and ninth fasciculus, which treats of hypertrophy,-"the consequence of an excess of the nutritive functions," and not, as has been supposed, "the consequence of an accumulation of the nutritive materials, from a diminished exercise of the act of decomposition."

Hypertrophy is sometimes congenital; at other times there is in the body a general tendency to an increased but imperfect development of various organs and tissues of the body, such as is observed in persons of a scrofulous constitution, where " the liver, the bones, the lymphatic glands, sometimes the brain, and, frequently, the upper lip, are, more or less, obviously enlarged."

The development of the adipose tissue is at times carried to an enormous extent under the influence of hereditary disposition, but more frequently under the influence of gourmanderie, leisure, and supersaturation of the system with aliment, as was remarkably exemplified in the ancient race of corporators, and the dignitaries of some Christian churches. Among the local causes of hypertrophy, Dr. Carswell enumerates "frequent and increased action of an organ in an unfrequent occurrence in the involunts the voluntary muscles, more especially in glia. those of the extremities: but in the blacksmith's arm, or in the leg of a Taglioni or observations on the state of the vessels in

perurophy is not to be one of the morbid conditions or products considered pathological. Notwithstanding which Dr. Carswell has denominated "ele-mentary forms of disease," because out of that the "superior extremitics of celebrated them, or their combinations, every organic danseuses suffer, and, when compared with disease, every appreciable anatomical lesion, the inferior, almost appear to be emaciated, is compounded. Several of the facts which while the legs of the drayman are sometimes are stated in the different fasciculi are new; so slender, that they seem hardly to posand the manner in which they are gene-sess sufficient strength to sustain the weight

are announced, and the beautiful accuracy muscles and double organs. Great hyperto this work, which is well calculated, as action, induced through the agency of cerwe at first predicated, to diffuse the import- tain diseased states of other organs, partiant discoveries made on the continent and cularly of the brain and nervous system. kidney, when the function of the other is suppressed, affords an interesting example of hypertrophy from a physiological increase of function, called into operation by the wants of the economy. The increased development of arteries and veins for carrying on a collateral circulation, the enlargement of the uterus and of the mamma in pregnancy, and, perhaps, the augmented bulk of one cerebral hemisphere, when the other is atrophied, may be legitimately referred to the same kind of hypertrophy.

The second cause of hypertrophy is " the existence of a mechanical obstacle to the accomplishment of the function of an organ." The most frequent cause of hypertrophy of the heart, the stomach, the bladder, and the biliary ducts, is some contraction or obstruction in the rifices of those organs, by which their muscular parietes are excited to increased action, and are, consequently, from the reason above stated, augmented in volume.

The long-continued influence of a morbid stimulus, is the most general cause of hypertrophy:-

"A state of irritation or chronic inflammation, is by far the most frequent cause of bypertrophy of the mucous, the cutaneous, the cellular, the fibrous, and the osseous tissues, and the glandular organs; nor is it the normal exercise of its function." It is muscles, besides being occasionally met...th this kind of hypertrophy which occurs in in the brain and the nerves, and their gan-

> Dr. Carswell has made is interesting

aneurysms,

The grat plate in the fasciculus which we are noticing, shows hypertrophy of the bronchi, the circular fibres of which are enlarged, and form transverse bands. Other figures represent emphysema, in which the dilated cells vary from the size of a pin's head to that of a cherry or a walnut. The second plate represents various forms of cardial hypertrophy. Figs. 1, 2, 3, of the third plate represent the morbid appearances which precede and accompany the formation of aneurysmal dilatation of the heart:—

"The serous membrane lining the internal surface of the ventricle, presents within a circumscribed space, varying from a quarter of an inch to one or two inches in breadth, or even from one half to two-thirds of its entire extent, a pale straw colour; it has become opaque, is closely united to the cellular tissue beneath it, which presents the same colour, and is considerably thickened. Occupying the situation in which these changes are perceived, and sometimes nearly to the same extent, are one, two, three, or more depressions, cavities, or sacs. These are lined by the scrous membrane and cellular tissue."

Fig. 4 presents a section of the tibia, with circumscribed bony enlargement or node. Traces of the external wall of the tibia are still observable, showing that the new osseous deposit took place on the inner surface of the periosteum.

The fourth plate represents ancurysmal and varicose dilatations of the arteries; also dilatation of the lymphatics and of the urethra. Fig. 2 is an example of ancurvsmal dilatations, which existed in all the arteries of the body, varying from the size of a hemp-seed to that of a large pea. Fig. 6 represents a dilatation of the urethra filled by a large stone. Although the sound had been frequently introduced, the presence of this stone had never been detected, " probably from the situation of the dilatation in the inferior surface of the penis, and the stone not projecting into the urethra." The patient was treated for varicoccle in the Hôtel Dieu of Paris.

he following is a very remarkable case of dilutation of the lymphatics in a young man of about 26 years of age:—

My friend, Amussat of Paris, was called to the Maint, who the day before had been seized with severe pain in the ab-

dial domen, followed by frequent vomiting.

These symptoms, and the presence of two swellings, one in each groin, nearly as large as an orange, left no doubt that the patient was labouring under the effects of strangulated hernia, but the state of pros-tration was such that reduction by an operation was not attempted. On examining the patient after death, the only remarkable circumstance observed was, enormous dila-tation of the lymphatics from both groins upwards, including the thoracic duct. The two swellings situated in the groin, and which at an early age of the patient had been treated as a case of double hernia (for we afterwards learned that he had worn a double truss from his boyhood), were found to be produced by great dilatation of the lymphatics of the inguinal glands. When cut into, instead of having a compact structure, they presented the appearance of a coarse sponge, from the size of all these vessels being increased, the most of them presenting from one to three lines in diameter. All the lymphatics of the pelvic and lumbar regions presented the same alteration in a still more remarkable degree. None of them were less than two, many of them from three to four lines, and the thoracic duct was from six to eight lines, in diameter. As no obstacle was found in the course or at the termination of the thoracio duct to account for the dilatation of the lymphatics in this singular case, and as these vessels had undergone no other perceptible change, I am disposed to consider it as an example of maiformation of these vessels.

> On the Analysis of the Blood and Urine in Health and Disease. With Directions for the Analysis of Urinary Calculi. By G. O. Ress. London, Longman, 1836. 8vo, pp. 147.

THE profession desire, says Mr. Rees, to know more of animal chemistry. Medical students already pursue the study vigorously, and their elders become unwilling to lack the scientific knowledge possessed by the apprentices. He therefore here presents them with what is described as "a concise view of those plans of analysis of the blood and urine , which may be performed" easily, cheaply, and usefully. The design is good, and it is gratifying to find the execution in the hands of a practical man, one who is not a mere book-maker. When the former, in addition to his experience, possesses a good understanding of words, and such clearness of head as will enable him to write comprehensibly, there is reason to congratulate the studious public on his literary labours. But few authors esteem the latter qualities. Consequently six volumes in every seven that come from the press, present us with such unpardonable outrages upon the English language, that their chief purpose is wholly lost and defeated. It gave us pleasure, therefore, to meet with a book whose author seemed alive to this error :-

"I have avoided as much as was possible those formal methods of description which have frequently disheartend the beginner from even reading a process, much more putting it to practice. If any such feeling he entertained by my readers, let me assure them that it is the reading, and reading only, that perplexes them; and that when once they have commenced the practice of the process, all confusion will pass away, and the facts become clearly and firmly impressed upon their minds."-Preface, p. iv.

We cannot altogether approve the " reading," that is to say, the writing, of this passage, and we have also, elsewhere, here and there, some rather perplexing, and some rather superfluous passages; for instance, in speaking of filtration, Mr. Rees advises that

"When pouring from any vessel into a filter, the lip of such vessel should be kept perfectly dry, otherwise the fluid is liable, after passing the lip, to run backwards to the bottom of the vessel, and thus be lost."

And his instructions for weighing are rather excessively described in the following passage, which does not end even with the lines which we have placed in italics :-

"Accuracy is greatly ensured by the habit of weighing by counterpoise, which is by balancing the substance to be weighed with dry powdered sand (or any other convenient powder); and then, on removing this substance, whose weight is to be ascertained, and counterpoising the sand in the balance with the weights, the most accurate result is obtained; for the number of grains, or parts of a grain required, must be identical in weight with the substance removed, before they can produce the same effect, of precisely balancing the sand."

Were it not very desirable to seize opportunities of urging our medical writers to pay more attention to the manner, as well as the matter of their books, we should not have delayed our praise of this volume to advert to a point which Mr. Rees himself the sugar with which it is admixed or some authors actually say, and what they when that principle has been present in

works. Sha a

Our remarks on the volume generally need not belong. We say as much as, and no more than, it deserves, in stating that it is an excellent book of instruction in analyses of the blood and the urine, in health and disease, quantitative and qualitative, with simple excess or decrease of their natural constituents, and with the addition, when present. of foreign substances. Personally familiar with all the processes, the author is not mere copyist, and he has repeated the researches of others where his own experience was too limited to be drawn upon for his descriptions.

His remarks as a medical practitioner are not numerous. The volume is, very properly, almost entirely confined to its expressed object. We extract, however, a few remarks by way of specimen, and with them close our notice.

Extraneous Principles in Urine .- " The urine frequently presents the various odours and colours of vegetable matters which are taken into the stomach; and the examiner must be on his guard against being deceived by such appearances. Thus, I have known a patient on the point of being treated for hamaturia, when the urine (by a mere chance) falling under my observation. I discovered the red coloration to proceed from the presence of a vegetable matter. On inquiry, the patient stated that he had been eating a salad, of which beetroot was an ingredient, during the last eight or ten days of his medical friend's visits."

" Mercury has been said to exist in the urine of those who use frictions with mercurial cintinents. This observation was made by Cantu, who obtained metallic globules from a sediment. I had occasion to examine the urine of a person who was salivated from large doses of calomel, but could not discover any trace of mercury

" Iodine always exists in the urine of those who take it internally. I have detected it in the urine of an individual who had taken only one grain of the remedy, and that in three separate doses of onethird of a grain each.

Diabetes .- " The great difficulty to be overcome in this examination is that of determining the proportion of urea; for in his preface presented to our attention. pletely prevents the crystallization on the We could fill a Lancer any day with the exposition of the difference between what urine have been stated to the state of t consideral made some experiments at the subject, from which be concluded that ures is voided by diabetic patients in the same quantity per diem as by healthy individuals. His method of detection was by plunging a mixture of the fluid with nitric acid into a freezing mixture, formed with ice and common salt; at this temperature a crystallization of nitrate of wrea occurred."

Silica in Calculi .- " This substance was twice detected by Vauquelin and Fourcroy during their laborious researches into the nature and composition of urinary concretions. Venables also reports the case of a woman who passed a calculus containing silica. It seems highly probable that this substance may exist in small proportion in most calculi; nor are we to be surprised at its being overlooked by those who examine the concretions; for, to do justice to such an investigation, it would be necessary to sacrifice the greater portion of most calculi, which is seldom permitted to the chemist, since such minute investigation has rarely been the desideratum of those who subject their specimens to his operations."

GERMAN JOURNALS.

Rust's Mayazin für die Gesammte Heilkunde. Vol. 45, Nos. 1., 11., 111.

WE resume our analysis of the German Journals. The last three numbers of Rust's Magazine contain the following communications, some of which we have already noticed:—

1. Report of the Medical Practice in the Hopital de la Charité, Berlin, from 1833 to 1834. By Dr. BARTELS.

2. Observations in Surgery and Ophthalmology. By Dr. Buck.

- 3. Remarks on an Epidemic of Dysentery at Cottbus in the year 1834. By Dr.
- 4. Fracture of the Skull, with Medullary Cancer in the Cavity of the Cranium. By Professor Wutzer.
- 5. Observation of a Case of Carsarean Operation. By Dr. KRANEFUSS. (Analyzed in The Lancet of Jan. 30th, page 700.)
- On the Difference between Congestion and Inflammation. By Professor NAUMANN, of Bonn.
- On Secondary Abscess. By Dr. NASSE.

8. Some Remarks on the Gout. By Pro-

STATISTICS OF " LA CHARITE,"

The 1 is a lengthened report of the most interesting cases &c. that present I them-

selves at the medical clinique of *Le Charitt*, Berlin, during the year 1833-34. We can only afford space for a notice of the statistical summary.

During the summer session 105 patients were treated; of these were

Cured, 57; incurable, 7; removed to other establishments, 12; died, 12; remained under treatment, 17,

During the winter session 141 patients were treated; of these were

Cured, 81; improved, 7; transferred, 11; died, 23; remained, 19.

Thus of 246 patients treated we have,— 128 cured and 35 deaths; while the remainder were either imperfectly cured or incurable.

The paper No. 2, entitled "Observations in Surgery and Ophthalmology," by Dr. Buck, contains a division entitled

POLYPI OF THE UTERUS.

The three following cases of uterine polypi present each several points of interest. In the first, we find an example of extirpation of the tumour while contained in the cavity of the uterus, an operation which most writers have considered as impracticable, though the present case shows that it may be had recourse to with full success.

Case 1.—A poor woman, forty-six years of age, generally enjoying good health, the mother of six children, was seized at the age of forty-four, with a severe hemorrhage from the uterus, which continued for eight days, and was attributed to fatigue and exposure to cold. Her menstrual periods had always been natural, and the discharge did not return again for twelve months; during this time, however, she experienced constant weight in the hypogastrium, with acute stitches in the sides, pain in the pelvis, and difficulty of making water. After the lapse of a year the hemorrhage returned, with aggravation of the symptoms, and was repeated at short intervals. The author being called on to see the patient in January 1834, found that the loss of blood had been replaced by a fluor albus. The woman was now very much reduced; her general appearance was cachectic, and she was unable to leave the bed; she had severe pain about the iliac region, which was aggravated on pressure, although nothing could be discovered in the shape of tumour, induration, &c.; the pulse was small and weak; cough frequent; she vomited occasionally, and was unable to bear anything but light food; she complained from time to time of weak labour-pains. On examination the uterus was found occupying its normal situation; the inferior segment not developed, but soft and thin; the lips of the os tince were completely

effaced, and the uterine orifice itself was di-lated to the size of a sixpence invelores stituted lady, and the following manner.

tremities of the tubes, oiled, and furnished the patient remained free from inflam-with their threads, along the left index-finger, as high up as possible along the root of the interest were restored by invigorating the polypus. One branch of the instrument being fixed, the operator, turning the con-cave surface of the second branch toward, third year, and gave birth to five children the polypus, succeeded in embracing the the polypus, succeeded in emoracing succeeds with his ligature, and fixing the two ing always appeared within the first twelve ing the uterus the operator took the precaution of exercising the pressure required for manusuring his instrument, rather on the polypus than against the sides of the uterus. However, the latter organ did not experience any pain or contraction, although frequently stimulated by the branches of the instrument. The ligature was gradually tightened for eight days, at the end of which period it came away, but, on examining, it appeared that only one-half the tumour had been destroyed. A second ligature was now applied, but with much more difficulty than the first, because the body of the polypus was reduced in size, while its peduncle seemed very thick and fibrous.

The effects of the copious foul discharge were counteracted by frequent injection of an antiseptic lotion. The unquiet state of the patient induced Dr. Buck to remove the ligature in a few days; he could now discover nothing but some fibrinous concretions, that were soon discharged with the pus. In fourteen days the polypus seemed completely destroyed, the uterus had recovered its normal form; the general symptoms rapidly diminished, and at the expiration of two months the female perfectly recovered her health, and the menses again became regular.

o issa lo st 47 chesticks), so as to admit the index-inger. menced to menstruste regularly every four On passing the finger into the cavity of the weeks at the age of eight years. This state uterus it was easy to feel and determine the existence of a polypus of the size of a large companied by any other sign of precocious pear, which was implanted into the fundus development. After having continued for pear. Which which are an and did not descend quite so far down as six months, the catamenta disappeared until the os tincze. It was impossible to reach the the age of fourteen, and continued regupreduncle with the finger, but the inferior larly until the patient's sixteenth year, portion of the tumour, which was quite in when they were suddenly arrested by a sensible could be circumscribed. The au fright. Four weeks afterwards, on the very thors first care was to improve the patient's day that the menses were accustomed to health, and, if possible, promete the descent appear, the patient was attacked with vioof the tumour into the vagina. For this lent inflammation of the throat (angina latter purpose he administered the secale tonsillaris), which threatened suffocation. cornutum, but without effect. The general This inflammation was subdued by proper symptoms now became more pressing; comeans, and the catamenta reappeared in pious discharge of foul mucus: severe cough four weeks, but wore, on several occasions, and pain in the chest; watery diarrhorn; in the course of the year, supplied by a rehectic fever &c. set in. An operation besturn of the anging: the consequence of this came indispensable, and was performed in repeated inflammation was an induration, with tamefaction of the right amygdala, The patient being placed in a demi-re-cumbent posture on the edge of her bed, the operator, who employed the instrument of Jorg, commenced by introducing the ex-tremities of the tubes, oiled, and furnished

Madame S. was married in her twentywithin eleven years; each labour was diffihours after delivery, and reduced the patient to a state of great debility. During her pregnancy, and while suckling her four first children. Madame S. was free from inflammation of the throat, but six weeks after her last delivery this affection returned on three several occasions. After a lapse of two years, the patient, now thirty-six years of age, was seized with severe loss of blood from the uterus, with pain in the hypogastric region, and a dragging sensation in the loins. From this period the hemorrhage was repeated, at first every six or four months, and, latterly, every three or four weeks, and was always preceded by some mental contrariety. She now complained of increased debility; pain in the lower part of the abdomen; difficulty of making water; the bowels were irregular, and, from time to time, a pricking pain was felt in the mamma. The inflammation of the throat did not reappear.

In this state the patient continued for several years to lose a large quantity of blood. In the month of October, 19 during an effort which the patient - a large body was suddenly neglecte. beyond the external labin, with a distinct for a particular of the control of

stook the disease for inversion of the sterus, and after vain attempts at replacing the organ, recommended astringent and tonic remedies.

These means were of no benefit, and in the year 1830, Dr. Buck was called on to visit the patient, whom he found excessively reduced by the repeated floodings; her body was covered with a cold clammy sweat; she complained much of giddiness inche head, and a periodical dragging feel in the right thigh; the face was pale; the eye dull; the pulse small, frequent, and intermitting; the nights were disturbed; the bowels very costive; the excretion of urine frequent and painful; the blood discharged was sometimes dark and clotted, sometimes thin and watery. On external examination the abdomen seemed soft, even a hand's breadth above the right ileum, where the patient complained of a constant dragging pain not increased by pressure. There was no trace of depression or curvature above the pubic symphysis; the vagina was occupied by a round body as large as a closed fist, quite insensible to pressure, and of a firm smooth surface. The tumour did not yield under compressions, but was compact and dense. The pedancle, two inches in thickness, was not completely surrounded by the os uteri. Where the extremity of the peduncle joined the vagina, there could be felt above and somewhat to the left side, a semilunar, slightly elevated and tumefied edge, with a depression, but everywhere else a flat retiring angle. It was impossible to introduce the finger, or a probe, into the depression. The author considered the body to be a polypus, which was attached to the neck, and by its pressure had closed up the os uteri.

Although this body had been considered by most of the patient's medical attendants as complete inversion, with prolapsus, of the nterus, while the state of the os tince rendered the diagnosis still more difficult, yet two principal reasons induced the author to adopt the idea of a polypus: first, its insensibility to pressure with the nail, a circumstance never observed in the uterus; and. secondly, the manner in which the tumour made its appearance externally, for complete eversion of the uterus is inconceivable. except immediately after delivery; and the patient's last child was twelve years old, and the symptoms did not commence until three years after her last labour.

The removal of the foreign body was evidently the only remedy from which any benefit could be obtained. The general th of the patient was first improved by

the local treatment consisted in washing the parts with cold water. By these means a repetition of the flooding was prevented, and for six weeks the patient was attacked only twice, while the general health im-

proved in proportion.

A ligature of silver wire was passed round the temour, about an inch from the extremity of the peduncle; in about twelve days the tumour began to soften and come away in a sanguincous, purulent, foul discharge: on examining the vagina, the vaginal portion of the uterus, which in size and properties resembled an organ a few days artic delivery, was found in a normal state, filling the cavity of the sa-crum; the os uter had an irregular angular form; some fragments of the polypus adhered to the anterior lip, and were partially removed by the finger; the rest came away with the pus.

Six weeks after the operation, the patient, who for ten years had remained free from any inflammation of the throat, was again attacked with this affection in a very severe degree; however, the symptoms were removed by a treatment with mercury and camphor. During the six months which followed the operation, the patient had no flooding whatever; the catamenia then appeared, at first somewhat abundant, but natural afterwards. At the present day, five years after the operation, Madame S. enjoys perfect health.

Case 3 .- A female, originally of healthy constitution, forty-four years of age, whose catamenia always were regular, though somewhat profuse, gave birth, within a period of thirteen years, to three healthy children, of whom the youngest is six years old. Her husband, a powerful man, forty years of age, was seized about two years previously to the present period, with an erotic monomania, under the influence of which he had connection with his wife more than four times a day for the space of a fortnight. Immediately after this the menstrual discharge became more profuse, the intervals more short, and since April, 1833, a constant discharge took place from the vagina, of blood, or whitish mucus. If we except a more frequent desire to pass water, the patient suffered under no local pain beyond an uneasiness about the pelvis; the appetite, bowels, sleep, &c., were regular. The flooding however continued, and Dr. Buck saw the patient in the summer of 1833; she was now very much reduced, the countenance pale, and the temper very irritable. The loss of blood was moderated by proper regimen, alum, bark, and the attents to complete rest of mind and body; mineral acids. On examining the vagina, the took internally an infusio summit milliabilit and acids. With mineral acids, bark, labelit and area, with mineral acids, bark, found swollen, and hard; the os tince and from the found was given in the even-somewhat dilated; those symptoms, joined lags, and the bowels regulated by Rements; to the obstinate nature of the disease, induced the author to diagnosticate a polypus still enclosed in the body of the uterus. One evening, the flooding, which had been suspended for ten days, having returned with increased violence, the patient began to experience severe pains, similar to those of labour, which continued with brief intervals for about an hour and a balf; after the expiration of this time, the author recognised by the touch the presence of a large, hard, pyriform, perfectly insensible polypus filling the vagins.

The operation was performed in this case as in the two former; the ligature came away on the sixth day, and the remnant of the tumour was easily extracted from the vagins. The polypiss had lost nearly half of its volume, presented a yellow-white surface, a fleshy consistence, and was lined with a smooth miscous envelope. All discharge now ceased, and the patient recovered her former health under the use of strengthening remedies, bark, colombo root,

tinct. ferri acetici æth., &c.

The above cases of uterine polypus are calculated to give rise to some reflections of a practical nature which are not without interest. Whenever a female is subject to any discharge from the vagina, whether of blood, or mucus, or not, it should be an invariable rule with the physician immediately to examine the state of the uterus and internal organs of generation. In the first of the cases now before us, the true nature of the disease had been mistaken for a length of time, and the patient's life brought into great hazard. In the third, the ordinary symptoms of uterine polypus were altogether absent; however, the state of the os uteri, and the obstinate nature of the discharge from the vagina, led to the idea of polypus, and the progress of the disease soon removed all doubts upon the subject-The process by which a polypus makes its way into the vagina is not a passive one; the tumour, distending and stimulating the body of the uterus, produces an action similar to that of labour; the neck of the uterus is effaced, the os tincæ softens and becomes dilatable, labour pains more or less severe set in, and the foreign body is expelled into the vagina with many of the symptoms of true labour. This is well illustrated in the third case, where the period of time during which the tumour was being expelled. lasted for an hour and a half. In many cases, however, the passage of the polypus through the os uteri is not accompanied by any very remarkable phenomena.

The possibility of placing a ligature round

TOTAL OF the foreign body. merus, and whenever the os steri is moderately dilated. is fully established by the first case we have reported; and the operation is indicated whenever the uterus is not sufficiently irritable to expel the tumour into the vagina, while the life of the patient is endangered by the constant loss of blood. This passive condition of the uterus is even favourable to the success of the operation, from which we should not be deterred by any idea of its difficulty. The presence of a polypus in the cavity of the uterus may be concluded when, under the circumstances alluded to, we feel an insensible moveable body through the dilated os uteri. As long as the polypus is closely embraced by the uterus, and the os tincæ contracted, the symptoms are generally of a mild nature, and we are not called on to interfere in a case where all operation would be impossible.

Experience also proves that we are not to adhere too strictly to the opinion of some writers who reject the operation whenever the general health of the nationt is very much deteriorated: when hectic fever, with anasarca, diarrheea, vomiting, &c., have existed for any time. The first and second cases prove that under these unfavourable circumstances the removal of the polypus, so far from hastening the patient's death, may be speedily followed by rapid recovery. Writers generally describe polypus of the fundus uteri, as being attended with severe flooding, while those which arise from the neck or os tincæ produce little or no loss of blood, but rather an abundant fluor albus. This rule admits of several exceptions. Times in the two first cases we observe exactly the contrary. In the first the polypus was attached to the fundus uteri, the organ itself was relaxed, and the os tincæ dilated, yet the hemorrhage was moderate, and during the last six weeks nothing came away except a quantity of mucous fluid; while, in the second case, where the tumour was atached either to the cervix uteri or one of the lips of the os tincze, the floodings continued with great severity for ten years, yet the tumour was not of a spongy nature, but This circumstance gave no certain editor-tion of the point into which Theolypus was inserted, which we can not determine. without . Seated and careful examination.

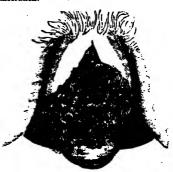

NAL CYSTOCELE

The following is a curious case of very re disease :-

Case.-A woman, 54 years of age, appaintly of good constitution, gave birth to her cond and last child twelve years back. he labour was difficult, and the midwife, ecording to her own account, obliged to move the placenta. The patient, however, sed through the first few months withut any accident, but in the following years ie frequently experienced a sensation as if vacuum were suddenly formed in the lower art of the abdomen by the descent of somering which caused a pressure in the vagina, pined to pain. These sensations continued or some years, when one day she felt a ound firm body in the vagina, which beame more palpable whenever she made any odily exertion. After the lapse of a few ears this body protruded externally beyond te orifice of the vagina, and was at first asily replaced by the patient. At length, owever, the tumour became more enlarged, ithin the labia externa. There was no ifficulty of making water; in this state she ontinued to suffer for three months, until redical aid became indispensable.

The author, Dr. Buck (whose "Observa-The lower third was free from excres- tural position. pon the tomour. The disease

nosticated as a complete prolapsus of the uterus, which, in consequence of the contact with air, urine, &c., had taken on cancerous ulceration.

Several surgeons and acconcheurs by ud she found it impossible to return it whom the patient was examined being of the same opinion, it was determined to oberate the removal of the tumour by carefully dissecting away the vagina from its connections with it. The intestinal canal being emptied, and the patient placed as in the ions" we are still analyzing), on examining operation for lithotomy, several assistants he organs of generation found a hard body endeavoured to introduce the catheter, with-s large as a seven-months' child's head ont success, until Dr. H. having by chance rojecting beyond the external labia. The turned the instrument in a nearly perpen-amour was everywhere dense, and covered dicular direction, passed it into the bladder, early all over with cauliflower excrescences a thing which certainly would not have thich produced a foul and ichorous secre- taken place had that viscus occupied its na-

ence, of a deep-real colour, and closely re- This circumstance threw some doubt for embled in appearance the vaginal segment the first time on the nature of the accident, f the uterus. A probe was introduced, half but as the end of the catheter could not n inch deep, into a transverse slit, which he felt externally, while it was discovered at as considered as the os tince. On passing the posterior wall of the tumour by introduction finger round the tumour, which very ing the finger into the rectum, the displaceasily bled and seemed closely united above ment of the bladder was considered as havthe lahia, it was impossible to introduce ing followed that of the uterus, and the opeie finger further than a blind angle that ration was continued. An incision of several verywhere circumscribed the fungous mass. 'inches was made into the thickened wall of he vagina, everted and prolapsed, seemed the vagina, underneath the tumour, and the cembrace the body of the tumour, and had latter dissected away with the bistoury, conontracted so close an union with the mem- stantly turned towards the swelling, lest the rane of the labia as to form nearly a straight rectum might be injured. However, inne to the perineum. On examination by stead of arriving at the substance of the rectum no trace of the uterus could be uterus, as was expected from the directum, the finger penetrated above into tion, the operator fell upon true muscular thick sac, appraisently the everted vagina fibres, where the catheter could now be felt, 'he author attempted in vain to introduce as a firm envelope, at least one quarter of an se catheter in the ordinary manner, as the inch thick, had been removed from the turifice of the urethra was excessively pain- mour. These two circumstances rendered and closed by large vegetations; besides, it evident that the tunour was in great part, no. "no was secreted in normal quantity, at least, composed of the bladder, without its at the temperature of the bladder, without its profession of the process of volume on the latter was any connected with the uterus. Another includes the produced by pressing som was now made, superiorly, near the vas diag orifice of the urethra, and continued down

to the first one; and the external coat of hard fungous masses was dissected away without the bladder being injured. The catheter could now distinctly he felt at all points of the parietes of the tumour, which had lost half of its volume, and being freed

from excrescences presented a smooth surface; it was partially replaced after a few gentle attempts, and the patient put in bed. She passed the first days pretty well; the

pain of the wound was slight; the appetite moderately good; the abdomen free from pain and not tumid. These favourable symptoms continued for more than three weeks after the operation, when the appetite began to give way. The patient became feverish; the edges of the wound dry and red. A colliquative diarrhoss now set in, and carried

off the patient on the sixth week.

On examining the body after death, the tumour which had been mistaken for the uterus was found to be the bladder, the inferior and posterior walls of which, clothed by the vagina, had gradually descended and projected beyond the great labia. The inferior part of the tumour, which still resembled the inferior segment of the uterus, presented a smooth surface, whose tissue was compact and of a cartilaginous consistence. It was necessary to make an incision of one inch and a half, from below upwards, to arrive at the bladder at this point.

The transverse fissure, which was considered as the os tineze, and contributed more than any other circumstance to the error of diagnosis, was formed by a peculiar fold of the vaginal mucous membrane, for which it is difficult to account. The extraordinary development which the vagina had attained in this case is worthy of notice; it was only the superior part, which in a normal position lies close to the bladder, that could have formed the exterior covering of the tumour. It is also evident that the bladder had not descended through a rupture in the parietes, amining the files at the newspaper agents of the vagina, since the latter membrane surrounded the tamour on all sides. The portion of the bladder which was displaced, was degenerated and thickened; the fundus, covered by the peritoneal tunic, still lay in the cavity of the pelvis, and was nearly in a healthy state. The uterus was also normal, but situated a little higher than it should have been in the hollow of the sacrum. If we reflect on the external appearance of this tumour, and its great resemblance to the inferior segment of the nterus, the persistence of volume, even after the turine was drawn off, and the absence of all symptoms that usually indicate an injury of the bladder, the difficulty of forming a correct diagnosis will be easily conceived. The treatment indicated after the error was recognised, consisted simply in removing the cancerous portion of the vagina, and returning, as far as was possible, the tumour to its natural position.

London, Baturday, March 19, 1836.

WHAT is to be done with the tax unon quackery? This question is now heard in every intelligent medical community. The answers to it are various, but all the experienced practitioners seem to agree in the opinion, that if an ANTI-MEDICAL-QUACK-ERY Society could be established, and could be brought into general action throughout the country, the downfall of empiricism would be rendered more certain by the operations of that society than by the influence of an Act of the legislature. If such a society could be established, what in the name of common sense is to prevent its establishment, but the apathy and indifference of the profession to their own respectability and interests, and to the health and security of the community. Behold what the KING OF THE QUACKS has done by his complete organization. He has a focus of action,-a den, where all his imps of mischief assemble, and receive their orders for the distribution of his universal poison. The organization of his system is complete, and it branches out into the whole of the provincial press of the country. On exin London, we find that nearly every country paper contains columns of advertisements, all puffing the wondrous efficacy of the "Universal Pills." These advertisements are also all dignified with "testimonials" in favour of the Quack and his system, from certificated members of the medical profession. All these things are seen. They are placed in bold relief before us, and the evil consequences are manifest in the increasing business of the undertaker; the public continue to be deluded; the poison is still swallowed by bushel- the science of medicine is degraded and insulted; and yet there are members the profession," ev a with heavy locks, who poolly

end bethe tit.

"and then significantly infiniste that "somet" g might be done, if an antiquackery society could be established." Observe. The quack wields but one instrument in accomplishing his object. That instrument is the press, which vomits forth, with horrible and destructive rapidity, advertiments, tracts, and even numbers of a periodical, in support of his nefarious projects. All his means, all his appliances, being concentrated in the powers of one instrument, that instrument is then brought to bear upon one material, namely, the ignorance, or, in other words, the credulity of the public.

What considerations, then, can deter the members of an honourable profession from boldly grappling with the monster FALSEmoon, in the very scene of its birth and activity? The public mind should be disabused, and there are no means so ready. or so efficient, for the accomplishment of this object, as that of resorting to the allpowerful aid of the press, which, by polluted hands, has been rendered the source of so much national mischief. "If an ANTI-MEDI-CAL-QUACKERY SOCIETY could be established,-why then, why then"-Oh, how sickening are these doubts and difficulties, where nothing but energy and common sense are required! If the Society were but in existence, what then would be the conduct of the guerists? Why they would instantly become subscribers, and obtain from the secretary a supply of tracts containing descriptive accounts of the last moments of the persons who had fallen victims to the use of " universal vegetable medicines," and accounts of the thousands of deaths which have been caused by the use of secret or quack medicines, in general. The best evidence of what might be the results of a combined tivity on the part of the members of the ion, thus directed to the diffusion of useful ki. xledge among the people, is almendy found in e fact, that in, those distraffs where if a actually known o the in-

to be habitants, that death has ensued from taking the "vegetable medicines," there the an antiale of the horrid stuff has been almost blished."

"Oh, but," it will be remarked, "the in"creasing intelligence of the public will, of
"itself, prove a sufficient corrective for the
"evil of quackery."

The persons who speak thus are themselves but sorry examples of the soundness of their own opinions. If man had been created on the 1st of last January, and if we had positive proof that he did not commence thinking in a rational manner until Monday last, at about nine o'clock in the morning, then, indeed, a hope might be entertained that the rapid growth of intelligence would lead to the substitution of a sound belief for a credulous faith. In short, REASON Would eject IGNORANCE from its throuc. How, we would ask, is the growth of intelligence to be promoted, unless the young plant be nursed and cultivated by wise and experienced hands? If credulity with respect to quackery existed only amongst the uneducated, or in the ranks of the poorer classes of the community, the apathetic might find some justification for their supineness; but when it is proved to demonstration, by what happened in the case of John Long, as well as in that of Monison, and the advertising disciples of HAHNEMANN, that the aristocracy of the land are the victims of misbelief with respect to the philosophic principles of the science of medicine, and are credulous, beyond conception, in all matters which have reference to the professions of quacks and the curative powers of their nostrums; we say that circumstances have arisen amongst us which demand the most energetic and powerful combination on the part of the profession, in order to exterminute an evil which has been, and still is, productive of so many fatal consequences to the community.

In considering this subject one thing must always be borne in mind, namely, that the means which could be employed for the and this publication and the dissemination of truth, are up of rational and list convictions, and veg. as much or even more at the disposal of the when the result of their conviction is only members of the profession, than they are at apparent in apathy, -when all the energies the disposal of a quack, whatever may be of the intellect are required to avert a the wealth which he has contrived to ex- frightful evil.—a conjecture is raised by the tort from the pockets of the people. Here, supine parties, that other persons who have then, we have at least ten thousand mem- no conviction,-who have only an absurd bers of an honographe profession, men of faith for steadying their principles, will enscience, moving in the highest ranks of deavour to convert what they do not regard munity, if there exist in the minds of medical practitioners a high-minded feeling regarding what is due to the profession to which they belong, and to the health and welfare of the nation, they will rise en masse against the miscreants who dare to wrest from them their privileges, and who are making the press a wide-spreading source of pollution to the public mind. Some there are who may look forward with confidence to what may be done by the House of Commons for the suppression quackery; but the day, we fear, is distant, when that House will act as it ought in such an emergency. Unfortunately the members of that assembly are not proof against ignorance in medical matters, and there are honourable gentlemen in that House who believe that their own valuable persons have been preserved for the benefit of the existing generation, and their talents for the advantage of posterity, by the careful and continual use of " Huxham's Tincture of Bark!" But what just ground can the members of the medical profession have for believing that any other body of men will exert themselves effectually for the suppression of medical quackery, while they themselves remain inactive? Who are the best judges in this matter? Assuredly medical men. Their opinions on the subject are formed after extensive research

society, and yet, can it be believed, they as a calamity into a public blessing! The allow TRUTH to experience the worst of a supposition is really monstrous, and is only contest in an honourable struggle with another indication of that unsound state of FALSEHOOD. The exhibition is a scandal understanding which, at the present peto the profession; and really, if there be riod, is but too prevalent among all classes any esprit du egres in the medical com- of society. We repeat, that it is in the power of the members of the profession, by a slight degree of organization amongst their members, to annihilate the pretcusions of quacks, and their odious slaying nostrums. In showing how that organization could be effected, we, at any rate, thus far, have discharged our duty, and if medical gentlemen will but co-operate in the manner we have explained, they shall not stand in need of the aid of THE LANCET towards giving efficiency and universality to their exertions.

ROYAL DUBLIN SOCIETY.

THE Royal Dublin Society has at length crossed the "Rubicon." By a vote of its members at a meeting recently held in Dublin, it has announced its determination to set Lord MULGRAVE, and the voice of the Irish people, at defiance. The wise and reasonable propositions submitted to the Society by the under-secretary for Ireland, Mr. DRUMMOND, were indignantly rejected at that meeting by a large majority. It was scarcely to be expected that there would be even a small minority to stand between the infuriated orange maniacs of the Society and their own destruction. What will be the result of the step thus boldly taken he them it is not difficult to conjecture . An we consider that the contest in be son the most impotent cotorie of the fallen orange est popular faction in Loland, and the gilled v' doy that ever stabled over t

There hest acquainted with both, for that ject for which this Society was established) rash termination of its political existence are owing, not to the suburban husbandry of to which its late measures must hasten it. the "gentlemen farmers" of that body, but Made up principally of the elite of the to the gradual progress of intelligence in orange squirearchy of the city and the this and in every other class of society in counter parts of Ireland, they have too long that country. We may venture to affirm drunk from the intoxicating cup of misrule that the simple introduction of the Scotch and bigotry, to yield without a struggle to plough and the Scotch drag, has enriched the dictates of reason and prudence. Like more fields and reclaimed more waste their desperate allies of the Irish corpora- lands in Ireland, has conferred more subtions, they would prefer the annihilation of stantial advantages on that country, than a Society, the advantages of which they all the lectures ever delivered by WADE pretend so much to respect, to its falling or by Lirron. We well recollect, indeed. under the management of the national mind, the anecdote of a gentleman who informed We have heard it stated, indeed, that the us that, walking one day through a farm charter of the Society warrants the course occupied by one of the Society's most scienwhich its possessors have pursued, and that tific husbandmen in the neighbourhood of in the exclusion of liberal men, only a Dublin, he inquired of a rustic neighbour legal right has been exercised. If, after whom he happened to meet, what was the what occurred in the case of Dr. Munnay, success of the owner. "Ah, Sir," was the the Charter really confers any such power, (reply, made with peculiar naiveté, " Mr.it ould be forthwith cancelled, and one is indeed an excellent farmer, and a very good pr. med on this topic, will, or ought to be, Of this Ulyssean species of agriculture, thus answered by the British Government; for if that Society, supported as it has been by grants from the national treasury, is to retain a sectarian or a political character, and to have power to exclude from its councils and its management, all those who happen not to entertain the same opinions as its present governors, then would it be better if the Society were altogether suppressed, than that it should remain a centre of dissension, and an instrument for the jassassination of character,-the most estianable in the country. The good which this Society has achieved for Ireland has, we perceive, been prominently urged as a proof of its proper administration, and as reason for its future preservation. We neither deny that it has accomplished some good, nor are advocates for its demolition. There can be no question that the labours of a society of this kind, under judicious direcwould be highly useful in the present freland; and we only express the present state, and being simply a spectacle feelings and wishes of the inimbitants when for the guze of the idle. Among the few we assert, that there are most anxious for its in Dublin who devote themselves to the

doubt forred by the institution have been grossly be suicidal capabilities of the Dublin in exaggerated, and purchased at souch too ution. Its composition and history were great an expense. The improvements at too well calculated to prepare those who made in the agriculture of Ireland (the obled on more rational principles should man, but the devil a one ever saw a stack of bstituted. The sophistry spoken and corn or a rick of hay in his haggard yet!" "ploughing the sand and sowing it with salt," the Royal Dublin Society achieved quite enough to incur the contempt of every practical cultivator in the country. It is only within the last eighteen months that a portion of the Society's Garden has been appropriated to the cultivation of the best kinds of fruit trees, garden vegetables, and field crops,-an object which, though particularly belonging to the Society, was previously much neglected. Every visitor of their garden must have observed that it had been falling for years into a state of ruin and decay; and if it now wears, as it certainly does, a different aspect, the improvement is attributable rather to the faste, the intelligence, and the attention, of the present conservator, than to the exertions of the Society itself. Then, if we look to the museum, we shall find it to be one mass of ignorant confusion from beginning to end, answering no kind of useful purpose in its well aware that the benefits are the plaint that the arrangement and nomenclature render the specimens and pre-paration, almost valueless. Let the telling them like if they desired as re-Society had for many years in pay a Ireland, they should commence the re man who had obtained in Ireland the easy reputation of a naturalist. The evidence he has left behind him seems to prove that he was either incompetent to the duties of his office, or too much occupied with the mysteries of "Orangeism," to attend to those of nature. An attempt, we understand, is now being made by Dr. Scouler to repair the discussion and diffusion of rancorou the errors and neglect of his predecessor; and anti-national politics, and the labour but much time is likely to clapse before so of its professors were turned into a jest. It difficult a task can be accomplished. It is unnecessary to detail the other neglects and misapplications of the funds of the Society. Those errors are, after all, secondary to the great question, whether the Society, with its present constitution, is calculated to effect the proper objects of such an institution. No one who comprehends the state of political feeling in Ireland, or the composition of the Society, will answer this question in the affirmative. To effect its legitimate purposes, the Society should possess the confidence of the people whom it purposes to instruct, or every effort to diffuse information among them, and improve their condition, will be fruitless. It was in a great measure the absence of a mutual feeling and good will between the Society and the people, which circumscribed within such narrow limits the influence and advantages of the Institution. To no purpose is the machinery of instruction exhibited, or the usual mode of communicating information adopted, while the guiding spirits of the didactic pageant are, in most instances, the judges who "charged" against the the same uncompromising and impartia liberties of the country, the crown-lawyers who hunted down its miserable population, the proprietary who expatriated them by conclude these remarks without advertin thousands, and the corporate burgesses who to, we believe, the only defence of the Sc carried with them into the Institution the same exclusive principles which made them objects of detestation to their fellow-citizens subject. Had these letters been written h ont of it. The ardent and sensitive temperament of the Irish refused to receive Society, the public would, of course, knoproffered favours from such hands, and the how to appreciate them at their prope community consequently left the junto in value; but coming from a writer profession the solitary enjoyment of those treasures of liberal principles, and, from his connection which the Society was intended to be the presumed to be sincere in his profess steward, and not the monopolist. The peo-ple of Ireland responded to the invitations their duplicity, and the ignerance of the of the Society to receive improvements at who saw read and its hands, as Demetrius replied to the Areo-them. Als, however, metaly sufficient t

mation at home. Unsupported by put's opinion the Society languished, its tia and means were wasted in unprofitable an oftentimes mischievous trifling, its lectur rooms became the lounge of the idle or th fashionable, its news and committee roon were converted into convenient centres for this spirit which so successfully achieve those evils which an ultra-party of big in the Society wish to perpetuate, as which it is the duty, as we believe it to I the inclination, of the present paternal go vernment of Ireland, to prevent. Suppor ed by the voice of a people anxious for in provement, and demanding but simple equa lity and justice, the Government are calle upon to defeat the malicious attempts : this faction to convert into a mere sociand political club, an institution and a pro perty created for the most part out of th public funds, and intended for national put poses. The Society, to be of any real advar tage to the country, must be liberalized, ar so constituted, that the religious or politic opinious of amember or of a professor sh. form no impediment to the admission the one, or the appointment of the oth For the attainment of this reasonable ., ject, the people look with deep, though coparatively silent, anxiety to the head of t Irish Government, who, in the adjudication the question, we have no doubt, will displa policy which has characterized all his mer sures since his arrival in Ircland. We cannot ciety which has appeared in print. W allude to the letters of Dr. Meyler on th an avowed Tory, or a known partisan of the n influenced t HRIDI

philosophic loyer of his ry, has made the pages of the "Mail" rehicle of his lucubrations, in order to ve them of their misguiding tenden-Was there no other medium in Dubin through which this ardent philanthropist could make known his love of country and his convictions of the utility of the Society? Were the columns of even the "Post" too ool folthe communication of his warm and benevolent feelings towards his benighted untrymen? Should he again, however, ke up the pen in defence of the Society, it ill. we apprehend, be not necessary to do which, in the first instance, was the juty of an honest man - to inform his readers to what party he really belongs.

ERINENSIS.

Dublin, March 10, 1836.

Hospital Statistics.—The fourth number of the first vol. of the Medicinische Annalen (German journal) contains a review of the medical clinique of the University of Heidelberg for the years 1832 3.4. The following stabilitial results may serve as a term of con-parison with those of our own hospitals. The number of patients treated during the sove period was 1401; the deaths were 62, civing a proportion of mortality as 1 to 145:366. The number of externe patients be ted was 1684; the deaths 83, or as 1 to p. 44.

et.

REJUDICE VERSUS SCIENCE .- To the Easter. - Sir: In further explanation of the farticle in The Lancer of March the 5th, No. 653, under the above head, it should be generally known, that three converted Jews have been appointed professors to King's College, London, for teaching the German, Spanish, and Hebrew languages. Neither of them has had a university education. Mr. Bernays, the professor of German, bought, since his appointment, a diploms of doctor of philosophy at Giessen, a university in the Grand Duchy of Hesse, but he never was entered there as a student. He taught first, in this country, in a Jewish establishment of Brixton. ** I am, Sir, your : obedient servant,

A CONSTANT READER.

The latter part of our correspondis there we have omitted. We cannot prove the statements which it conthe. Will restall to the former part, we systate that the table handles to the letter been attacked by paracless, to should we reverse to a monatorial the tri-

umph of Science versus Parsudice. To, divine, however, the principle on which is catholic institution receives into its both converted Jews, and rejects faithful Christiaus, is beyond our power.

LETTER FORM MR. HENTSCH.

To the Editor .- Sir : In your last week's number you gave a report of the meetings of the governors of the Free Hospital, held at the Gray's-inn Coffee house, respecting the dismissal from office of Mr. Tweedie and myself, which report contains (no doubt unintentionally) several inaccuracies,+ one of which, concerning Mr. Tweedie and myself. I beg leave to point out to your notice. Mr. Marsden is reported to have said that "since the publication of the testimonials. several subscribers had seceded from the charity, believing that the officers were encouraging quackery, and a representation of the fact was made to Mr. Hentsch and Mr. Tweedie, and a sort of promise obtained from them that the cause of complaint should be removed, but without realization." Now, Sir, this is incorrect. Mr. Marsden did not say so at the meeting, nor could he, such not being the fact. Neither Mr. Tweedie nor myself ever made a "sort of promise" that the cause of complaint should be removed, it being quite out of our power to compel Mr. Franks to cease publishing them. The insertion of the above in your next will much oblige, Sir, your obedient scrvant,

WM. HENTECH, Late Apothecary to the Free Hospital. 3, Furnival's-inn, Holborn;

3, Furnival's-inn, Holborn; 16th March, 1836.

t " Several" should perhaps be " one,"-ED. L.

LETTER PROM MR. TWEEDIE .- We have also received a letter from Mr. Tweedis, addressed "To the members of the medical profession," but at a very late hour in the week, and extended to a length which would render it impossible for us, from our arrangements, to give it insertion in this number of THE LANCET. However, we object to publishing what would, we fear (unintentionally, we are sure, on Mr. Tweedie's part), prove a very profitable advertisement of a quack medicine, even the name of which we decline again to admit into our pages. Our late report of some late proceedings at the Gray's-inn Coffee-house are stated, in a note to the Editor from Mr. Tweedie, to contain "two or three serious imperfections;" but these have not been specifically mentioned by him, or they should

onal, Professor, course of loctores by, on Diseases of the Brain and Nervous System: -LECTURE 1 .-- Introduction .- The peculiar difficulties which surround the investigation of nervous diseases; points to be weighed in considering the causes of those diseases; their complication with o her discuses; extreme obscurity of the ir path lo. v ; modern changes in their "moter; the senses of observation Pleas in their study; difficulties And by the disposition to theorize; de of the nervous force not generally different changes or lesions boin, producing nearly identical the brain not a single organ, telleby a vital unity; difficulmaies, by the same leison of the brain peing the most varied armptoms. the complications of sympathy; modifying influence of age; the great majority of the diseases of the nervous system present no perceptible changes of structure; reasons why pathological anatomy is at fault; chemical and nutritive changes of the brain; indications of the treatment of nervous diseases; influence of imagination; means of clearing obscure points in the pathology of the nervous system; order and spirit to be observed in the present course of lectures, 353.

Brain,-The various anatomical or pathological characters of cerebral hyperemia; considerations to be observed in examining its morbid appearances; influence of atmospheric temperature in producing cerebral congestion; other atmospheric effects; effects of stimulunts and narcotics on the brain; cerebral congestion from diseases within the brain; from affections of other organs; from v-nereal pleasure and abstinence. age, and mechanical forces; general symptoms of cerebral congestion; first variety . r form ; second, or coup de sang ; third, bemiplegia; fourth, paralysia; fifth, farious delirium ; different symptoms of cerebral desage; attempts to localize the corebral functions; con estion and other affections of the ce ebellum; conge tion of the spind marrow; terminat one of cer bral congestion; indications of treatment, 393,

LICTURE 4. - Encephalitis .- The most striking phen mens in the disturbed functions: lesions of the digestive and circulatory apparatus; lesions of respiration; modifications of symptoms; the three varieties of acute encephalities; practical importance of his division; deration and term nation c, the disease; treatment by bleeding and cold; different modes of applying cold; revulsives a d purgatives; mercury, is calone a specific in inflammation? character of the chronic orm of the t se; chronic inflammation of the cer-(Note to this lecture)-

the term encephalities, ayuntoms as lating the disease; three divisions it austomical characters and causes, 681.

11-1

LECTURE 5 .- Myelitie, or Inflammation of the Spinal Marrow - Division into a ute and chronic; anstomical characters, and parts which it attacks; causes and symptoms; lesions of motility; lesions of sensibility in the neighbourhood of the spine; in distant parts; diminution of sensibility in the disease; difficulty of deglutition and articulation; derangement of the digestive functions; of the circulation and respiration; modifications of the secretions; effects of the disease on the organs of generation; diagnosis; di-eases simulating irritation of the spinal marrow, according to the views of Messrs Griffin and Ens; duration, termination, and treatment of myelitis,

LECTURE 6 .- Anemia of the Brain and Cerebral Hemorrhage. - (1. Anemia) -Its simulation of hyperemia; anatomical characters; symptoms; delirium; delirium from withdrawing stimulants; disturbance of sensibility and motility; treatment. - (2. Cerebral Hemorrhage) -Impropriety of using the term apoplexy; parts of the brain in which it occurs; meningeal apoplexy; sanguineous cerebral cysts; appearance and source of the effused blood; period when cicutrization is effected; state of the brain near the effusion, of its mass, and of the m mb anes : causes and periods of corebral hemorrha, e; influence of a diminished aortic culiber; changes in the venous circulation; general pletbora; sex and age, 521.

LECTURE 7 .- Cerebral Hemorrhage (continued) -Symptoms of actual effusion; premonitory symptoms; the disease without them; symptoms depending on other morbid changes than effusion; case of effusion without a symptom of that lesion; paralysis as a symptom; case without paralysis; intermitting paralysis : hemorrhage into the cerebral hemispheres; bemislegia and its indications; sixteen cases of hemiplegia occupying the same side of the body as the lesion in the brain; inquiry into the portions of the brain sever-liv influencing the upper and lower extremities; effusion upon the brain as affecting motility; lesions of the pous varolii.

LECTURE 8.—Cerebral Hemorrhage (continued).—Lesions of Motility and Sensibility.—Does paralysis follow this lesion? On which side is it?—thirty-two cases of this lesion; which lobes the effusion occupies; hemorrhage into hoth cerebrum and cerebrilum; effusion of Mood into the spinal murrow; paraof muscles of the eves and cheeks;

and the blad of arminations of paralysis order of its disappearance; lesions of sensibility in the brain itself; modifications of sensibility in the skin and mucous membranes; disturbance of the organs of various portions of the brain particularly affected; blindness from the disease; modifications of hearing, 601.

Pals. . Prince ration .

LECTURE 9.—Cerebral Hemorrhage (continued).—Lecions of Intelligence.—Lecions principle of the Heldigence.—Lecions principle of the intellectual faculties at the moment of effusion; differences in the seat and extent of hemorrhage; no such lesion in spinal hemorrhage; state of the intellect after the effusion; affections of the speech, circulation, respiration, and generative organs in cerebral hemorrhage, 649.

Lecture 10.—Cerebral Hemorrhage (cocluded).—Peculiar Varieties.—Symptoms attending cerebral hemorrha, which do not seem characteristic of first class of symptoms; contraction arspansmodic affections of the limbs; there treatment; impulses to advance and treat; delirium and somnolency attaing apoplexy; symptoms uncome of with cerebral lesions; duration and ; gress of apoplexy; other varieties; treatment; abuse of venescrition, attenorby ralysis ca, ecially; prevention impoplexy; hypertrophy of the brain, 72.

Legaune 11.—Hypertrophy of the Newboas Centres.—Anatomical character of by-pertrophy of the cerebrum; co-by-pertrophy, with and without an ment of the cranium; causes tavo, the lesion; periods of occurrence, an symptoms; lesions of intelligence, sensibility, motility, respiration, and cillation, in cerebral by-pertrophy; its divisions into the chronic and acute periods; varieties and treatment; partial hypertrophy of the cerebrum; hypertrophy the cerebellum, and its influence on t genital apparatus; hypertrophy of spinal marcow, 761.

spinal marrow, 701.
LECTURE 12.—Alrophy of the Brain and Spinal Marrow.—General description distribution into congenital and grad acquired atrophy; great domination the nervous centres; symptoms changes in the ossessus parietes; chydrocephalus as one form; central following atrophy; seconds the brain normal but very sand from deposits in the basic that mark lible gradient to coreferon in particular, particular, and show the last class entire absence and second descriptions.

cerebral lobes; absende of

the posteor horn of the lateral ventricles; simplydiminution of the cerebral Animal kingdom, Treviranus division of, volume; aborce of the thalami and corpora strie; ages most subject to cerebral atroly; atrophy of the white central part and the pineal gland, 809. LECTURE 13. Atrophy of the Brain and Spinal Agrow (concluded).—Acrophy

of the pus varolii; measurements of the brain; atrophy of the cerebellum; complete absence of the cerebellum, and its inducace on the genital organs; sim VAphonia, case of, 903. fule diminution of its volume; atrophy. Apoplexy of the lungs, 101; inquests in cases of one side of the cerebellum only; of, 392; during pregnancy, 882. atrophy of the cerebellum conjoined; entire absence of the spinal chord; imperfections and diminutions in that chord; atrophy and absence of nervous protuberances; atrophy of the medulla oblongatu; ramollissement of the brain,

LECTURE 14 .- Ramollissement of the Nerrous Centres .- Anatomical appearances, in softening of various parts of the nervous pulp; variations chiefly in colour; lesions whose nature is wholly unknown; different seats of ramollissement in the cerebrum, in the hemispheres, in the central and deep parts, in the cerebellum and spinal marrow; causes of remollissement; common to all periods of life; symptoms, accompanied by derangements of intellect, of motion, and convulsions.

LECTURE 15 .- Ramollissement of the Nervous Centres (continued) .- Ramollissement, with contraction of the muscles; paralysis, convulsions, epilepsy, tetanus : lesions of motility and sensibility; readache; lesions of sight, hearing, and the nutritive processes; acute and chronic ramollissement, and their varieties; ramolissement without any symptoms; order of succession of the symptoms; affecting the same side of the body as the lesion in the brain, 921.

LECTURE 16 .- Ramallissement of the Nerrous Centres (concluded) .- Ramollissement of the central white parts; of the septum lucidum in particular; of the fornix and corpus callosum; peculiar phenomenon accompanying these ramellissements; their resemblance to acute Belladonna, preservative effect of, against hydrocephalus; ramo lissement of one lobe of the cerebrum; lesions of movement in that ramollissement; lesions of scusibility; general ramollissement of erobellam ; ramollis ement of the mesothe in the annual property anoplexy; ranollissement of the brain mass, 953. in the annular protuberance,

Marshral mass, 953.

of the wain, 522. Ma. 498.

Middle ir the posterior lobes; utrophy | Aneurysmal tumour of the orbit, treated by

Anti Medical Quackery Society, 949, 977. Autimony, tertarized, in pneumonia, 315; employment of, 882.

Antrum, disease of, 153. Anus, artificial, cured by a new process, 256; formation of, 561; produced by a wound, 571.

Aorta, diminished caliber of, 222.

Apothecaries' Company, regulations of, 11; effect of, 631; rejection of a student by, 636; meeting on the rejection, 668; address to, from the London University, 880.

Apprenticeships, medical, term of, 423. Arachnoid, hemorrhages into the cavity of, 45; false membranes of, 792.

Arsenic, poisoning from, 436; test for, 877. Arteries, state of, in inflammation, 87 (see also Med.-Chirurg. Review); new treatment of wounded, 331.

Artery, radial, wound of, 332; brachial, wound of, venesection of, 331.

Asthma thymicum, 301.

Atrophy, of the brain and spinal marrow, 84 (see Andral); of the valves of the heart, 946.

Auscultation in stone, 135; M. Raciborski on. 584. Austria, liberality of, respecting French de-

grees, 590. Avlesford, North, Union, medical contract for the poor at, 299.

Bailliere, Mr., letter from, 189. Barker, Mr., on gouty concretions, 821. Barry, Sir David, death of, 264.

Buttley, Mr., Sir H. Halford's puff of, 52. terminations; instances of paralysis Beau, M. on the movements of the heart, 827.

> Bedingfield, Mr., on a metropolitan medical union, 837.

> Bell, Sir C., address of, at the Middlesex Hospitul School, 89; on diseases of the spine, 230; letter from Edinburgh respecting, 641; appointment of, at Edinburgh, 170; a word of advice to, 668.

> scarlation; 300; remarkable effects of, in erysipelas, 758, 806.

Benedict, Prof. ssor, a ticles by, 56.

Benson, Dr., case by, of pulsation in the veins of the arm, 176.

Bieske, M., case by, of insanity, from sabre wounds of the head, 828.

Biology of Treviranus, 453.

Birmingham School of Medicine, 63, 840, Bladder, rupture of, 18; from a blow, 19; from a fall, 21; broken catheter extracted from, 532.

Empyema, lecture on, by Dr. Ros, won ; paracentesis thoracis in, 1888. of, 426 : vari-

Encaphalitis, scate, sympt ties, 120 ; treatment, 428 ; chronic, causes and symptoms of, 4:30.

Entomology, 145.

Epilepsy, from injury of the bead, \$(8); modified, case of, 697.

Enterelithus, case of, 965.

Epps, Dr., letter from, 319; on monopolies in medical education, 515.

Epulis, clinical lecture on, by Sir B. Brodie,

Erinensis on the conduct of the Royal Dublin Society, and the proceedings of Ministers,

Erysipelas, nitrate of silver in, 322; complicated, fatal case of, 322; lecture by Mr. head, case of, remarkable effects of the extract of belladonna in, 758, 806.

Erraia, 16, 128, 160, 224, 271, 320, 341, 472,

647, 728, 759, 808, 888.

 Erythema, characters of, 324. Evett, Mr., note from, 759.

Exfoliation of bone, reproduction after, 046, Extra-uterine fectation, discussion on a case of, 217; Dr. Ramsbotham's letter on, 266. Extravasation of urine, from external injuries,

19; in children, 20; local differences between, into cellular and serous tissues, 22.

facial nerve, section of, by disease, 45. Faraday, Mr., on the silicification of plants, 756.

Farnham, inquest at, 257, 263, 345, 351. Farr, Mr., lectures by, on hygiene, 240, 773. Features, artificial, 538.

. Feces and urine, non-secretion of, during many years, 702.

Fergusson, Dr., on medical aid for the sick Gouty concretions, case of, 821. poor, 747.

Ferral, Mr., note respecting, 919.

Fever, nature and causes of, 131; convalescence from, followed by death, 268; treatment of, Dr. Bright on, 596.

Fieschi, head of, 936.

Fingers, contraction of, 623.

Flame, nature and qualities of, S60.

Fleishmann, Dr., on belladonna as a preservative against scarlatina, 300.

Flogging, death from, 875.

Food of plants and animals, changes of, 103. Fosbroke, Dr., on diseases of the heart, 438, 629.

Fox, Mr., on the election of parochial medical officers, 941.

Fractures, bad effects of splints and tight Guislain, M., on gangrene of the lungs in the bandages in, 168, 245, 288; treatment of, without splints, 461; Mr. Wardrop on, Gun diseases, synopsis of without splints, 710; Dr. Wallace on, 627; Guthrie, Mr. op-ration on, 498; of the tibia, cured without splints, 242, of the finis and to the state of 920; operation of abuls, and of the femur, similarly treated,

blueding is come of, 250% Bear of the propole, 170; of the te Abula, with paralysis, 335; treatment of 384, 423 . death after, 384 . simple, of the ileg, followed by gangiene, 61 h ; of the jaw cases of, 741; of the perells, new mode of treating, 785; of the olecration, 807; at the thigh, BOT.

Free Hospital, Greville-street, proceedings at, 840, 944, 981.

Fungus medullaris, of the pelvis, 695, maligi nant, of the penis and groin, 694. Furlonge, Dr., case by, of modified epilepsy.

G

Liston on, 324; puncture in, 327; of the Gaugrene, senile, case of, 371; of the lungs in the insane, 793.

Gastritis, chronic, case of, 488.

Gustrodynia, creosote in, 124 275.

Gazette Medicale, January 1830, 772.

Guardians, boards of, contracts of, 309, 803. Generation of living and dead matter, 105.

Genital organs, effects of hypertrophy of the cerebellum on the, 765.

Geohegan, Dr., on poisoning by hydrocyanic acid. 175.

Gerron, Dr., on traumatic entaract, 4.3.

Gibson, Mr., case by, of spasmodic colic. 565.

Girten, Mr., on aucient and modern black nations, 40.

Glunders treated with creosote, 594.

Glottis, scalded, cases of, 9,13,

Goitre, lymphatic, ligature of thyroid arteries in, 252.

Gonorrhea, cases of, with condyloniata, 125, 157, 598; in the female, 435; crocsote in, 435; nitrate of silver in, 499,

Gonorrheal rheumatism, Mr. Samuel on,

Gowing, Mr., case by, of strangulated inguinal hernia, 699.

Goyraud, Dr., on inguino-intestinal hernia, 450.

Granger, Mr., present to, from his pupils,

Green, Mr., on the use of setons in hydrocele, 354; lecture by, on fatal simple fracture of the leg, 615.

Green, Dr. P. II., cases and remarks by. (See Hopital des Enfans.)

Gregory, Dr., report by, on small-pox and vaccination, 831.

Gregory's Conspectus, by Dr. Venables, 209, Grimstone, Mr., puff of, 52.

Grisolte, M., on colic from lead, 52,

insane, 793.

H

Hache, M., on pericardicis, 796 Habaemanuism in London, 755, 787, 840; doctrians of, 934.

Halford's, Ser H., puff by, of Mr. Battley. 195.

Hamilton, Dr., the late, 381.

Hancock, Dr., note from, 801.

Hawkens, Mr., on the skull of Dean Swift, 503.

Hemorrhage, into the arachnoid, 45; traumatic, researches in, 450; of the ceruballum, 601; cerebral, peculiar varieties of, M. Andral on, 729 : from the mouth, several case, 863; ligatures in, 934.

Hemorrhoid in the rectum, 295.

Head, pain in, treated with carbonate of iron and hydriodate of potash, 274; injury of, Hunturian Theatre of Anatomy, 7. 518.

Heart, case of disease of, 222; disease of, following rheumstism, 235; disease of, elucidating difficulties of disgnosis, 458; sounds and motions of, 501; Dr. Fosbrokev Hydrocele, 95; treated with seton, 334. on diagnosis of diseases of, 620; movements + Hydrocephalus, acute, of Abercrombie, S7. of, 827; Mr. Bryan on the sounds of Bob ; Hydrocyanic acid, poisoning by, 174. strophy of the valves of, 946.

Hecker's Annalou, articles in, 58; Vel. 2, Nos. 5 and 4, Vol. 3, No. 1, 867.

Heidelberg, hospital statistics at, 981.

Heifer, the, early breeding in, 876. Hemiplegia, M. Andral on, 401, 557. Hemming on uterine diseases, 144.

Hentsch and Tweedie, Messes., proceedings against, 840, 944; letters from, 981.

Hermaphrodism, an instance of, 375; in an orang-outang, 963.

Hernia, inguinal strangulated, 15, 75, 90, 155, 669; strangulated, cured with the air-pump, Tkin, Mr., case by, of amaurosis, 569. 58; ligature in umbilical, 57; strangulated Hium, disease of the bores of, 517, femoral, 153; memoir on inguino-intestinal,

Hip-joint, diseases of, lectures on, 482, 528. Hirsch, Dr., on thymic asthma, 201.

Hippocrates, life and doctrines of, 773

Hodgson, Mr., case by, of phlegmasia dolens,

Home, Sir E., one of the caustic bougie cases of, 770.

Hooper, Mr., note from, 349.

Horse, loss of the tongue in, 626.

Hopital des Enfans Malades, Paris, cases at, and remarks on, by Dr. Green:-Croup, 29; Insune, abolition of irons in the treatment of trachectomy in croup, 29; autopsy in croup, 31; lavyngo-tracheitis mistaken for, 54 N meningitis of the convexity of the brain, Instinct of animals, 107, 56; of the base of the brain, 37; tubercular meningitis in a child after measles, 492; bercular meningitis in a child after plathisis, 573; tubercular threaded by small-pox, 780;

arocephalis, 7815 typhus fever in the

e-pericarditis, 939; labeler passimonic with levingsth and demodsitis, 940. Hospital irresponsibility, 139; functionaries,

attendence of, 668; Semaritan Society.

Haspitals and Behools of Medicine, in London, but of open to students in the session 1855-36, 1.

Housenan and Dechambre, MM., on the disenes of old persons, 705.

louse of Commons, discussion on the Medired Witnesses Bill in, 905; remarks on discussion at, 913.

House-surgeon, election of one, by concours, 909.

Alusaland's Journal, 500; elizir for catarrh, 264.

Humerus, dialocation of, on the dorsum scapulm, 758.

Hydriodate of potash, in pain of the head, 274; in lupiform syphilis, 628; in syphilis, 743; in malignant, fungous, and cancerous diseases, 894.

Hadrophobia, case frequently simulating, 25: remarks on the article of Mr. Youatt on, by Mr. Varence, 26.

Hygiene, lecture on, 240; history of, 775. of Hygieniats of old, 241.

Hypertrophy of the cerebrum and cerebellum, 761 (see Andral, M.; Dr. Carswell on, 967.

1

Illusion of the mind, in delirium tremens, 227.

Infants, remittent fever of, 99, 293; diminution of mortality of, 691; scalded glottis in, 958.

Inflammation, Mr. Searle on, 26; and morbid vascularity, 311; and fever, Dr. Bow on,

Inglis, Dr., on cases mistaken for croup, 497; on a case of aphonia, 903.

Inquest, verdict at, without evidence, 88; at Farnham, 257, 263; on a fatally flogged soldier. 875.

the, 457; gangrene of the lungs in, 793. Insanity, following wounds of the head, 828.

Instruction, clinical, Mr. Travers on, 276. Intellect, derangement of, from sabre wounds of the head, 828.

INTERCEPTED LETTERS:-

Retreat into the country; thoughts at a distance from the profession; affairs at Windsor; changes in medical practice; country amusements; royal fun; the

markets; Dr. Wendrop on bleeding,
